

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

UNIVERSAL KNOWLEDGE FOR THE PEOPLE

NUMISMATICS.

NUMISMATICS (Lat. *nummus* and *numisma*, money; Gr. *nomisma*, from *nomos*, law, a medium of exchange established by law), the science which treats of coins and medals. A coin is a piece of metal of a fixed weight stamped by authority of government, and employed as a circulating medium. A medal is a piece struck to commemorate an event. The study of numismatics has an important bearing on history. Coins have been the means of ascertaining the names of forgotten countries and cities, their position, their chronology, the succession of their kings, their usages civil, military, and religious, and the style of their art. On their respective coins we can look on undoubtedly accurate representations of Mithridates, Julius Caesar, Augustus, Nero, Caracalla, and read their character and features.

The metals which have generally been used for coinage are gold, silver, and copper. In each class is comprised the alloy occasionally substituted for it, as electrum (an alloy of gold and silver) for gold, billon for silver, bronze for copper, and potin (an alloy softer than billon) for silver and copper. The side of a coin which bears the most important device or inscription is called the *obverse*, the other side the *reverse*. The words or letters on a coin are called its inscription; an inscription surrounding the border is called the *legend*. When the lower part of the reverse is distinctly separated from the main device, it is called the *exergue* (Gr. *ex ergou*, without the work), and often bears a secondary inscription, with the date or place of mintage. The field is the space on the surface of the coin unoccupied by the principal device or inscription.

The use of coined money cannot be traced further back than the 9th c. B.C. Money, however, as a medium of exchange, existed much earlier, and when of metal it passed by weight, no piece being adjusted to any precise weight, and all money being weighed when exchanged. Early metallic money was in the form of bars, spikes, and rings; the ring

money could be opened, closed, and linked in a chain for convenience of carriage.

The Lydians are supposed to have been the first people who used coined money, about 700 or 800 years before the Christian era; and their example was soon after followed by the different states of Greece, the earliest Greek coins being those of *Egina*. In its early stages the process of coining consisted in placing a lump of metal of a fixed weight, and approaching to a globular form, over a die, on which was engraved the religious or national symbol to be impressed. A wedge or punch placed at the back of the metal was held steadily with one hand, and struck by a hammer with the other, till the metal was sufficiently fixed in the die to receive a good impression. The impression was a guarantee of the weight of the piece. From the nature of the process, the earliest coins had a lumpy appearance, and on their reverse was a rough, irregular, hollow square, corresponding to a similar square on the punch, devised for the purpose of keeping the coin steady when struck by the coining hammer. The original coins of Asia Minor were of gold, those of Greece of silver. The earliest coins bear emblems of a sacred character, often embodying some legend regarding the foundation of the state, as the *phoca* or seal on the coins of the Phocians, which alludes to the shoal of seals said to have followed the fleet

Fig. 1.

during the emigration of the people. Fig. 1. represents a very early double stater of Miletus, in Ionia, of which the type is the lion's head, derived

from Persia and Assyria, and associated with the worship of Cybele, a symbol which is continued in the later coinage of Miletus. Types of this kind were succeeded by portraits of protecting deities. The earliest coins of Athens have the owl, as type of the goddess Athene; at a later period, the head of the goddess herself takes its place, the owl afterwards re-appearing on the reverse. The punch-mark, at first a rudely-roughed square, soon assumed the more sightly form of deep, wedge-like indents, which in later specimens become more regular, till they form themselves into a tolerably symmetrical square. In the next stage, the indents become shallower, and consist of four squares forming one large one.

Fig. 2.

The surrounding of the punch-mark with a band bearing a name, and the introduction of a head in its centre, as in the annexed figure (fig. 2), gradually led to the perfect reverse. There is a remarkable series of so-called 'encased' coins struck in Magna Græcia, of which the reverse is an exact repetition in concave of the relief of the obverse. These coins are thin, flat, sharp in

relief, and beautifully executed.

The leading coin of Greece and the Greek colonies was the stater, so called because founded on a standard of weight generally received before the introduction of coined money. There were double staters, and half, third, and quarter staters, and the stater was equivalent in value to six of the silver pieces called drachmæ. The obolus was one-sixth of the drachma, at first struck in silver, in later times in copper.

The inscriptions on the earliest Greek coins consist of a single letter, the initial of the city where they were struck. The remaining letters, or a portion of them, were afterwards added, the name, when in full, being in the genitive case. Monograms sometimes occur in addition to the name, or part name, of the place. The first coin bearing the name of a king is the tetradrachm (or piece of four drachmæ) of Alexander I. of Macedon.

Among the early coins of Asia, one of the most celebrated is the stater Daricus or Daric, named from Darius Hystaspes. It had for symbol an archer kneeling on one knee, and seems to have been coined for the Greek colonies of Asia by their Persian conquerors. In the reign of Philip of Macedon, the coinage of Greece had attained its full development, having a perfect reverse. One of the earliest specimens of the complete coin is a beautiful medal struck at Syracuse, with the head of

Fig. 3.

Proserpine accompanied by dolphins, and for reverse a victor in the Olympic games in a chariot receiving a wreath from Victory—a type which is also found

on the reverse of the staters of Philip of Macedon, known as Philips, and largely imitated by other states. Coins of Alexander the Great are abundant, many having been struck after his conquests in the Greek towns of Asia. A rose distinguishes those struck at Rhodes, a bee those struck at Ephesus, &c.; these are all types generally accompanying the figure of Zeus on the reverse; on the obverse is the head of Hercules, which has sometimes been supposed to be that of Alexander himself. It would rather seem, however, that the conqueror's immediate successors were the first who placed their portrait on the coins, and that under a shallow pretence of deification, Lyzimachus as a descendant of Bacchus, and Seleucus of Apollo, clothed in the attributes of these deities. Two most beautiful and important series of Greek coins are those of the Seleucids, in Asia, of silver, and of the Lagids or Ptolemies, in Egypt, of gold.

In Palestine there is an interesting series of coins founded on the religious history of the Jewish nation, and assigned to Simon Maccabæus. They are shekels and half-shekels, equivalent to two Attic drachmæ and one drachma respectively. The shekels bear on the obverse the pot of manna, with the inscription 'Schekel Israel' (the Shekel of Israel); on the reverse is Aaron's rod with three flowers, and the legend 'Ierouschalim kedoshah' (Jerusalem the Holy). The inscriptions are in the Samaritan character. The successors of Simon assumed the title of king, and placed their portraits on the coins, with inscriptions in Greek as well as in Hebrew.

Roman coins belong to three different series, known as the Republican, the Family, and the Imperial.

The so-called Republican, the earliest coinage, began at an early period of Roman history, and subsisted till about 80 B.C. Its standard metal was copper, or rather *æs* or bronze, an alloy of

Fig. 4.

copper. The standard unit was the poundweight divided into twelve ounces. The *æs*, or *as*, or pound of bronze, is said to have received a state impress as early as the reign of Servius Tullius, 578 B.C. This gigantic piece was oblong like a brick, and stamped with the representation of an ox or sheep, whence the word *pecunia*, from *pecus*, cattle. The full pound of the *as* was gradually reduced, always retaining the twelve (nominally) uncial subdivisions, till its actual weight came to be no more than a quarter of an ounce. About the time when the *as* had diminished to nine ounces, the square form was exchanged for the circular. This large copper coin, called the '*as grave*,' was not struck with the punch, but cast, and exhibited on the obverse the Janus bifrons; and on the reverse, the prow of a ship, with the numeral I. Of the fractions of the *as*, the sextans, or sixth part, generally bears the head of Mercury, and the uncia, or ounce piece (fig. 4), that of Minerva; these pieces being further

distinguished by dots or knobs, one for each ounce. There were circular pieces as high as the decussis, or piece of twelve asses, presenting a head of Roma (or Minerva), but none are known to have been coined till the weight of the as had diminished to four ounces. The Roman uncial coinage extended to the other states of Italy, where a variety of types were introduced, including mythological heads and animals. In the reign of Augustus, the as was virtually superseded by the sestertius, called by numismatists the first bronze, about the size of our penny, which was at first of the value of 2½, afterwards of 4 asses. The sestertius derived its value from the silver denarius, of which it was the fourth. The half of the sestertius was the dupondius (known as the second bronze), and the half of the dupondius was called the assarium, an old name of the as. The assarium is known to numismatists as the third bronze.

Silver was first coined at Rome about 281 B.C., the standard being founded on the Greek drachma, then equivalent in value to ten asses; the new coin was therefore called a denarius, or piece of ten asses. The earliest silver coined at Rome has on the obverse the head of Roma (differing from Minerva by having wings attached to the helmet); on the reverse is a quadriga or biga, or the Dioscuri. Among various other types which occur in the silver of the Italian towns subject to Rome are the horse's head, and galloping horse, both very beautiful. During the social war, the revolted states coined money independently of Rome, and used various devices to distinguish it as Italian and not Roman money.

The earliest gold coins seem to have been issued about 90 B.C., and consisted of the scrupulum, equivalent to 20 sestertii, and the double and treble scrupulum. These pieces bear the head of Mars on the obverse, and on the reverse an eagle standing on a thunderbolt, with the inscription 'Roma' on the exergue. The large early republican coins were cast, not struck.

The Family Coins begin about 170 B.C., and about 80 B.C. they entirely supersede the coins first described. Those families who successively held offices connected with the public mint acquired the right first to inscribe their names on the money, afterwards to introduce symbols of events in their own family history. These types gradually superseded the natural ones; the portrait of an ancestor followed; and then the portrait of a living citizen, Julius Cæsar.

Under the empire, the copper sestertius, which had displaced the as, continued the monetary standard. A magnificent series exists of the first bronzes of the emperors from Augustus to Gallienus. While it was the privilege of the emperors to coin gold and silver, copper could only be coined *ex senatusconsulto*, which from the time of Augustus was expressed on the coins by the letters S.C., or EX S.C. The obverse of the imperial coins bears the portraits of the successive emperors, sometimes of the empress or other members of the imperial family; and the reverse represents some event, military or social, of the emperor's reign, sometimes allegorised. The emperor's name and title are inscribed on the obverse, and sometimes partly continued on the reverse; the inscription on the reverse generally relates to the subject delineated; and towards the close of the 3d c., the exergue of the reverse is occupied by the name of the town where the coin is struck. The coins of Augustus and those of Livia, Antonia, and Agrippina the Elder have much artistic merit. The workmanship of Nero's sestertii is very beautiful. The coins of Vespasian and Titus commemorate the conquest of

Judæa. The Colosseum appears on a sestertius of Vespasian. The coins of Trajan are noted for their architectural types. Hadrian's coins commemorate his journeys. The coins and medals of Antonine, Marcus Aurelius, and the two Faustine are well executed; as are also those of Commodus, of whom a remarkable medallion relates to the conquest of Britain. There is a rapid falling off in design after the time of Commodus, and base silver comes extensively into use in the reign of Caracalla. Gallienus introduced the practice of coining money of copper washed with silver.

The colonial and provincial money of this period was very inferior to that coined in Rome. In the coins of the provinces which had been formed out of the Greek empire, the obverse bears the emperor's head, and the reverse generally the chief temple of the gods in the city of coinage; the inscriptions are in Greek. In the imperial coins of Alexandria appear such characteristic devices as the heads of Jupiter Ammon, Isis, and Canopus, the sphinx, the serpent, the lotus, and the wheat-ear. Colonial coins were at first distinguished by a team of oxen, afterwards by banners, the number of which indicated the number of legions from which the colony had been drawn.

After the time of Gallienus, the colonial money and the Greek imperial money, except that of Alexandria, ceased, and much of the Roman coinage was executed in the provinces, the name of the town of issue appearing on the exergue. Diocletian introduced a new piece of money, called the follis, which became the chief coin of the lower empire. The first bronze has disappeared after Gallienus, and the second disappears after Diocletian, the third bronze diminishing to 1/16th of an ounce. With the establishment of Christianity under Constantine, a few Christian types are introduced. The third bronze of that emperor has the Labarum (q. v.), with the monogram IHS. Large medallions, called *contorniaci*, encircled with a deep groove, belong to this period, and seem to have been prizes for distribution at the public games. Pagan types recur on the coins of Julian; and after his time the third bronze disappears.

The money of the Byzantine empire forms a link between the subject of ancient and that of modern coins. The portrait of the emperor on the obverse is after the 10th c. supported by some protecting saint. The reverse has at first such types as Victory with a cross, afterwards a representation of the Saviour or the Virgin; in some instances, the Virgin supporting the walls of Constantinople. Latin is gradually superseded by Greek in the inscriptions, and wholly disappears by the time of Alexius I. The chief gold piece was the solidus or nomisma, which was long famed in commerce for its purity, and circulated largely in the west as well as the east of Europe.

Of the coins of the middle ages, the most important is the silver denier or penny, derived from the Latin denarius. Its half was the obole, first of silver, afterwards of billon. Coins of this description were issued in the German empire, France, England, and the Scandinavian states, and in many cases by ecclesiastical princes and feudal lords as well as sovereigns. The obverse of the regal coin of the early middle ages is generally the bust of the sovereign, and the reverse a Greek cross, accompanied by the royal name or title, and the place of mintage or the moneyer (see *MINT*). The arms of the country were introduced in the 12th c., in conjunction with the cross, and afterwards superseded it. In the 13th and 14th centuries, coins began to be issued by free imperial cities or corporations of towns; and there prevailed extensively throughout

Germany and other parts of Europe a thin piece called a bracteate, in relief on one side, and hollow on the other, often not bearing a single letter, and rarely a full inscription. Down to the 14th c., the relief of the mediæval coins is very inconsiderable, the pieces thin, and the art poor.

Britain received the Roman money on its subjugation. Constantine seems to have had a mint in London, and the Roman currency continued to circulate for a time after the departure of the conquerors. The first independent coinage, however, shews hardly a trace of the influence of Rome; it consists of two small coins, called the *skeatta* and *styca*, the former of silver, the latter of copper. Both seem to belong solely to the Saxon kingdom of Northumbria; they are without inscriptions; a bird, a rude profile, and several unintelligible symbols appear on them, and their art is of the most debased kind. In the other kingdoms of the heptarchy silver pennies were coined, first intended to be $\frac{1}{24}$ th of a pound weight; on the disappearance of *skeatts* and *stycas*, they form, with the occasional addition of halfpennies, the sole currency of England down to the reign of Edward III. The pennies of the heptarchy bear the name of the king or of the moneyer; a cross sometimes appears after the introduction of Christianity, and in later times a rude head of the king or queen. The pennies of the Saxon and Danish sole monarchs of England, have a somewhat similar character. Alfred's earlier coins have a grotesque-looking portrait, and on the reverse

Fig. 5.

a monogram of London; in his later coins the head disappears, and a cross and circle take its place. A cross, variously ornamented with three pellets in each angle, continues to be the usual reverse of the Saxon, Norman, and Plantagenet coins. The coins of Edward III. are a great artistic advance on those that preceded them. The silver coinage of that king consisted not only of pennies, halfpennies, and farthings, but also of groats and half-groats. The obverse of the groat bears a conventional crowned head within a flowered circle of nine arches, the words '*Dei Gratia*' and the title '*Rex Francie*' appearing for the first time in the legend. The reverse has the motto '*Posui Deum adiutorem meum*,' which continued on the coinage till the time of Edward V. But the great numismatic feature of Edward III.'s reign is the issue of gold nobles, worth six shillings and eightpence. The obverse of those beautiful coins represent the king in a ship, a sword in his right hand, in his left a shield with the quartered arms of France and England. The reverse is a rich cross flory within a circle of eight arches, and a lion under a crown in each angle of the cross, the legend being '*Ihesus autem transiens per medium illorum ibat*.' Half and quarter nobles were also coined. The noble having increased in value, a coin called an angel, of the former value of a noble, was issued by Henry VI. and Edward IV. The obverse represented St Michael transfixing a dragon; the reverse a ship, with a cross for the mast.

As we approach the period of the Reformation, the coinage gradually becomes more ornate. The nobles coined by Edward IV., after the value

of that coin had been fixed at ten shillings, were called *rials* (a name derived from a French coin), and the double rial or sovereign was first coined by Henry VII. The obverse has the king on his throne with sceptre and orb, and on the reverse, in the centre of a heraldic full-blown rose, is a shield with the arms of France and England. The testoon, or shilling, valued at twelve pence, also first appeared in this reign, with the royal profile crowned on the obverse, and the royal arms quartered by the cross on the reverse. A great debasement of the coinage took place in the reign of Henry VIII. The reverse of the farthings of that monarch bears a portcullis, that of the shillings a rose surmounted by a crown, and of the sovereigns, the royal arms supported by a lion and dragon. A noble was coined with St George and the dragon on the obverse, and on the reverse a ship with three crosses for masts, and a rose on the centre mast. On the coins of Henry VIII. the title '*Hibernie Rex*' first appeared, former kings having only styled themselves '*Dominus Hibernie*,' Ireland not being accounted a kingdom. Under Edward VI., the silver coins called crowns and half-crowns appear, having for device the king crowned on horseback in the armour of the period. They derived their name from coins circulating on the continent, which had for device a crown. The royal arms in an oval shield without the cross are introduced as the reverse of the shilling. From this period there is a very obvious decline in the artistic feeling of the English coins. On some of the shillings of Mary, her bust and that of Philip face each other, the insignia of Spain and England impaled occupying the reverse; afterwards the king's head occupies one side of the coin, and the queen's the other. Half-sovereigns, or rials, and angels were coined of the old type of Edward IV. The great event in the coinage of Elizabeth's reign was the temporary introduction of the mill and screw, instead of the hammer and punch, producing coins of a more regular and workmanlike appearance. The profile bust of James I., crowned and in armour, appears on his shillings and smaller pieces; on his crowns and half-crowns he is represented on horseback; on the reverse are the quartered arms of the three kingdoms (the harp of Ireland appearing for the first time on the coinage), with the motto '*Que Deus conjunxit nemo separet*.' Copper farthings, with crown, sceptre, and sword on the obverse, and a harp on the reverse, were coined for England as well as Ireland, the first copper money issued in England since the *styca*. Private tokens of copper, issued by tradesmen and others, had, however, been in circulation before, and came again into use to a large extent at a later period. Charles I. coined ten and twenty shilling pieces of silver, the former a very noble coin, with a representation of the king on horseback. A crown, struck at Oxford, bears on the obverse the king on horseback, with a representation of the town, and on the reverse the heads of the Oxford declaration. The guinea, first coined in this reign, was so called from the metal being procured from the coast of Guinea; its original value was but twenty shillings.

The coins of the Commonwealth exhibit a shield with the cross of St George surrounded by a palm and olive branch, and have for legend '*The Commonwealth of England*.' On the reverse are two shields accollée, with the cross of St George and the harp of Ireland, and the motto '*God with us*.' Coins far superior in character were executed by Cromwell, with his laureated bust and title as Protector, and on the reverse a crowned shield quartering the cross of St George, of St Andrew and the harp, with the Protector's paternal arms in surcoat; but few of these were issued. In the early

coins of Charles II., that monarch is crowned, and in the dress of the time; in his later money he is in conventionalised Roman drapery, with the head turned to the left, and from that time it has been the practice to turn every king's head the reverse way from that of his predecessor. The four shields on the reverse are disposed in the form of a cross (an arrangement which continued till the reign of George II.), and on the edge of the crowns and half-crowns is the legend 'Decus et tutamen.' Charles II. issued a copper coinage of halfpennies and farthings; on the former appears the device of Britannia, taken from the Roman coins relating to Britain. Pennies were not coined till George III.'s reign. The coins of William and Mary have the profiles of the king and queen one over the other, and the shields of the three kingdoms in the form of a cross on the reverse, with Nassau in the centre. The coinage of William alone, after the death of Mary, is of somewhat improved design, Sir Isaac Newton being then Master of the Mint. Little change in the general design of the coin occurs in the reigns of Anne and George I. On the accession of the House of Hanover, the Hanoverian arms are placed in the fourth shield, and George IV. substituted a quartered shield with Nassau en surtout for the four shields on the reverse of his gold coins. During the greater part of George III.'s reign the coinage was utterly neglected, and the silver pieces in circulation were worn perfectly smooth. When coins were at last issued, the Roman conventionalism of the previous reigns gave way to a now fashionable Greek conventionalism. The quartered shield supplanted the four shields, and on the reverse of the crown appeared a Grecianised St George and the dragon. George IV.'s bust is taken from Chantrey's statue; the rose, thistle, and shamrock, united under a crown, appear on the reverse of his shilling. Silver groats were issued in the reign of William IV. The ensigns of Hanover disappeared at the beginning of the present reign; the reverse of the shilling is even poorer than that of George IV., the words 'One shilling' occupy the field, surrounded by an oak branch and a laurel branch; silver pieces of three-pence have been introduced. But the principal monetary event is the issue of the silver florin, in value equivalent to two shillings, looked on as a step towards the institution of a decimal coinage. It represents the head of the Queen crowned, with the legend in old English character, and for reverse the four shields are once more placed in the form of a cross.

No native Scottish coinage existed earlier than the 11th century. Coins are extant of Somerled, prince of the Isles of that century, and of Alexander I. of the century following. The silver pennies of William the Lion, and Alexander II. and III., are like contemporary English money, but ruder, and bear the names of the moneymen and place of mintage, generally Edinburgh, Perth, or Berwick. The profiles on the coins of John Baliol, Robert Bruce, and David II. are attempts at portraiture. A remarkable gold piece, first coined by Robert II., is the St Andrew, with the arms of Scotland on the obverse, and St Andrew on his cross on the reverse. In the four succeeding reigns the weight of the silver coins rapidly decreased, and coins of billon, or base metal, were issued, nominally pennies, but three and a half of which eventually passed for a silver penny. The evil increased, and baser and baser alloy was used. Groats of billon, known as placks and half-placks, were coined by James III. James IV.'s coins have a characteristic portrait, and a good deal of artistic feeling. James III. and IV. issued well-executed gold pieces, called unicorns and riders, the type of

the one being the unicorn, of the other the king on horseback. A still more beautiful coin was the gold bonnet piece of James V., so called from the cap in the king's portrait. Of Mary, there are a great variety of interesting pieces. The portrait is sometimes crowned, sometimes uncrowned, and on the coin issued soon after Francis's death, has a widow's cap and high-frilled dress. The types in James VI.'s reign are also very various. On his accession to the English throne, the relative value of English and Scottish coins was declared to be as 12 to 1. The coins afterwards issued from the Scottish mint differed from the English, chiefly in having Scotland in the first quarter in the royal shield. The last Scottish gold coinage consisted of pistoles and half-pistoles of Darien gold, about the size of a guinea and half-guinea, struck by William III.; the pistole distinguished by a rising sun under the bust of the king.

The coinage of Ireland is scanty and uninteresting compared with that of Scotland. The coins of English monarchs struck in Dublin resemble much those current in England. Henry VIII. first placed a harp on the Irish coins.

In France, the earliest coins are those of the Merovingian kings, rude imitations of the late Roman and early Byzantine money, and mostly of gold. Under the Carlovingian dynasty, deniers and oboles are the prevailing coinage, remarkably rude in fabric, without portrait, and bearing the name of the king and place of mintage. Some coins of Charlemagne, struck at Rome, are of better workmanship. They contain one letter of 'Roma' at each extremity of the cross, with the legend 'Carolus IP.' The coinage improved under the Capetian kings; the fleur-de-lis appears in addition to the cross. In the 13th c. gold pieces were issued, and in the time of Philip VI. both the design and the execution of the coins are beautiful. The coins of Louis XII. are the first that bear the royal portrait. The modern coinage may be said to begin under Henry II., whose portrait is good. The seigniorial coins of France in the middle ages are of considerable importance, and the medals of Louis XIV. and Napoleon I. are much more interesting than the modern coins.

The mediæval coinage of Italy is of great interest. The money of the Lombard kings of Italy and Dukes of Benevento, is little inferior to that of the Greek emperors. There is a beautiful series of gold and silver pieces belonging to Venice, bearing the names of the doges, and having generally for type the doge receiving the gonfalon, or standard of St Mark. The gold florins of Florence, with the lily for device, are no less celebrated, and were imitated by other states. Florence had also a remarkable series of medals, with admirable portraits of persons of note. The coins of the popes, from Hadrian I. down to the 14th c., bear the name of the pope and emperor of the west; those of later date are beautiful in execution, and have seated portraits of the pontiffs, with the cross-keys and mitre for reverse. A remarkable series of medals commemorates the chief events of each reign, one of which, struck after the massacre of St Bartholomew, has for type an angel slaying the Huguenots, and the inscription 'Ugonottorum strages.' The coins of the Norman princes of Naples struck in Sicily, have the legends partly or wholly in Arabic. Malta has a series, with the arms and effigies of the grand-masters.

The mediæval money of Germany comprises coins of the emperors, the electors, the smaller princes, the religious houses, and the towns. The imperial series is extensive and very interesting, though, till near the close of the middle ages, it is rather backward in its art. About the Reformation period,

however, there are vigorous portraits both on its current coins and on the medals, and those double dollars which are virtually medals. The coins of the Dukes of Saxony, with their portraits, are equally remarkable. The coins of the archbishops of Cologne, Mainz, and Treves form a very interesting series, the first more especially, with a representation of the cathedral.

The coins of the Low Countries resemble those of France and Germany. The Dutch medals are of interest, more especially those struck in commemoration of events in the war with Spain.

The coins of the Swiss cantons and towns during the early period of Swiss independence bore the heraldic shield of each, drawn with vigorous grotesqueness. There are also pieces struck by ecclesiastical lords, and by different families who had a right of coinage.

The coins of Spain begin with those of the Gothic princes, which are chiefly of gold, and on the model of the trientes and semisses of the lower empire. Some of the early pieces have a rude head of the monarch on one side, and of the emperor on the other. Afterwards, the obverse bears the profile of the monarch, and the reverse a cross of some description, with the name of the place of mintage, and the word 'Pius' for legend. In later times, there are two interesting series of coins belonging to the kingdom of Aragon and to the kingdom of Castile and Leon.

The coinages of Norway and Sweden at first resembled the British, and afterwards the German type. From the 10th to the 14th c., bracteates were issued by the ecclesiastics. The coinage of Hungary begins in the 11th c., and has the portraits of the monarchs. The Russian coinage is Byzantine in character, and rude in its art. The earliest pieces are the silver darga of the 14th c., of an oblong shape, with representations of the prince on horseback, and various legendary subjects. Peter the Great introduced the usual European type. There is an important series of bronze coins of the Crusaders, beginning with Tancred, and coming down to the end of the 16th c., including money of the kings of Cyprus and Jerusalem, and other princes established in the east.

In India, the succession of the kings of Bactria, the remotest of the dynasties founded on the ruins of Alexander's empire, has only become known through their recently-discovered coins. There are early rude Hindu coins of the Gupta line, with figures of the Brahminical divinities of a type still in use.

Of the coins of the Mohammedan princes, the oldest gold pieces are the bilingual coins of cities of Syria and Palestine, of the middle of the 7th c. (A. H. 78), barbarous imitations of the latest Byzantine money of Alexandria. Most of the Mohammedan coins are covered exclusively by inscriptions expressive of the elementary principles of the Mohammedan faith. For some centuries, no sovereign except the calif was allowed to inscribe his name on the coin. Large gold coins of great purity were issued by the Moslem kings of Granada in Spain.

The high prices given for ancient coins have led to numerous forgeries from the 15th c. downwards. Against such imitations, collectors require to be on their guard.

Among the best works on numismatics are Eckhel, *Doctrina Numorum Veterum* (Vienna, 1792—1798); Hennen, *Manuel de Numismatique Ancienne* (Paris, 1830); Grasset, *Handbuch der alten Numismatik* (Leipzig, 1852—1853); Leake, *Numismata Hellenica* (London, 1854); Ruding's *Annals of*

the Coinage of Great Britain (London, 1840); Patrick's *Records of the Coinage of Scotland* (1877); Leblanc, *Traité Historique des Monnoies de France* (Paris, 1690); Cappe, *Die Münzen der Deutschen Kaiser* (1850); Marsden, *Numismata Orientalia Illustrata* (London, 1823—1825); Boutkovski, *Dictionnaire Numismatique* (Leipzig, 1877).

NUMMULITE LIMESTONE, an important member of the Middle Eocene period, consisting of a limestone composed of nummulites held together by a matrix formed of the comminuted particles of their shells, and of smaller foraminifera. It forms immense masses of the strata which are raised up on the sides of the Alps and Himalayas, and may be traced as a broad band often 1800 miles in breadth, and frequently of enormous thickness, from the Atlantic shores of Europe and Africa, through Western Asia, to Northern India and China. It is known also to cover vast areas in North America.

NUMMULITES, or **NUMMULINA** (Gr. money-fossil), a genus of fossil foraminifera, the shells of which form immense masses of rock of Eocene age. See **NUMMULITE LIMESTONE**. Upwards of 50 species have been described. They are circular bodies of a lenticular shape, varying in magnitude from the merest point to the size of a crown-piece. The shell is composed of a series of small chambers arranged in a concentric manner. The growth of the shell does not take place only around the circumference, but each whorl invests all the preceding whorls, so as to form a new layer over the entire surface of the disk, thus adding to the thickness as well as the breadth, and giving the fossil its lenticular form. A thin intervening space separates each layer from the one which it covers, and this space at the margin swells out to form the chamber. All the internal cavities, however, seem to have been occupied with the living sarcodæ, and an intimate connection was maintained between them by means of innumerable parallel tubuli, which everywhere pass from one surface to another, and which permitted the passage of the sarcodæ as freely as do the minute pores or foramina of the living foraminifera.

The name is given to them from their resemblance to coins. In Egypt, where the whole of the Mokkadam Mountains, from the stone of which the pyramids were built, is formed of them, they are called by the natives 'Pharaoh's Pence.'

NUN, a member of a religious order of women. The etymology of this name is a subject of some controversy, but there seems every reason to believe that it is from a Coptic or Egyptian root, which signifies 'virgin.' It is found in use as a Latin word as early as the time of St Jerome (*Ep. to Eustachius*, p. 22, c. 6). The general characteristics of the religious orders will be found under the head **MONACHISM** (q. v.), and under those of the several orders. It is only necessary here to specify a few particulars peculiar to the religious orders of females. Of these the most striking perhaps is the strictness in the regularly authorised orders of nuns of the 'cloister,' or enclosure, which no extern is ever permitted to enter, and beyond which the nuns are never permitted to pass, without express leave of the bishop. The superiors of convents of nuns are called by the names Abbess, Prioress, and, in general, Mother Superior. They are, ordinarily speaking, elected by chapters of their own body, with the approval of the bishop, unless the convent be one of the class called exempt houses, which are immediately subject to the authority of the Holy See. The ceremony of the solemn blessing or inauguration of the abbess is reserved to the bishop, or

to a priest delegated by the bishop. The authority of the abbess over her nuns is very comprehensive, but a precise line is drawn between her powers and those of the priestly office, from which she is strictly debarred. The name of nun is given in general to the sisters of all religious congregations of females who live in retirement and are bound by rule; but it is primitively and properly applicable only to sisters of the religious orders strictly so called. See **MONACHISM**.

NUNC DIMITTIS, the name given to the canticle of Simeon (Luke ii. 29—32), which forms part of the compline office of the Roman Breviary, and is retained in the evening service of the Anglican Church when it follows the second lesson. On the great festivals in Lent, the music of this canticle is especially grand and imposing.

NU'NOIO (Ital. *nunzio*, Lat. *nuncius*, a messenger), the name given to the superior grade of the ambassadors sent by the pope to foreign courts, who are all called by the general name of **LEGATE** (q. v.). A nuncio is an ambassador to the court of an emperor or king. The ambassador to a republic, or to the court of a minor sovereign, is called **INTER-NUNCIO**.

NUNCUPATIVE WILL is a will made by word of mouth. As a general rule, no will is valid unless it is in writing and signed by the testator; but in cases of soldiers and sailors, a verbal or nuncupative will is held to be good, on the ground that there is often no time to draw up a formal will in writing.

NUNEATON, a small market-town of England, in the county of Warwick, and 18 miles north-east of the town of that name. It contains a small parish church in Gothic, and its Free Grammar School was founded by Edward VI. in 1553. Ribbons and cotton goods are manufactured. Pop. (1871) 7000; (1881) 8465.

NUNQUAM INDEBITATUS, a law term meaning, in an action for debt, a plea that the defendant never was indebted. By the Judicature Act of 1875, the defendant is no longer allowed to deny generally the facts alleged by the plaintiff.

NURAGHE, the name of certain structures, of conical shape, in the island of Sardinia, rising 30 or 40 feet above the ground, with two or three stories of domed chambers connected by a spiral staircase.

View of the Nuraghe of Goni, in Sardinia.

Some are raised on basements of masonry, or platforms of earth. They are made of granite limestone, basalt, porphyry, sandstone, and schist. Their entrances are small and low, and when they have

chambers of two stories, the upper chamber is reached by the spiral staircase which has loopholes to admit the light. The tops are supposed to have had a terrace. Although 3000 of them exist, none are perfect. Their masonry is irregular, but not polygonal, and resembles the style of work called

Plan and Elevation of the Nuraghe of Goni, in Sardinia.

Asiatic. Like the round towers of Ireland, and other uninscribed monuments, their object and antiquity are enveloped in much doubt. They have been supposed to be the work of the Pelasgi, the Phœnicians, or Carthaginians, and to have been ancient sepulchres, *Tholi* or *Daedalia*, constructed in heroic times. Skeletons, and other funeral paraphernalia, have been found in them. They have many points of resemblance to the 'Burghs' or 'Duns' on the northern shores of Scotland, of which the Burgh of Mousa, in Shetland, is perhaps the best example.—De la Marmora, *Voyage en Sardaigne*, tom. ii.; Petit Radet, *Nuraghes* (Paris, 1828); Dennis, *Cities and Cem. of Etruria*.

NÜRNBERG (*Norimberga*, *Norica*), a city of the Bavarian province of Middle Franconia, in a sandy but well-cultivated district on the Pegnitz River (ultimately joining the Main). Pop., mostly Protestants, (1881) 99,519; with suburbs, 103,677. N. is one of the most remarkable and interesting cities of Germany, on account of the numerous remains of mediæval architecture which it presents in its picturesque streets, with their gabled houses, stone balconies, and quaint carvings. No city retains a stronger impress of the characteristics which distinguished the wealthy burgher-classes in the middle ages, while its double lines of fortified walls, separated from each other by public walks and gardens, and guarded by 70 towers, together with the numerous bridges which span the Pegnitz, on whose banks the city is built, give it distinctive features of its own. Among the most remarkable of its numerous public buildings are the old palace or castle, commanding, from its high position, a glorious view of the surrounding country, and interesting for its antiquity, and for its gallery of paintings, rich in gems of early German art; the town-hall, which ranks amongst the noblest of its kind in Germany, and is adorned with works of Albert Dürer and Gabriel Weyher; the noble Gothic fountain opposite the cathedral by Schonhofer, with its numerous groups of figures, beautifully restored in modern times; and many other fountains deserving notice. Of the numerous churches of N., the following are the most remarkable: St Lawrence, built between 1270—1478, with its beautiful painted-glass windows, its noble towers and doorway, and the celebrated stone pyx, completed in 1500, by Adam Kraft, after five years' assiduous labour; and the

exquisite wood-carvings of Veit Stoss; St Sebald's, with its numerous fine glass-paintings and frescoes by Peter Vischer and other German masters; the cathedral, or Our Lady's, built in 1631, similarly enriched. N. is well provided with educational establishments, and besides a good gymnasium and polytechnic institution, has good schools of art, normal and other training colleges, a public library of 50,000 vols., galleries of art collections, museums, &c.; while the numerous institutions of benevolence are liberally endowed and well maintained. Although the glory of the foreign commerce of N. may be said to have been long extinct, its home trade, which is still of considerable importance, includes the specialties of metal, wood and bone carvings, and children's toys and dolls, which find a ready sale in every part of Europe, and are largely exported to America and the East. In addition to its own industrial commerce, is the seat of a large transfer and exchange business, which owes much of its importance to the facilities of intercommunication afforded by the net-work of railway lines with which the city is connected.

N. was raised to the rank of a free imperial city by the Emperor Frederick II., in 1219, 21 years before which date, Henry VI. is falsely said to have ennobled 38 of the burgher families, who forthwith arrogated supreme power over the N. territory. In the 13th c., we find it under the title of a burgraviate in the hands of the Hohenzollern family, who, in 1417, ceded for a sum of money all their territorial and manorial rights to the magistracy of the city. This measure put a stop to the feuds which had hitherto raged between the burgraves and the municipality, and for a time N. continued to grow rich with the fruits of the great internal trade, which it had long maintained between the traders of the East and the other European marts of commerce. The discovery of the passage by the Cape of Good Hope, by opening new channels of communication between Asia and Europe, deprived N. of its ancient monopoly. The Thirty Years' War completed the decay of the city, which suffered severely from both parties in turn. The ancient reputation of N. as a wealthy and loyal city of Germany secured to it, however, special consideration; and in 1803, when the imperial commissioners reorganised some of the dismembered parts of the old empire, it was allowed to retain its independence, with a territory of 483 square miles, containing 40,000 inhabitants, and drawing a revenue of 800,000 guildens; but in consequence of the disputes in which the free city became involved with the king of Prussia, who had some hereditary claim on the ancient burgraviate, N., alarmed at the prospect of still greater embarrassments, entered into the Rhenish Confederation, and as the result of this alliance, was transferred, in 1806, with the surrender of its entire domain and all rights of sovereignty, to the king of Bavaria.

NURSE, MILITARY. In continental armies, the 'sisters of charity' usually carry their mission of mercy into the military hospitals. Protestant England having no such organisation to fall back upon, the soldiers have been dependent on the regular male hospital attendants for their care during sickness, or when suffering from wounds. The Crimean campaign, however, disclosed so melancholy a picture of the want of women's co-operation, that a band of self-sacrificing ladies, headed by Miss Nightingale (q. v.), proceeded to Turkey, and were soon acknowledged as messengers of health and life by the unfortunate wounded. The example thus set has not been without effect. In the Franco-German war of 1870—1871, lady-nurses of various nations ministered in all the military hospitals,

and the like took place during the Russo-Turkish war of 1877—78.

NURSERY, a garden or portion of a garden devoted to the raising of young plants, to be afterwards planted elsewhere. The ripening of garden-seeds for sale is generally also an important part of the trade of the public nurseryman. Many culinary vegetables are very commonly raised from seed in public nurseries, and sold as young plants; the trouble of raising them in small gardens being found too great, although, when there is no public nursery at hand, even the cottage-gardener may be compelled to undertake this trouble for himself, in order to procure a supply of young kale, cabbage, cauliflower, &c., in fresh and healthful condition. Many flowering plants, as wallflower, stock, sweet-william, &c., are also raised and sold by nurserymen. Another great use of the nursery is the rearing of fruit-trees. In the nursery, the stocks are raised from seed, the grafting is performed, and the training of the young tree, whether for standard, espalier, or wall tree, is begun. As, with regard to fruit-trees, the selection of grafts is of the utmost importance, the reputation of the nurseryman is particularly to be considered by the purchaser; nor is there any trade in which this is more generally necessary, months, or sometimes years elapsing before the quality of the goods purchased can be experimentally ascertained. The principal, and many of the smaller towns of Britain are well supplied with public nurseries, which is the case also in many countries of continental Europe and in North America. Some of these nurseries are on a very great scale, as those of Messrs Loddige of London, Lawson of Edinburgh, and Booth of Hamburg. The largest nurseries, however, are very much devoted to the rearing of ornamental shrubs and trees, and of forest-trees. Plantations of forest-trees, even when very extensive, are now generally, although not always, made with plants obtained from public nurseries. The exertions made by nurserymen to obtain new plants from foreign countries, have contributed much, not only to the advancement of gardening in its various departments, and of arboriculture, but also of botany.—Much benefit also results from the exchange of the produce of the nurseries of different countries. Thus, bulbous roots are brought to Britain from Holland, from what may be described as nurseries specially devoted to them; roses and orange-trees are imported from the nurseries of France, &c. It often happens that seeds imported from climates more thoroughly adapted to the plants, produce better crops than those raised in a colder climate or under a cloudier sky.

NUT, in popular language, is the name given to all those fruits which have the seed enclosed in a bony, woody, or leathery pericarp, not opening when ripe. Amongst the best known and most valuable nuts are the Hazel-nut, Brazil nut, Walnut, Chestnut, and Cocoa-nut, all of which are edible. Other nuts are used in medicine, and for purposes connected with the arts. Some of the edible nuts abound in a bland oil, which is used for various purposes.—In Botany, the term nut (*nut*) is used to designate a one-celled fruit, with a hardened pericarp, containing, when mature, only one seed. The *Achenium* (q. v.) was by the older botanists generally included in this term. Some of the fruits to which it is popularly applied scarcely receive it as their popular designation. The hazel-nut is an excellent example of the true nut of botanists.—The name nut, without distinctive prefix, is popularly given in Britain to the hazel-nut, but in many parts of Europe to the walnut.

NUTATION—NUT-HATCH.

Many nuts have a considerable commercial value, from their being favourite articles of food : these are the Hazel-nut and its varieties, the Black Spanish, the Barcelona, the Smyrna, the Jerusalem filbert, and the common filbert ; the Walnut, Chestnut, Hickory, and Pecan ; the Souari, the Cocoa or Coker nuts, and the Brazil or Para nut.

The Barcelona and Black Spanish, as their names imply, are from Spain ; the former is the commonest nut of our shops. About 120,000 bags, averaging 1½ bushel each, or 150,000 bushels, are annually imported into Great Britain. The import value is about 33s. per bag. They are always kiln-dried when we receive them. This is not the case with the black Spanish, of which only about 12,500 three-bushel bags, or about 37,000 bushels, are imported in the beginning of the season, when their value is about 14s. per bushel. From the Black Sea we receive annually about 68,000 bushels of hazel-nuts, worth 10s. per bushel, with from 500 to 1000 bags of the so-called Jerusalem and Mount Atlas filberts. Of chestnuts from Leghorn, Naples, Spain, France, and Portugal, we receive annually about 20,000 bushels. The trade in walnuts is very uncertain, and probably never exceeds 5000 bushels. Of the curious three-cornered or Brazil nut from Para and Maranham, the importation is also very irregular, varying from 300 to 1000 tons, or 1200 to 4000 bushels per annum. About two millions of cocoa-nuts are also imported. The other kinds of nuts are too irregular in their importations to supply any reliable statistics. The value of all the nuts imported for use as fruit was £510,277 in 1880.

NUTATION is a slight oscillatory movement of the earth's axis, which disturbs the otherwise circular path described by the pole of the earth round that of the ecliptic, known as the 'precession of the equinoxes.' It is produced by the same causes, viz. the attraction of the sun, moon, and planets (the attraction of the last mentioned being so small as to be quite imperceptible) upon the bulging zone about the earth's equator, though in this case it is the moon alone that is the effective agent. It also, for reasons which need not be given here, depends, for the most part, not upon the position of the moon in her orbit, but of the moon's node. If there was no precession of the equinoxes, nutation would appear as a small elliptical motion of the earth's axis, performed in the same time as the moon's nodes take to complete a revolution, the axes of the ellipse being respectively 18"·5 and 13"·7, the longer axis being

directed towards the pole of the ecliptic. But this motion, when combined with the more rapid one of precession, causes the pole of the earth's axis to describe a wavy line round P, the pole of the ecliptic.

The effect of nutation, when referred to the equator and ecliptic, is to produce a periodical change in the obliquity of the ecliptic, and in the velocity of retrogradation of the equinoctial points. It thus gives rise to the distinction of 'apparent'

from 'mean' right ascension and declination, the former involving, and the latter being freed from the fluctuations arising from nutation. This motion is common to all the planets.

NUT-CRACKER (*Nucifraga* or *Caryocatactes*), a genus of birds of the family *Corvidæ*, with a straight conical bill, both mandibles terminating in an obtuse point, and tail nearly square at the end. The form and characters are nearly similar to those of crows, but the habits are rather those of jays, and in some respects indicate an approach to woodpeckers. One species (*N. caryocatactes* or

Nut-cracker (*Nucifraga caryocatactes*).

C. nucifraga) is occasionally seen in Britain, and is not uncommon in many parts of Europe and of Asia, particularly in mountainous regions covered with pines. It is about the size of a jackdaw, but has a longer tail. The plumage is light brown, speckled with white, except on the wings, rump, and tail, which are nearly black. The N. frequents the tops of high pines, and is a shy bird.

NUT-HATCH (*Sitta*), a genus of birds of the family *Certhiada*, having a straight conical or pris-

European Nut-hatch (*Sitta Europæa*).

matic bill, short legs, the hind-toe very strong. They run up and down trees with great agility, moving with equal ease in either direction, and without hopping, so that the motion is rather like that of a mouse than of a bird. They feed on insects, in pursuit of which they examine the crevices, and remove the scales of the bark ; also on seeds, as those of pines, and the kernels of nuts, to obtain which they fasten the nut firmly in some crevice

of bark or other such situation, and peck at it until the shell is broken, so placing themselves that they sway not merely the head, but the whole body, to give force to the stroke. The English name is said to have been originally *Nut-hack*. One species, the EUROPEAN N. (*S. Europæa*), is common in most parts of Europe, and is found in most of the wooded districts of England. Its whole length is about six inches. If taken young, it is easily tamed, and becomes very familiar and amusing; but an old bird caught and put into a cage, is apt to kill itself by violently pecking to force a way out. It soon destroys the wood of a cage.—Other species are found in the East and in North America, where the genus is particularly abundant. Birds nearly allied are found in Australia.

NUTMEG. This well-known and favourite spice is the kernel—mostly consisting of the albumen—of the fruit of several species of *Myristica*. This genus belongs to a natural order of exogens called *Myristicaceæ*, which contains about forty species, all tropical trees or shrubs, natives of Asia, Madagascar, and America. They generally have red juice, or a juice which becomes red on exposure to air. The order is allied to *Lauraceæ*. The leaves are alternate and without stipules. The flowers are unisexual, the perianth generally trifid, the filaments united into a column. The fruit is succulent, yet opens like a capsule by two valves. The seed is nut-like, covered with a lacinated fleshy aril, and has an albumen penetrated by its membranous covering. The species of this order are generally more or less aromatic in all their parts; their juice is styptic and somewhat acrid; the albumen and aril contain both a fixed and an essential oil, and those of some species are used as spices. The genus *Myristica* has the anthers united in a cylindrical

preserved and eaten as a sweetmeat. Within is the nut, enveloped in the curious yellowish-red aril, the *Mace* (q. v.), under which is a thin shining brown shell, slightly grooved by the pressure of the mace, and within is the kernel or nutmeg. Up to 1796, the Dutch being the possessors of the Banda Isles, jealously prevented the N. from being carried in a living state to any other place; but during the conquest and retention of the islands by the British, care was taken to spread the culture of this valuable spice, and plants were sent to Penang, India, and other places, where they are now successfully cultivated; indeed, they have now become established in the West India Islands, and both Jamaica and Trinidad produce excellent nutmegs. Brazil is also found favourable to their culture. The N. is very liable to the attack of a beetle, which is very destructive, and it is a common practice to give them a coating of lime before shipping them to Europe, in order to protect them from its ravages. The Dutch or Batavian nutmegs are nearly always limed, but those from Penang are not, and are consequently of a greater value. The N. yields, by expression, a peculiar yellow fat, called oil of mace, because, from its colour and flavour, it was generally supposed to be derived from mace; and by distillation is obtained an almost colourless essential oil, which has very fully the flavour of the nutmeg. Her own settlements now furnish Great Britain with the greater portion of this spice, but some lots of Batavian also come into the market. The quantity imported may be stated as 300,000 pounds' weight, worth, in round numbers, £70,000.

Nutmegs are chiefly used as a spice; but medicinally they are stimulant and carminative. They possess narcotic properties, and in large doses produce stupefaction and delirium, so that they ought not to be used where affections of the brain exist or are apprehended.

Other species of *Myristica*, besides those already named, yield nutmegs sometimes used, but of very inferior quality.—The fruits of several species of *Lauraceæ* also resemble nutmegs in their aromatic and other properties; as the cotyledons of *Nectandra Puchury*, the Pichurim Beans of Commerce, and the fruit of *Acrodididium camara*, a tree of Guiana, the Camara or Ackawai nutmeg. The clove nutmegs of Madagascar are the fruit of *Agathophyllum aromaticum*, and the Brazilian nutmegs of *Cryptocarya moschata*. All these belong to the order *Lauraceæ*. The Calabash N. is the fruit of *Monodora myristica*, of the natural order *Anonaceæ*.

NUTRIA. See COYPU and RACOONDA.

NUTRITION. The blood which is carried by the capillaries to the several tissues of the body is the source from whence all the organs derive the materials of their growth and development; and it is found that there is direct proportion between the vascularity of any part and the activity of the nutrient operations which take place in it. Thus, in nervous tissue and muscle, in mucous membrane and in skin, a rapid decay and renovation of tissue are constantly going on, and these are parts in which the capillaries are the most abundant; while in cartilage and bone, tendon and ligament, the disintegration of tissue is comparatively slow, and the capillaries are much less abundant. Each elementary cell or particle of a tissue seems to have a sort of gland-like power not only of attracting materials from the blood, but of causing them to assume its structure, and participate in its properties. Thus, from the same common source, nerves form nervous tissue, muscles muscular substance, and even morbid growths, such as cancer, have an assimilating power.

Nutmeg (*Myristica moschata*):

A branch showing fruit, and section of fruit, with nutmeg enclosed.

column, and the cotyledons folded. The species which furnishes the greater part of the nutmegs of commerce is *M. fragrans* or *moschata*; but the long N. (*M. fatua*), from the Banda Isles, is now not uncommon in our markets. The common N.-tree is about 25 feet in height, with oblong leaves, and axillary few-flowered racemes; the fruit is of the size and appearance of a roundish pear, golden yellow in colour when ripe. The fleshy part of the fruit is rather hard, and is of a peculiar consistence, resembling candied fruit; it is often

NUTRITION.

Before entering further into the subject of nutrition, it is necessary to understand how it differs from the allied processes of development and growth. All these processes are the results of the plastic or assimilative force by which living bodies are able to form themselves from dissimilar materials (as when an animal subsists on vegetables, or when a plant grows by appropriating the elements of water, carbonic acid, and ammonia); but they are the results of this force acting under different conditions.

Development is the process by which each tissue or organ of a living body is first formed, or by which one, being already incompletely formed, is so changed in shape and composition, as to be fitted for a function of a higher kind, or finally is advanced to the state in which it exists in the most perfect condition of the species.

Growth, which commonly concurs with development, and continues after it, is properly mere increase of a part by the insertion or superaddition of materials similar to those of which it already consists. In growth, properly so called, no change of form or composition occurs; parts only increase in weight, and usually in size; and if they acquire more power, it is only more power of the same kind as that which they before enjoyed.

Nutrition, on the other hand, is the process by which the various parts are maintained in the same general conditions of form, size, and composition, which they have already by development and growth attained. It is by this process that an adult person in health maintains for a considerable number of years the same general outline of features, and nearly the same size and weight, although during all this time the several tissues of his body are undergoing perpetual decay and renovation. In many parts, this removal and renewal of the particles is evident. In the glands—the Kidneys (q. v.), for example—the cells of which they are mainly composed are being constantly cast off; yet each gland maintains its form and proper composition, because for every cell that is thrown off, a new one is produced. In the epidermis of the skin, a similar process is perpetually going on before our eyes. In the muscles, a similar change may be readily traced, for within certain limits, an increased amount of exercise is directly followed by an increased excretion of the ordinary products of the decomposition of the nitrogenous tissues—viz. urea, carbonic acid, and water. Again, after prolonged mental exertion, there is often a very marked increase in the amount of alkaline phosphates in the urine, which seems to shew that in these cases there is an excessive oxidation of the phosphorus of the brain; and yet, in consequence of the activity of the reparative process, neither the muscles nor the brain diminish in size.

It may be regarded as an established fact in physiology, that every particle of the body is formed for a certain period of existence in the ordinary conditions of active life, at the end of which period, if not previously destroyed by excessive exercise, it is absorbed or dies, and is cast off. (The hair and deciduous or milk teeth afford good illustrations of this law.) The less a part is exercised, the longer its component particles appear to live. Thus, Mr Paget found that, if the general development of the tadpole be retarded by keeping it in a cold, dark place, and if hereby the functions of the blood corpuscles be slowly and imperfectly discharged, the animal will retain its embryonic state for several weeks longer than usual, and the development of the second set of corpuscles will be proportionally postponed, while the individual life of

the corpuscles of the first set will be, by the same time, prolonged.

For the due performance of the function of nutrition, certain conditions are necessary, of which the most important are—1, a right state and composition of the blood, from which the materials of nutrition are derived; 2, a regular and not far distant supply of such blood; 3, a certain influence of the nervous system; and 4, a natural state of the part to be nourished.

1. There must be a certain adaptation peculiar to each individual between the blood and the tissues. Such an adaptation is determined in its first formation, and is maintained in the concurrent development and increase of both blood and tissues. This maintenance of the sameness of the blood is well illustrated by the action of vaccine matter. By the insertion of the most minute portion of the virus into the system, the blood undergoes an alteration which, although it must be inconceivably slight, is maintained for several years; for even very long after a successful vaccination, a second insertion of the virus may have no effect, because the new blood formed after the vaccination continues to be made similar to the blood as altered by the vaccine matter. So, in all probability, are maintained the morbid states of the blood which exist in syphilis and many other chronic diseases; the blood once inoculated, retaining for years the taint which it once received. The power of assimilation which the blood exercises in these cases is exactly comparable with that of maintenance by nutrition in the tissues; and evidence of the adaptation between the blood and the tissues, and of the delicacy of the adjustment by which it is maintained, is afforded by the phenomena of symmetrical diseases (especially of the skin and bones), in which, in consequence of some morbid condition of the blood, a change of structure affects in an exactly similar way the precisely corresponding parts on the two sides of the body, and no other parts of even the same tissue. These phenomena (of which numerous examples are given in two papers by Dr W. Budd and Mr Paget in the 25th volume of the *Medico-chirurgical Transactions*) can only be explained on the assumption—1st, of the complete and peculiar identity in composition in corresponding parts of opposite sides of the body; and 2dly, of so precise and complete an adaptation between the blood and the several parts of each tissue, that a morbid material being present in the blood, may destroy its fitness for the nutrition of one or two portions of a tissue, without affecting its fitness for the maintenance of the other portions of the same tissue. If, then, the blood can be fit for the maintenance of one part, and unfit for the maintenance of another part of the same tissue (as the skin or bone), how precise must be that adaptation of the blood to the whole body, by which in health it is always capable of maintaining all the different parts of the numerous organs and tissues in a state of integrity.

2. The necessity of an adequate supply of appropriate blood in or near the part to be nourished, is shewn in the frequent examples of atrophy of parts to which too little blood is sent, of mortification when the supply of blood is entirely cut off, and of defective nutrition when the blood is stagnant in a part. The blood-vessels themselves take no share in the process, except as the carriers of the nutritive matter; and provided they come so near that the latter may pass by imbibition, it is comparatively unimportant whether they ramify within the substance of the tissue, or (as in the case of the non-vascular tissues, such as the epidermis, cornea, &c.) are distributed only over its surface or border.

3. Numerous cases of various kinds might be

readily adduced to prove that a certain influence of the nervous system is essential to healthy nutrition. Injuries of the spinal cord are not unfrequently followed by mortification of portions of the paralysed parts; and both experiments and clinical cases shew that the repair of injuries takes place less completely in parts paralysed by lesion of the spinal cord than in ordinary cases. Division of the trunk of the trifacial nerve has been followed by incomplete nutrition of the corresponding side of the face, and ulceration of the cornea is a frequent consequence of the operation.

4. The fourth condition is so obvious as to require no special illustration.

For further information on this most important department of physiology, the reader is referred to Sir James Paget's *Surgical Pathology*, or to his lectures on Nutrition, Hypertrophy, and Atrophy; to Kirkes's *Handbook of Physiology* (to which we are indebted for much in this article), Foster's *Textbook of Physiology*, or the works on Physiology by Carpenter, Huxley, Flower, Draper, and Marshall.

NUX VOMICA is the pharmacopoeial name of the seed of *Strychnos Nux Vomica*, or *Poison Nut*. The following are the characters of these seeds, which are imported from the East Indies: 'Nearly circular and flat, about an inch in diameter, umbilicated and slightly convex on one side, externally of an ash-gray colour, thickly covered with short satiny hairs, internally translucent, tough and horny, taste intensely bitter, inodorous.'—*The British Pharmacopœia*, p. 99.

For the genuine characters, see the article STRYCHNOS.—The N. V. tree is a native of Coromandel, Ceylon, and other parts of the East Indies. It is a tree of moderate size, with roundish-oblong, stalked, smooth leaves, and terminal corymbs. The fruit is a globular berry, about as large as a small

Nux Vomica:
Branchlet, Leaves, and Flowers.

orange, one-celled, with a brittle shell, and several seeds lodged in a white gelatinous pulp.—The bark is known as *False Angostura Bark*, having been confounded with Angostura Bark, in consequence of a commercial fraud, about the beginning of the present c.; but its properties are very different, as it is very poisonous.

The seeds contain (in addition to inert matters, such as gum, starch, woody fibre, &c.) three alkaloids closely related to each other, which act as powerful

poisons on the animal frame, and speedily occasion violent tetanic convulsions and death. These alkaloids or bases are named *Strychnia*, *Brucia*, and *Igasuria*, and exist in the seeds in combination with lactic and strychnic (or igasuric) acid. For a good method of obtaining pure strychnia, which is by far the most important of the three bases, the reader is referred to p. 328 of *The British Pharmacopœia*.

Strychnia ($C_{15}H_{17}N_2O_2$) occurs 'in right square octahedrons or prisms, colourless and inodorous, scarcely soluble in water, but easily soluble in boiling rectified spirit, in ether, and in chloroform. Pure sulphuric acid forms with it a colourless solution, which, on the addition of bichromate of potash, acquires an intensely violet hue, speedily passing through red to yellow.'—*Op. cit.* In nitric acid, it ought, if pure, to form a colourless solution; if the solution is reddish, it is a sign that brucia is also present. Strychnia combines with numerous acids, and forms well-marked salts, which are amenable to the same tests as the base itself.

Brucia ($C_{14}H_{15}N_2O_2 + 8 Aq$) is insoluble in ether, but more soluble in water and in strong alcohol than strychnia; and it is the most abundant of the three alkaloids in nux vomica. It acts on the animal economy similarly to, but much less actively than strychnia, from which it may be distinguished not only by its different solubility, but by the red colour which is imparted to it by nitric acid, and which changes to a fine violet on the addition of protochloride of tin. Like strychnia, it forms numerous salts.

Igasuria seems closely to resemble brucia in most respects. Little is known regarding *Igasuric Acid*.

Strychnia, brucia, and igasuria occur not only in nux vomica but in the seeds of *Strychnos ignatii* (St Ignatius's beans), and in the seeds and other parts of several plants of the genus *Strychnos*. The amount of strychnia present in these substances varies from 0.5 to 1.5 per cent.

Nux vomica, according to the experiments of Marcet, acts on vegetables as a poison. His experiments were, however, confined to the haricot bean and the lilac. It is poisonous in a greater or lesser degree to most animals, though larger quantities are required to kill herbivorous than carnivorous animals. Thus, a few grains will kill a dog, but some ounces are required to destroy a horse. It is believed, however, that the bird called *Buceros Rhinoceros* eats the nuts with impunity; and a peculiar kind of *Acarus* lives and thrives in the extract of the nuts. Dr Pereira describes three degrees of the operation of this substance on man. 1. In very small doses, its effects are tonic and diuretic, and often slightly aperient. 2. In larger doses, there is a disordered state of the muscular system; the limbs tremble; a slight rigidity or stiffness is felt when an attempt is made to put the muscles in action; and the patient experiences a difficulty in keeping the erect posture. If the use of the medicine be continued, these effects increase in intensity, and the voluntary muscles are thrown into a convulsed state by very slight causes, as, for example, by inspiring more deeply than usual, or even by turning in bed. It is remarkable that in paralysis the effects are most marked in the paralysed parts. 3. In poisonous doses, the symptoms are tetanus and asphyxia, followed by death. It is difficult to say what is the smallest dose that would prove fatal to an adult. Thirty grains of the powdered nuts, given by mistake to a patient, have destroyed life; and three grains of the extract have proved fatal.

The preparations of nux vomica are the powdered nuts, the extracts, the tincture, and strychnia; the

alkaloid being usually preferable, in consequence of its more constant strength. In various forms of paralysis, especially where there is no apparent lesion of structure, nux vomica is a most successful remedy; although there are cases in which it is positively injurious. It is also of service in various affections of the stomach, such as dyspepsia, gastrodynia, and pyrosis. The average dose of the powder is two or three grains, gradually increased; that of the tincture, 10 or 15 minims; and that of the extract half a grain, gradually increased to two or three grains. See A. S. Taylor's *Principles and Practice of Medical Jurisprudence* (3d ed., Lond. 1883).

NYAM-NYAMS are a widespread and well-marked race in Central Africa, occupying an area lying in the basins of the Upper Nile, Congo, and Shari. They have the Monbutts for neighbours in the east, among the headwaters of the Welle, and westwards they border the Fan country. There are three or more branches of N., slightly differing in appearance, language, and civilisation. But they are readily distinguished by their common characters from any other race. They are probably in the main of negro stock, with some alien mixture, physique and language being fundamentally negroid. One outstanding characteristic of the N. is their pronounced cannibalism in its worst forms; and they are very fierce and savage generally. But they are highly intelligent, very skilful in many branches of industry. The men are frank, brave, and attached and faithful to their wives to a degree unknown amongst any other negro people. Most of our knowledge of them we owe to Schweinfurth.

NYANGWE, a town on the Upper Congo or Lualaba, at the edge of the Manyema country, and some distance below the Lukuga outlet of Lake Tanganyika. N. was the point from which Stanley commenced the descent of the Lualaba in 1876.

NYANZA, VICTORIA, a great fresh-water lake in Central Africa, is the main reservoir of the Upper Nile. Crossed near its northern end by the equator, and bisected by the meridian 33° E., it measures about 230 miles from north to south, and somewhat less from east to west, with an area of over 30,000 square miles (nearly as large as Ireland). This area includes the islands, which are numerous; the larger ones, such as Ukerewe, Sesse, Usuguru, having a considerable population. The surface of the lake is nearly 4000 feet above sea-level, 1400 feet higher than Tanganyika; and though the N. is not so deep as Tanganyika, it is in some places from 500 to 600 feet in depth. The water is good and fresh, in some places of a dirty white colour. The shores are generally low and fertile, and well cultivated, ascending towards hills at no great distance. At the south end of the lake, the Shimiya, the southernmost head-stream of the Nile, enters; and the chief affluent is the Kagera or Kitangule from the west. The Nile (see that article and the map there given), here called Victoria Nile or Somerset River, leaves the lake at its northern extremity by the Ripon Falls, 12 feet high and 400 or 500 feet wide. The lake was discovered in 1858 by Captain Speke (q.v. in SUPP., Vol. X.), and explored by him and Grant, Baker, Stanley, and the missionaries established in Uganda, Mtesa's kingdom, lying on the north-west shore of the lake. Other names for the lake, Nyanza meaning water or lake merely, are Nyanza Ukerewe and Luta Nzige, a name also applied to the *Albert Nyanza* (q.v. in SUPP., Vol. X.), another lake to the west of the Victoria Nyanza.

NYANZA, or NYANJA (apparently the same name as Nyanza), another lake in the interior of Africa. Dr Livingstone discovered it in 1859 by

ascending the river Shiré (q.v.), which conveys the waters of the lake to the Zambesi River at a point near its mouth. Lying 1500 feet above sea-level, the lake is 330 miles long, from 20 to 60 miles broad, and in most parts very deep—in some places over 100 fathoms. Its waters abound with fish. None of the rivers flowing into it are navigable. The country around N. is mountainous, though much of the land surrounding it is low and marshy. For 100 miles the north-eastern shore is bounded by the escarped edge of a plateau 7000 or 10,000 feet high, down which dash numberless waterfalls. The population of its shores, once dense, has been sorely scourged by the slave-trade. Of several mission settlements at or near N., the best known is the Scottish one at Livingstonia, whose founder, Mr E. D. Young, R.N., in 1876 circumnavigated the lake in a steamer, brought in sections up the Shiré River. The Scottish Lakes Company have done much to promote legitimate trade here. Something had previously been known about this lake under the name of the Maravi. See E. D. Young's *N., a Journal of Adventures* (Lond. 1877).

NYĀYA (from the Sanscrit *nī*, into, and *āya*, going, a derivative from *i*, to go; hence literally 'entering,' and figuratively, 'investigating analytically') is the name of the second of the three great systems of ancient Hindu philosophy; and it is apparently so called because it treats analytically, as it were, of the objects of human knowledge, both material and spiritual, distributed by it under different heads or topics; unlike, therefore, the *Vedānta* (q.v.) and *Sāṅkhya* (q.v.), which follow a synthetic method of reasoning, the former of these systems being chiefly concerned in spiritual and divine matters, and the latter in subjects relating to the material world and man. The Nyāya consists, like the two other great systems of Hindu philosophy (see *Mīmāṃsā* and *Sāṅkhya*), of two divisions. The former is called *Nyāya* (proper), and will be exclusively considered in this article; the other is known under the name of *Vaiśeṣika* (q.v.). With the other systems of philosophy, it concurs in promising beatitude, that is, final deliverance of the soul from re-birth or transmigration, to those who acquire truth, which, in the case of the Nyāya, means a thorough knowledge of the principles taught by this particular system.

The topics treated of by the Nyāya are briefly the following: 1. The *pramāṇa*, or instruments of right notion. They are: *a.* Knowledge which has arisen from the contact of a sense with its object; *b.* Inference of three sorts (*ā priori*, *ā posteriori*, and from analogy); *c.* Comparison; and *d.* Knowledge, verbally communicated, which may be knowledge of 'that whereof the matter is seen, and knowledge of 'that whereof the matter is unseen' (revelation). 2. The objects or matters about which the inquiry is concerned (*prameya*). They are: *a.* The *Soul* (*ātman*). It is the site of knowledge or sentiment, different for each individual coexistent person, infinite, eternal, &c. Souls are therefore numerous, but the supreme soul is one; it is demonstrated as the creator of all things. *b.* *Body* (*śarīra*). It is the site of action, of the organs of sensation, and of the sentiments of pain or pleasure. It is composed of parts, a framed substance, not inchoative, and not consisting of the three elements, earth, water, and fire, as some say, nor of four or all the five elements (*viz.* air and ether in addition to the former), as others maintain, but merely earthy. *c.* *Organs of sensation* (*indriya*); from the elements, earth, water, light, air, and ether, they are smell, taste, sight, touch, and hearing. *d.* *Their objects* (*artha*). They are the qualities of earth, &c.—*viz.* odour, savour, colour, tangibility, and sound. *e.* *Understanding* (*buddhi*),

or apprehension (*upalabdhī*), or conception (*jñāna*), terms which are used synonymously. It is not eternal, as the Sāṅkhya maintains, but transitory. *f. The organ of imagination and volition (manas)*. Its property is the not giving rise simultaneously to more notions than one. *g. Activity (pravṛtti)*, or that which originates the utterances of the voice, the cognitions of the understanding, and the gestures of the body. It is therefore oral, mental, or corporeal, and the reason of all worldly proceedings. *h. Faults or failings (doṣha)*, which cause activity—viz. affection, aversion, and bewilderment. *i. Transmigration (pretyabhāva)*, literally, the becoming born after having died), or the regeneration of the soul, which commences with one's first birth, and ends only with final emancipation. It does not belong to the body, because the latter is different in successive births, but to the soul, because it is eternal. *k. Fruit or retribution (phala)*, or that which accrues from activity and failings. It is the consciousness of pleasure or of pain. *l. Pain (duḥkha)*, or that which has the characteristic mark of causing vexation. It is defined as 'the occurrence of birth,' or the originating of 'body,' since body is associated with various kinds of distress. Pleasure is not denied to exist, but, according to the Nyāya, it deserves little consideration, since it is ever closely connected with pain. *m. Absolute deliverance or emancipation (apavarga)*. It is annihilation of pain, or absolute cessation of one's troubles once for all.

After (1) 'instruments of right notion,' and (2) 'the objects of inquiry,' the Nyāya proceeds to the investigation of the following topics.

3. *Doubt (saṃśaya)*. It arises from unsteadiness in the recognition or non-recognition of some mark, which, if we were sure of its presence or absence, would determine the subject to be so or so, or not to be so or so; but it may also arise from conflicting testimony. 4. *Motive (prayojana)*, or that by which a person is moved to action. 5. *A familiar case (dr̥ishānta)*, or that in regard to which a man of an ordinary and a man of a superior intellect entertain the same opinion. 6. *Tenet or dogma (siddhānta)*. It is either 'a tenet of all schools,' i. e. universally acknowledged, or 'a tenet peculiar to some school,' i. e. partially acknowledged; or 'a hypothetical dogma,' i. e. one which rests on the supposed truth of another dogma; or 'an implied dogma,' i. e. one the correctness of which is not expressly proved, but tacitly admitted by the Nyāya. 7. The different members (*avayava*) of a regular argument or syllogism (*nyāya*). 8. *Confutation or reduction to absurdity (tarka)*. It consists in directing a person who does not apprehend the force of the argument as first presented to him, to look at it from an opposite point of view. 9. *Ascertainment (nirṇaya)*. It is the determination of a question by hearing both what is to be said for and against it, after having been in doubt. The three next topics relate to the topic of controversy, viz. 10. *Discussion (vāda)*, which is defined as consisting in the defending by proofs on the part of the one disputant, and the controverting it by objections on the part of the other, without discordance in respect of the principles on which the conclusion is to depend; it is, in short, an honest sort of discussion, such, for instance, as takes place between a preceptor and his pupil, and where the debate is conducted without ambition of victory. 11. *Wrangling (jalpa)*, consisting in the defence or attack of a proposition by means of tricks, futilities, and such like means; it is therefore a kind of discussion where the disputants are merely desirous of victory, instead of being desirous of truth. 12. *Cavilling*

(*vitandā*), when a man does not attempt to establish the opposite side of the question, but confines himself to carping disingenuously at the arguments of the other party. 13. *Fallacies*, or semblances of reasons (*hetvābhāsa*), five sorts of which are distinguished, viz. the erratic, the contradictory, the equally available on both sides, that which, standing itself in the need of proof, does not differ from that which is to be proved, and that which is adduced when the time is not that when it might have availed. 14. *Tricks*, or unfairness in disputation (*chhala*), or the opposing of a proposition by means of assuming a different sense from that which the objecter well knows the propounder intended to convey by his terms. It is distinguished as verbal misconstruing of what is ambiguous, as perverting, in a literal sense, what is said in a metaphorical one, and as generalising what is particular. 15. *Futile objections (jāti)*, of which twenty-four sorts are enumerated; and, 16. Failure in argument or reason of defeat (*nigraha-sādhana*), of which twenty-two distinctions are specified.

The great prominence given by the Nyāya to the method, by means of which truth might be ascertained, has sometimes misled European writers into the belief, that it is merely a system of formal logic, not engaged in metaphysical investigations. But though the foregoing enumeration of the topics treated by it could only touch upon the main points which form the subject-matter of the Nyāya, it will sufficiently shew that the Nyāya intended to be a complete system of philosophical investigation; and some questions, such as the nature of intellect, articulated sound, &c., or those of genus, variety, and individual, it has dealt with in a masterly manner, well deserving the notice of western speculation. That the atomistic theory has been devolved from it, will be seen under the article *VAISĒSHIKA*. On account of the prominent position, however, which the method of discussion holds in this system, and the frequent allusion made by European writers to a Hindu syllogism, it will be expedient to explain how the Nyāya defines the 'different members of a syllogism' under its seventh topic. A regular argument consists, according to it, of five members—viz. *a.* the proposition (*pratīṇḍa*), or the declaration of what is to be established; *b.* the reason (*hetu*), or 'the means for the establishing of what is to be established'; *c.* the example (*udāharaṇa*), i. e. some familiar case illustrating the fact to be established, or inversely, some familiar case illustrating the impossibility of the contrary fact; *d.* the application (*upanaya*), or 're-statement of that in respect of which something is to be established'; and *e.* the conclusion (*nigamana*), or 'the re-stating of the proposition because of the mention of the reason.' An instance of such a syllogism would run accordingly thus: *a.* This hill is fiery, *b.* for it smokes, *c.* as a culinary hearth, or (inversely) not as a lake, from which vapour is seen arising, vapour not being smoke, because a lake is invariably devoid of fire; *d.* accordingly, the hill is smoking; *e.* therefore, it is fiery.

The founder of the Nyāya system is reputed under the name of *Gotama*, or, as it also occurs, *Gautama* (which would mean a descendant of Gotama). There is, however, nothing as yet known as to the history of this personage or the time when he lived, though it is probable that the work attributed to him is, in its present shape, later than the work of the great grammarian Pāṇini. It consists of five books or *Adhyāyas*, each divided into two 'days,' or diurnal lessons, which are again subdivided into sections or topics, each of which contains several aphorisms, or *Sūtras*. See *SŪTRA*. Like the text-books of other sciences among the

Hindus, it has been explained or annotated by a triple set of commentaries, which, in their turn, have become the source of more popular or elementary treatises.—The Sanscrit text of the *Sûtras* of Gotama, with a commentary by *Viśwanātha*, has been edited at Calcutta (1828); and the first four books, and part of the fifth, of the text, with an English version, an English commentary, and extracts from the Sanscrit commentary of *Viśwanātha*, by the late Dr J. R. Ballantyne (Allahabad, 1850—1854). This excellent English version and commentary, and the celebrated *Essay on the Nyāya*, by H. T. Colebrooke (*Transactions of the Royal Asiatic Society*, vol. i. London, 1827; and reprinted in the *Miscellaneous Essays*, vol. i. London, 1837), are the best guide for the European student who, without a knowledge of Sanscrit, would wish to familiarise himself with the Nyāya system.

NYCTAGINACEÆ, a natural order of exogenous plants, consisting partly of herbaceous plants, both annual and perennial, and partly of shrubs and trees. Lindley ranks them in his *Chenopod. Alliance*. The flowers are either clustered or solitary, and either the cluster or the flower often has an involucre, which is often gaily coloured. The perianth is tubular, plaited in bud, coloured; the limb entire or toothed, deciduous. The stamens are equal in number to the lobes of the perianth. The ovary is superior, with one ovule, and one style. The fruit is a thin *caryopsis*, enclosed within the enlarged and indurated base of the perianth.—There are about 100 known species, natives of warm countries. Some have flowers of considerable beauty, as those of the genus *Mirabilis*, known in our gardens as *Marvel of Peru*, one of which, *M. Jalapa*, was at one time erroneously supposed to produce jalap. The roots of many are fleshy, purgative, and emetic. Those of *Boerhaavia paniculata* are used instead of ipecacuanha both in Guiana and in Java.

NYCTERIBIA, an extremely curious genus of insects, ranked in the order *Diptera*, although very different from most of that order, and having neither wings nor balancers. Its nearest alliance is with *Hippoboscida* (see FOREST FLY and SHEEP TICK), which it resembles particularly in parasitic habits, and in the retention of the eggs within the abdomen of the female, until they have not only been hatched, but have passed from the larva into the pupa state. The form, however, is so spider-like, that these insects were at first ranked among the *Arachnida*. The few species known are all parasitic on bats, on which they run about with great activity. The head is very small, curiously affixed to the back of the thorax, and when the creature sucks the blood of the bat, upon which it lives, it places itself in a reversed position.

NYKERK, or NIEUWKERK, on the Veluwe, is a very flourishing and well-built town, near the Zuider Zee, in the province of Gelderland, Netherlands, 25 miles north-west of Arnheim. Pop. 8000. It has a good harbour, which is connected with the sea by a wide canal of $1\frac{1}{2}$ miles in length. In the neighbourhood are fine rich meadow-pastures and lands suited for all kinds of grain, tobacco, potatoes, &c. Tobacco is extensively grown; many cattle are raised; and a brisk trade carried on both with the surrounding country and Amsterdam, the market to which the cattle, tobacco, dairy, and other agricultural produce, together with much firewood, are sent. N. has a handsome Reformed church, a Roman Catholic chapel, a synagogue, orphan-house, and good schools. There are several manufactures carried on, which also give employment to the people. In Netherlands church history, N. is famed as the place where a great religious move-

ment began at the middle of last century. The history of the movement, which spread throughout the land, contains all the marks of the later revivals in America, Scotland, and Ireland. See Ypey and Dermout's *Geschiedenis der Nederd. Her. Kerk*, vol. iv.

NYKÖPING, a seaport of Sweden, pleasantly situated on the Baltic, in lat. $58^{\circ} 45' N.$, long. $17^{\circ} E.$, about 60 miles south-west of Stockholm. It comprises among its manufacturing products cotton goods, stockings, tobacco, &c., and has good shipyards, mills, and manufactories for machinery, while in the vicinity of the town are extensive paper-mills. The ruined old castle of N., nearly destroyed by fire in 1665, and which ranked in point of strength next to those of Stockholm and Calmar, has experienced many eventful vicissitudes of fortune. King Valdemar of Sweden, after his dethronement in 1288, was imprisoned here till his death in 1302; but the most tragic incident connected with N. Castle was the horrible death within its walls of the Dukes Eric and Valdemar, who, after being entrapped by their pusillanimous brother, King Birger, in 1317, were left to perish of hunger in a dungeon, the keys of which the king threw into the sea before he left the castle. The horror of this deed roused the indignation of the people, who seized upon the castle, sacked it, and demolished its keep and donjons. In 1719, the town was taken and dismantled by the Russians; and since then it has ceased to be the scene of any events of historical interest. It is noted for the pure Swedish spoken by its inhabitants. Pop. (1880) 4813.

NYL-GHAU (*Antelope picta*, or *Portax tragocamelus*), a species of antelope, with somewhat ox-like head and body, but with long slender limbs, and of great activity and fleetness. It is one of the largest of antelopes, and is more than four feet high at the shoulder. The horns of the male are about as long as the ears, smooth, black, pointed, slightly curved forwards. The female has

Nyl-Ghau (*Antelope picta*).

no horns. The neck is deep and compressed, not rounded as in most of the antelopes. A slight mane runs along the neck and part of the back, and the breast is adorned with a long hanging tuft of hair. The back is almost elevated into a hump between the shoulders. The N. inhabits the dense forests of India and Persia, where it has long been regarded as one of the noblest kinds of game. It is often taken, like other large animals, by the enclosing of

a large space with nets, and by great numbers of people. It is a spirited animal, and dangerous to a rash assailant. It is capable of domestication, but is said to manifest an irritable and capricious temper.

NYMPHÆACEÆ, a natural order of exogenous plants, growing in lakes, ponds, ditches, and slow rivers, where their fleshy rootstocks are prostrate in the mud at the bottom; and their large, long-stalked, heart-shaped, or peltate leaves float on the surface of the water. Their flowers also either float, or are raised on their stalks a little above the water. The flowers are large, and often very beautiful and fragrant. There are usually four sepals, and numerous petals and stamens, often passing gradually into one another. The ovary is many-celled, with radiating stigmas, and very numerous ovules, and is more or less surrounded by a large fleshy disc. The seeds have a farinaceous albumen. More than fifty species are known, mostly natives of warm and temperate regions. The rootstocks of some of them are used as food, and the seeds of many.—See **WATER-LILY**, **LOTUS**, **VICTORIA**, and **EURYALE**.—Very nearly allied to *N.* are *Nelumbiaceæ*. See **NELUMBO**.

NYMPHS, in Classic Mythology, female divinities of inferior rank, inhabiting the sea, streams, groves, meadows and pastures, grottoes, fountains, hills, glens, trees, &c. Among the *N.*, different classes were distinguished, particularly the *Oceanides*,

daughters of Oceanus (*N.* of the great ocean which flows around the earth), the *Nereids*, daughters of Nereus (*N.* of the inner depths of the sea, or of the Inner Sea—the Mediterranean), *Potameides* (River *N.*), *Naiads* (*N.* of fountains, lakes, brooks, wells), *Oreades* (Mountain *N.*), *Dryads* or *Hamadryads* (Forest *N.*, who were believed to die with the trees in which they dwelt). They were the goddesses of fertilising moisture, and were represented as taking an interest in the nourishment and growth of infants, and as being addicted to the chase (companions of the divine huntress Diana), to female occupations, and to dancing. They are among the most beautiful conceptions of the plastic and reverent (if credulous) fancy of the ancient Greeks, who, in the various phenomena of nature—the rush of sea-waves, the bubble of brooks, the play of sunbeams, the rustle of leaves, and the silence of caves—felt, with a poetic vividness that our modern science will hardly permit us to realise, the presence of unseen joyous powers.

NY'SSA. See **TUPELO**.

NYSTADT, a town of Finland, on the eastern coast of the Gulf of Bothnia, 60 miles south of Björneborg. Here, in 1721, a treaty was agreed to, between Russia and Sweden, by virtue of which all the conquests of Peter the Great along the coasts of the Gulf of Finland were annexed to Russia. Pop. (1880) 3837.

O

THE fifteenth letter in the English and in most western alphabets, is one of the five simple vowel signs of the English language. As the language is at present pronounced, it stands for at least four distinct sounds, heard in the words *note*, *nōr*, (*nōt*), *more*, *son*. The primary and simple sound of O is that heard long in *nōr*, and short in *nōt*, *thp*. The sound given to it in such words as *note*, *go*, is really a diphthong—a

long o terminating in a slight u or oo sound (O^u). The corresponding letter in the Hebrew and Phœnician Alphabet (q. v.) was called Ayn, i. e., 'eye'; and accordingly the primitive form of the Phœnician letter was a rough picture of an eye, which naturally became a circle with a dot in the centre—still to be seen in some ancient inscriptions—and then a simple circle.

O', a prefix in many Irish family names, serves to form a patronymic, like *Mac* in Gaelic names; as O'Brien, a descendant of Brien. By some, it is considered to be derived from *o'*; but it is more likely from Ir. *ua*, Gael. *ogha*, a grandson. In the Lowland Scottish, the word *oe* is used for grandson, and in some localities for nephew.

OAHU, one of the Sandwich Islands (q. v.).

OAJA'CO, OAXACA, or GUAXACA, a city of Mexico, capital of a state of the same name, stands on the river Rio Verde, 210 miles south-south-east of Mexico. It covers an area 2 miles in length by 1½ in breadth, is well built, with open streets, interspersed with plantations, on which the cochineal insect feeds, and has about 25,000 inhabitants. Silk, cotton, sugar, and chocolate are manufactured.

OAK (*Quercus*), a genus of trees and shrubs of the natural order *Cupulifera*, having a three-celled ovary, and a round (not angular) nut—which is called an *acorn*—placed in a scaly truncated cup, the lower part of it invested by the cup. The species are very numerous, natives of temperate and tropical countries. A few species are found in Europe. North America produces many; and many are natives of mountainous regions in the torrid zone; some are found at low elevations in the valleys of the Himalaya, some even at the level of the sea in the Malay peninsula and Indian islands. But in the peninsula of India and in Ceylon, none are found; and none in tropical Africa, in Australia, or in South America. The oaks have alternate simple leaves; which are entire in some, but in the greater number variously lobed and sinuated or cut; evergreen in some, but more generally deciduous. Many of them are trees of great size, famous for the strength and durability of their timber, as well as for the majesty of their appearance, and their great longevity.—Throughout all parts of Europe, except the extreme north, two species are found, or varieties of one species, the COMMON OAK (*Q. robur*); one (*Q. pedunculata*) having the acorns on longish stalks,

the other (*Q. sessiliflora*) having them almost without stalks. Other differences have been pointed out; but they are regarded by some of the most eminent and careful botanists as merely accidental, and not coincident with these; while, as to the length of the fruit-stalks, every intermediate gradation occurs. Both varieties occur in Britain, the first being the most prevalent, as it is generally in the north of Europe; the second being more abundant in more southern countries. The short-stalked oak is sometimes called DORMAST OAK in England. It has been much disputed which is entitled to be considered the true British oak; and much alarm has occasionally been expressed lest new plantations should be made of the wrong kind; whilst the most contradictory statements have been made as to the comparative value and characters of the timber. The oak succeeds best in loamy soils, and especially in those that are somewhat calcareous. It cannot endure stagnant water. It succeeds well on soils too poor for ash or elm; but depends much on the depth of the soil, its roots penetrating more deeply than those of most other trees. Noble specimens of oak trees, and some of them historically celebrated, exist in almost all parts of Britain; but are much more frequent in England than in Scotland. The former existence of great oak forests is attested by the huge trunks often found in bogs. The oak attains a height of from 50 to 100 or even 150 or 180 feet; the trunk being four, six, or even eight feet in diameter. It sometimes grows tall and stately, but often rather exhibits great thickness of bole and magnitude of branches. It reaches its greatest magnitude in periods varying from 120 to 400 years, but lives to the age of 600, or even 1000. The timber is very solid, durable, peculiarly unsusceptible of the influence of moisture, and therefore eminently adapted for ship-building. It is also employed in carpentry, mill-work, &c.—The bark abounds in tannin; it also contains a peculiar bitter principle called *Quercine*, and is used in medicine, chiefly in gargles, &c., on account of its astringency, sometimes also as a tonic; it is used along with gall-nuts in the manufacture of ink; but most of all for tanning (see BARK), and on this account the oak is often planted as copse-wood (see CORSE) in situations where it cannot be expected to attain to great size as a tree. The timber of copse oak is excellent firewood. The oak is particularly fitted for copse-wood, by the readiness with which it springs again from the stools after it has been cut.—Acorns are very nourishing food for swine, and in times of scarcity have been often used for human food, as, indeed, they commonly are in some very poor countries, either alone or mixed with meal. The bitterness which makes them disagreeable is said to be in part removed by burying them for a time in the earth. The acorns of some trees are also much less bitter than others, and oaks of the common species occur which produce acorns as sweet as chestnuts. Other varieties of the common oak are assiduously propagated by nurserymen as

curious and ornamental, particularly one with pendulous branchlets (the *Weeping Oak*), and one with branches growing up close to the stem, as in some kinds of poplar. Among the Greeks and Romans, the oak was sacred to Zeus or Jupiter; and it has been connected with the religious observances of many nations, as of the ancient Celts and Germans. —The **TURKEY OAK** or **ADRIATIC OAK** (*Q. cerris*), now very frequently planted in Britain, is a large and valuable tree, very common in the south-east of Europe, and in some parts of Asia. The timber is imported in considerable quantity into Britain for ship-building and other purposes. The leaves differ from those of the common oak in their acute lobes, and the cups of the acorns are *moosey*, i.e., have long, loose, acute scales. Similar to this, in both these respects, are the **AUSTRIAN OAK** (*Q. Austriaca*), abundant near Vienna, and the **SPANISH OAK** (*Q. Hispanica*). —The **CORK OAK** or **CORK-TREE** (*Q. suber*) is noticed in the article **CORK**; the **HOLM OAK** or **EVERGREEN OAK** (*Q. ilex*), another of the species found in the south of Europe, in the article **ILEX**. —Of the North American oaks, some are very valuable as timber trees. Perhaps the most important is the **WHITE OAK** or **QUEBEC OAK** (*Q. alba*), a large tree, the leaves of which have a few rounded lobes. It is found from the Gulf of Mexico to Canada; and in some places forms the chief part of the forest. The timber is less compact than that of the British oak; that of young trees is very elastic. —The **OVERCUP OAK** (*Q. lyrata*), a majestic tree, highly esteemed for its timber, and having its acorns almost covered by their globular cup, grows chiefly in lands liable to inundation in the Southern States. —The **CHESTNUT-LEAVED WHITE OAK** (*Q. prinus*) is also a much-esteemed timber tree of the Southern States. —The **SWAMP WHITE OAK** (*Q. bicolor*), a closely allied species, extends further north. —The **LIVE OAK** (*Q. vivens*), an evergreen species, with entire leathery leaves, is regarded as a tree of the first importance in the United States, from the excellence of its timber and its value for ship-building, so that efforts have been made by the government to protect it and to promote the planting of its acorns. Yet it is not a very large tree, being seldom more than forty-five feet in height, with a trunk of two feet in diameter. It grows on the coasts of the Gulf of Mexico, and as far north as Virginia. It once abounded on the Sea Islands, now so celebrated for their cotton. —The **RED OAK** (*Q. rubra*), a large tree, with sinuated and lobed leaves, the lobes toothed and bristle-pointed, yields great part of the *Red Oak Staves* exported from Canada and the north of the United States to the West Indies; but *Red Oak Staves* are also produced in the Middle and Southern States by the **SCARLET OAK** (*Q. coccinea*), a very similar species, by the **BLACK OAK** or **QUERCITRON OAK** (*Q. tinctoria*), another species with the lobes of the leaves bristle-pointed, better known for the dye-stuff which its bark yields (see **QUERCITRON**), and by the **Willow Oak** (*Q. phellos*), a large tree with lanceolate leaves and a willow-like aspect. The timber of all these species is of very inferior quality. These are the American oaks of greatest economical and commercial importance, but there are numerous other species, some of them trees, some mere shrubs, of which some grow on poor soils, and cover them in compact masses; resembling in this a single European species (*Q. viminalis*), a native of the Vosges, 6–8 feet high, with slender tough branches, which makes excellent hedges. —The **BLACK JACK** (*Q. nigra*) is an American oak, chiefly notable for the abundance in which it grows on some of the poorest soils. It is a small tree, and its timber of little value. The bark is black. —Some of the Nepanese oaks are large and

valuable trees, as are some of those of China and Japan, of Java, of Mexico, &c. The oaks of Java and the other Indian islands have generally the leaves quite entire. —The bark of most of the species of oak is capable of being used for tanning, and is used in different countries. The cups and acorns of the **VALONIA OAK** (*Q. Egilops*) are exported from the Morea and other parts of the Levant, in great quantities, for this purpose, under the name of *Valonia*. See **LEATHER**. The tree resembles the Turkey Oak, and has very large hemispherical mossy cups. The cups are said to contain more tannin than any other vegetable substance. —Galls (*q. v.*) or Gall-nuts are in great part obtained from the oak therefore called the **GALL-OAK** (*Q. infectoria*), a scrubby bush, a native of Asia Minor, with bluntly serrated, ovate-oblong leaves. —The **KERMES OAK** (*Q. coccifera*), on the leaves of which the Kermes (*q. v.*) insect is found, is a low bush, with evergreen spinous leaves, much resembling a holly, a native of the south-east of Europe. —Of oaks with sweet and edible acorns, may be mentioned the **BALLOTS OAK** (*Q. Ballota* or *Gramuntia*), an evergreen with round spiny-toothed leaves, a native of the north of Africa, the acorns of which are regularly brought to market in Algeria and in Spain, and are long and cylindrical; the **Italian Oak** (*Q. Esculus*), closely allied to the common oak; and the **DWARF CHESTNUT OAK** (*Q. chinquapin* or *prinosides*) of North America, a small shrubby species, which has been specially recommended to cultivation on this account. Other North American species, and some of the Himalayan species, also produce edible acorns. From the acorns of some species, oil is made in considerable quantity in different parts of the world, and is used in cookery. —The leaves of the **Manna Oak** (*Q. mannifera*) — a native of the mountains of Kurdistan, having oblong, blunt-lobed leaves — secrete in hot weather a kind of manna, a sweet mucilaginous substance, which is made into sweetmeats, and very highly esteemed.

The name Oak is sometimes popularly applied to timber trees of very different genera. Thus, **AFRICAN OAK** is another name of African Teak. See **TEAK**. Some of the species of *Casuarina* (*q. v.*) are called Oak in Australia. The **STONE OAK** (*Lithocarpus Javanensis*) of Java, so named from the extreme hardness of its timber, is a tree of the same family with the true oaks.

OAK BEAUTY (*Biston prodromaria*), a moth of the family *Geometridæ*, a native of England, about an inch and a half or two inches in expanse of wings; the upper wings with two brown curved bands, margined with black, the lower wings with one brown band. The caterpillar feeds on the oak.

OA'KHAM, the county-town of Rutlandshire, in the vale of Catmos, 25 miles W.N.W. of Peterborough. The castle is now in ruins, with the exception of the portion used as the county-hall. The church, restored in 1858, is an edifice in the perpendicular style, and has a fine tower and spire. The Free Grammar-school, with an endowment of about £700 a year, was founded in 1581. Pop. (1881) 3227.

OAKLAND, a city of California, U.S.A., on a beautiful site on the east shore of San Francisco Bay, here 7 miles wide. It is a favourite residence of business men from San Francisco, just opposite. Pop. (1870) 10,500; (1880) 34,556.

OAK'UM a tangled mass of tarred hempen fibres, is made from old rope by untwisting the strands and rubbing the fibres free from each other. Its principal use is in Caulking (*q. v.*) the seams between planks, the space round rivets, bolts, &c., for the purpose of preventing water from penetrating.

OANNES, the name of a Babylonian god, who, in the first year of the foundation of Babylon, is said to have come out of the Persian Gulf, or the old Erythraean Sea, adjoining Babylon. He is described as having the head and body of a fish, to which were added a human head and feet under the fish's head and at the tail. He lived amongst men during the daytime, without, however, taking any

Oannes.

food, and retired at sunset to the sea, from which he had emerged. O. had a human voice, and instructed men in the use of letters, and in all the principal arts and sciences of civilisation, which he communicated to them. Such is the account of him preserved by Berossus and Apollodorus. Five such monsters are said to have come out of the Persian Gulf; one, called Anedotos or Idotian, in the reign of Amemon, the fourth king of Babylon; another in that of the fifth king; and the last, called Odacon (or Ho Dagon), apparently the Phœnician Dagon, under the sixth. Many figures of O., resembling that of a Triton, having the upper part of a man, and the lower of a fish, or as a man covered with a fish's body, have been found in the sculptures of Kouyunjik and Khorsabad, as well as on many cylinders and gems. O. is supposed to have symbolised the conquest of Babylonia by a more civilised nation coming in ships to the mouth of the Euphrates; but he is apparently a water-god, resembling in type and character the Phœnician Dagon, and the Greek Proteus and Triton.

Helladius, *Apud Phot. Cod.* 279, pp. 535, 34; Richter, *De Beross.* Cory, *Anc. Fragm.* p. 30; 1 Sam. v. 4; Bunsen, *Egypt's Place*, vol. i. p. 706; Layard, *Nineveh*, p. 343.

OAR, a wooden instrument by which a person sitting in a boat propels it through the water. The form found in practice to combine greatest power with lightness, is that shewn in the figure. From *a* to *b* is the blade of the oar, thin and nearly flat, though occasionally somewhat curved, so as to present a concave surface to the water; from *b* to *d* is round or square, gradually thickening towards *d*, that the part *ce* may nearly balance the part *ac*. At *de* is the handle, which is grasped by one or both hands. The oar rests at *c* on the row-lock, and in many cases some device is resorted to, to retain the oar from slipping outwards. In the Thames, a leathern stop, called a button, is used; sometimes a pin in the gunwale of the boat passes through the oar (but this weakens the oar, and precludes feathering); at other times, the oar is fastened to the pin by a leathern thong. The action of an oar in moving a boat is that of a lever, the rower's hand being the power, the water the fulcrum, against which the oar presses, and the row-lock the point at which the opposition caused by the weight of the boat and its cargo is felt. Feathering an oar consists in turning it, immediately on leaving the water, so that the flat blade of the oar is horizontal, and in preserving this position until just before the fresh dip, when of course the

vertical position must be resumed. Feathering diminishes the resistance offered by air, wind, and small waves; it also adds greatly to the beauty and grace of rowing.

The best oars are of Norway fir, though some are made of ash and beech.

O'ASES, certain cultivated spots in the Libyan desert (called also *Auasis*, *Ouasis*, or *Hoasis*) which produce vegetation, owing to the presence of springs issuing from the ground. The principal oases are those lying to the west of Egypt, a few days' journey from the Nile, and known to the ancients by the name of the Greater and Lesser Oases, and that of Ammon. It is supposed that they were known to the Egyptians during the 12th dynasty under the name of *Suten-Khem*, but no evidence of their occupation by the Egyptians earlier than Darius has been found *in situ*. By some of the ancients they were called the Islands of the Blessed, or compared to the spots on a panther's skin. Their name is supposed to be the Coptic *Ouahé* (Inhabited Place). They are first mentioned by Herodotus in his account of the destruction of the army of Cambyses by the storm of sand, or simoom. Equally celebrated is the visit of Alexander the Great to the oasis, which he successfully accomplished after the conquest of Egypt, and passed through the desert a nine days' journey before he reached the Temple of Ammon, the priests of which declared him the son of that god, and the future conqueror of the entire world. Herodotus describes that of El Wah, or the Oasis Magna of the Romans, which contained the oracle of Ammon, and which lies seven days' journey west of Thebes. It appears to have been anciently frequented by caravans going to the Pillars of Hercules. Strabo mentions three oases: the first seven days' journey west of Abydos; the second, west of the Lake Moeris; the third, near the oracle of Ammon. Pliny mentions two oases; so does Ptolemy, who calls them the Lesser and Greater. Under the Roman empire, they were used for temporary banishment of criminals of state, and the poet Juvenal was sent there. Olympiodorus, a native of the Thebaid, gives a glowing description of them in the days of Theodosius the Younger. Under the Byzantine emperors,

Temple of Jupiter Ammon—Oasis of Siwah.
(From Hoskin's *Visit to the Great Oasis*.)

the emperors banished there the heads of the Catholic party, at the instigation of the Arians, in the 4th c., and Athanasius himself is supposed

to have taken refuge in them. In the 5th c., Nestorius, the Bishop of Constantinople, was banished there. He was rescued by an excursion of the Blemyes, but expired soon after his arrival at the Nile. The oases were then a place of desolation and horror, occasionally plundered by Bednins. They fell, 943 A.D., into the power of the Arabs, after having been held by the Egyptian monarchs and their successors till that period; and they are described by Edriai (1150 A.D.) as uninhabited; by Abulfeda (1240 A.D.) and by Leo Africanus (1513 A.D.), as inhabited and cultivated, and quite independent, having three fortresses. The first modern traveller who visited them is supposed to have been Poncet (1698 A.D.). Subsequently, in 1792, Browne discovered the oasis of Ammon at El Siwah; and it was visited in 1798 by Hornemann, and in 1819 by Caillaud. It lies in 29° 12' 20" N. lat., and 26° 6' 9" E. long. Drovetti and Minutoli also visited the same spot.

These oases are now held by Muggrebi Arabs, a powerful race in the Desert, capable of raising 30,000 men, who supply camels and guides to travellers. The principal oases are: 1. El Khargeh, or the Oasis Magna, the Greater Oasis of Ptolemy; 2. El Kasr, or Oasis Parva, the Lesser Oasis; 3. Siwah, or the Oasis of Ammon, the most northerly; 4. The Western Oasis, or Dakkel, mentioned by Olympiodorus, and visited by Sir Archibald Edmonstone in 1819, and Rohlfs in 1874. Of El Khargeh, full particulars have been given by M. Hoskins, who discovered it lying about 125 miles west of the Nile, having a stream of water rising near the village of Genah, on the north-west of the oasis, and lost in the sand. It is bounded on the east by Hagel-bel-Badah. North of El Gem lies the metropolis, El Khargeh, which consists of a series of covered streets and open bazaars. The temple lies two hours' journey from it, in a fine situation; the *sekos* has a vestibule of 600 feet, with pylons, or gateways, the first of which has a decree in Greek, dated in the reign of Galba (68 A.D.), against forcing persons to farm the revenue, preventing imprisonment for debt, preserving the dowries of women, and limiting the office of strategos for three years. The temple has other decrees preventing the officers of government from smuggling. It has an avenue of sphinxes and three pylons; on the third, Darius is represented offering to Amen Ra, Osiris, and Isis; while Nekht-her-hebi (Nectabes) continued the ornaments of the temple about 414–340 B.C. The *sekos* is 140 feet long, and represents Darius offering to Amen Ra, or Khnumis, the ram-headed god, and Osiris; while in the accompanying scenes are seen Anta, or Anaitis, Raspu, or Reseph. In the vicinity is a magnificent necropolis of 150 sepulchres, of a late period, with Doric and Corinthian capitals. There are several temples at other spots of the oases. 2. El Kasr, the Oasis Parva, lies four or five days' journey south-east of Siwah, called the Wah-el-Bahnasa, or Wah-el-Menesheh, contains no monuments older than the Roman, consisting of a triumphal arch, subterranean and other aqueducts, several hot springs, a necropolis, and Christian church. This oasis was first conquered by the Arabs; and in its vicinity is another oasis called Wady Zerzoora, with others adjoining, of inferior interest. 3. Siwah, or the Oasis of Ammon—one of the first discovered, and repeatedly visited, has, unfortunately, not been seen by any one acquainted with hieroglyphics—lies west of the Natron Lakes. It would appear from Minutoli that the temple was built by Nekht-her-hebi, or Nectabes I., in honour of the god Khnum, Ammon Khnumis or Chnebis, who, as the deity of water, presided over the water from which the oasis

originated. The oasis is nine miles broad and two long, contains El Garah Gharmy, and Menchyeh, has a population of about 8000 inhabitants, possesses date and other trees, grows cereals, and has sulphurous springs, a salt lake at Arachieh, and many ruined temples, a necropolis, and other remains. The oracle of Ammon is supposed to have been at a place called Om-Beydah, or the temple of Nekht-her-hebi. From this, it would seem that the oasis did not fall into the power of Egypt till about the 5th c. B.C. The celebrated Fountain of the Sun is at Siwah Shargieh. It is 30 paces long, 20 broad, six fathoms deep, with bubbles constantly rising to the surface, steaming in the morning, and warmer at night. Close to it are the remains of the sanctuary of Ammon. 4. El Dakkel, or the Western Oasis, lies about 78 miles south-west of Siout. The principal ruin at Dar-el-Hadjar consists of a small temple, dedicated to Khnumis by the Roman emperor, Nero and Titus. At Ain Amoor, between this oasis and the Oasis Magna, is a temple built under the Roman empire.—Herodotus, iii. 26; Strabo, ii. p. 130, xvii. pp. 790, 791, 813; Ptolemy, iv. 5, 37; Minutoli, *Reise zum Tempel des Jupiter Ammon* (Berlin, 1824); Hoskins, *Visit to the Great Oasis* (8vo, Lond. 1837); Champollion, *L'Egypte*, p. 282.

OAT, or OATS (*Avena*), a genus of grasses, containing many species, among which are some valuable for the grain which they produce, and some useful for hay. The Linnæan genus *Avena*, less natural than most of the Linnæan genera, has been much broken up. The genus, as now restricted, has the spikelets in loose panicles, the glumes as long as the florets, and containing two or more florets; the pales firm, and almost cartilaginous, the outer pales of each floret, or of one or more of the florets, bearing on the back a knee-jointed awn, which is twisted at the base. The awn, however, tends to disappear, and often wholly disappears in cultivation. Those species which are cultivated as corn-plants have comparatively large spikelets and seeds, the spikelets—at least after flowering—pendulous. The native country of the cultivated oats is unknown, although most probably it is Central Asia. There is no reference, however, to the oat in the Old Testament; and although it was known to the Greeks, who called it *Bromos*, and to the Romans, it is probable that they derived their knowledge of it from the Celts, Germans, and other northern nations. It is a grain better suited to moist than to dry, and to cold than to warm climates, although it does not extend so far north as the coarse kinds of barley. The grain is either used in the form of Groats (q. v.) or made into meal. Oatmeal cakes and porridge form great part of the food of the peasantry of Scotland and of some other countries. No grain is so much esteemed for feeding horses. Besides a large quantity of starch—about 65 per cent.—and some sugar, gum, and oil, the grain of oats contains almost 20 per cent. of nitrogenous principles, or Proteine (q. v.) compounds, of which about 16 or 17 parts are *Avenine*, a substance very similar to *Caséine* (q. v.), and two or three parts gluten, the remainder albumen. The husk of oats is also nutritious, and is mixed with other food for horses, oxen, and sheep. From the starchy particles adhering to the husk or seeds after the separation of the grain, a light dish, called *sowans*, is made in Scotland by means of boiling water, was once very popular, and is very suitable for weak stomachs. The grain is sometimes mixed with barley for distillation. The Russian beverage called *quass* is made from oats. The straw of oats is very useful as fodder, bringing a higher price than any other kind of straw. —The varieties of oats in cultivation are very

numerous, and some highly esteemed varieties are of recent and well-known origin. It is doubtful if they really belong to more than one species; but the following are very generally distinguished as species: 1. COMMON OAT (*A. sativa*), having a very loose panicle, which spreads on all sides, and two or three fertile florets in each spikelet, the palea quite smooth, not more than one floret awned; 2. TARTARIAN OAT (*A. orientalis*), also called HUNGARIAN OAT and SIBERIAN OAT, distinguished chiefly by having the panicle much more contracted, and all turned to one side; 3. NAKED OAT (*A. nuda*), differing from the Tartarian Oat chiefly in having the palea very slightly adherent to the seeds, which, therefore, fall readily out of them, whilst in the other kinds they adhere closely; 4. CHINESE OAT (*A. chinensis*), which agrees with the last in the characters of the palea and seeds, but is more like the Common Oat in its panicle, and has more numerous florets, 4–8, in the spikelet; 5. SHORT OAT (*A. brevis*), which has a close panicle turned to one side, the spikelets containing only one or two florets, each floret awned, the grains short. Almost all the varieties of oat in cultivation belong to the first and second of these species. The Naked Oat is cultivated in Austria, but is not much esteemed. The Chinese Oat, said to have been brought by the Russians from the north of China, is prolific, but the grain is easily shaken out by winds. The Short Oat is cultivated as a grain-crop on poor soils at high elevations in the mountainous parts of France and Spain, ripening where other kinds do not; it is also cultivated in some parts of Europe as a forage plant.—Besides these, there is another kind of oat, the BRISTLE-POINTED OAT (*A. strigosa*), regarded by some botanists as belonging even to a distinct genus, *Danthonia*, because the lower palea is much prolonged, and instead of merely being bifid at the point, as in the other oats, is divided into two long teeth, extending into bristles. The panicle is inclined to one side, very little branched; the florets, 2 or 3 in a spikelet, all awned, the grain rather small. This plant is common in cornfields, is cultivated in many countries, but chiefly on poor soils, and was at one time much cultivated in Scotland,

Wild Oat (*Avena fatua*).

but is now scarcely to be seen as a crop.—Not unlike this, but with the panicle spreading equally on all sides, the outer palea merely bifid, and long hairs at the base of the glumes, is the WILD OAT (*A. fatua*), also frequent in cornfields, and a variety

of which is cultivated in some northern countries for meal, but which is more generally regarded by farmers as a weed to be extirpated, springing up so abundantly in some districts as to choke crops of better grain. Its awns have much of the hygro-metrical property which gains for *A. sterilis*, a species found in the south of Europe, the name of the ANIMAL OAT, because the seeds when ripe and fallen on the ground resemble insects, and move about in an extraordinary manner through the twisting and untwisting of the awns. The seed of the WILD OAT has been sometimes used instead of an artificial fly for catching trout.—Amongst the species of oat useful not for their grain but for fodder are the DOWNY OAT-GRASS (*A. pubescens*) and YELLOW OAT-GRASS (*A. flavescens*), both referred by some botanists to the genus *Trisetum*—the short awn being like a middle tooth in the bifid palea—and both natives of Britain, the former growing on light ground and dry hills, especially where the soil is calcareous, the latter on light meadow lands.—Other species are found in Britain, continental Europe, North America, Australia, &c. In some parts of the Sahara are bottoms of ravines richly productive of a species of oat-grass (*A. Forskalii*) much relished by camels.

Far more ground is occupied with oats in Scotland than with any other grain. In all the higher districts, it is almost the only kind of grain which is cultivated. Throughout Scotland, it is the crop that is chiefly sown after land has been in pasture for one or more years. The seed is generally sown broadcast over the ploughed land, which is afterwards well harrowed and pulverised. It is of the utmost importance to have the latter operations well done, as it prevents the attacks of insect larvæ. On soils that are infested with annual weeds, such as charlock, it is common to drill the seed, which permits the land to be hand-hoed and thoroughly cleaned. Oats thrive best upon deep and rich soils, and yield but poorly on thin sandy soils, where they suffer sooner from drought than barley, rye, or wheat. On good soils, it is common to dress oats with 2 to 3 cwt. of guano to the acre. The plant is not easily injured by large applications of heterogeneous manures. The Potato Oat is a variety generally cultivated in the best soils and climates. It is an early and productive variety. The Hopetoun Oat is also much sown in the earliest districts. The Sandy Oat is still more largely sown, more particularly when the climate is inferior and wet. It is not liable to be lodged with rains, and the straw is of fine quality for fodder. All these are varieties of the Common Oat. The White and Black Tartarian are much cultivated in some districts. They are very productive.—On the continent of Europe, this grain is seldom seen of quality equal to what is produced in Scotland; and even in most parts of England, the climate is less suitable to it, and it is less plump and rich.

OATES (*alias* AMBROSE), TITUS, was the son of a ribbon weaver, who, having first become an Anabaptist minister under Cromwell, took orders and a benefice in the English Church after the Restoration. Titus appears to have been born about 1650 in London. He was a pupil of Merchant Taylors' School, whence he passed to Trinity College, Cambridge, took orders, and received a small living from the Duke of Norfolk. This position, however, he forfeited, in consequence of a malicious prosecution, in which he narrowly escaped conviction for perjury; and having been afterwards appointed to the chaplaincy of one of the king's ships, he was expelled from it on a charge still more disgraceful. In this extremity, he conformed to the Roman Catholic Church, and was admitted as a scholar of

the Jesuits' College at Valladolid; but was expelled for misconduct, after a trial of a few months. He was again received by the Jesuits, on his earnest protestations of repentance, at St Omer, where he was no less unsuccessful, and was finally dismissed by them in the early part of 1678. He now, as a mere vagabond adventurer, set himself to live by his wits, in the evil exercise of which he devised, about this time, the atrocious scheme with which his name is identified in history. Just then, great excitement and alarm pervaded the Protestant party in England. It was well known that Charles was at heart a Roman Catholic; and his brother, the Duke of York, afterwards James II., was an active and avowed zealot on the same side. The growing confidence of the Roman Catholics was unconcealed; and with or without instant reason, the cry so often since heard arose, and was everywhere re-echoed, that the 'Protestant religion was in danger.' In this fevered state of general feeling, O. saw his opportunity, and dexterously and boldly availed himself of it. He communicated to the authorities the details of a pretended plot, the figment of his own brain, the main elements of which were a rising of the Catholic party, a general massacre of Protestants, the burning of the city of London, the assassination of the king, and the invasion of Ireland by a French army. In certain of its items, the fiction was devised with considerable ingenuity to catch the popular belief. By the strangest coincidence, moreover, there just then occurred in aid of it a series of events which seemed conclusively to attest its genuineness. A correspondence, the object of which was the propagation of the Roman Catholic religion, came to light between the secretary of the Duke of York and Pere La Chaise, the confessor and confidant of Louis XIV. Danby, the prime minister, it also appeared, had been busy with intrigues in the same quarter. Finally, Godfrey, the zealous magistrate through whom publicity was first given to 'the plot,' was found mysteriously murdered. After this, could reasonable doubt exist? Was not the English St Bartholomew already begun? All London went wild with fear and rage; and it seemed at one time likely that a massacre of Roman Catholics would be substituted for the dreaded extermination of the Protestants. The parliament, which might have done something to allay the excitement, was itself swept headlong away by it. The king alone, whose life was threatened, but who, dissolute and indolent as he was, wanted neither courage nor shrewdness, much to his honour, scornfully insisted that the plot was merely some insane delusion, and tried, so far as he could, to control the excesses which followed. Too probably, his interference was of the characteristically easy, *insouciant* kind; in any case, it did not avail. The story of O. was universally believed; and he became the popular hero of the day. A pension of £900 a year was granted him; a suite of apartments in the palace at Whitehall was set apart as sacred to his use; and wherever he went, the Protestant public wildly cheered him as their saviour. With the aid of a set of suborned ruffians, only one degree less foul than himself, convictions of his victims were readily obtained,

judges and juries vying with each other in their unquestioning reception in evidence of the grossest and most manifest perjuries; and many innocent Roman Catholic gentlemen died the death of traitors at the block. Over the space of two years, the base success of O. was signalled by a series of judicial murders. Naturally, however, as reason resumed its sway, doubts began to be felt; and on the execution of a venerable and respected nobleman, Viscount Stafford, with a strong shock of pity and remorse, public suspicion awoke, and a violent reaction set in. It was only, however, on the accession of James II. in 1685 that retribution overtook the malefactor. Active steps against him were then taken. He was tried before the Court of King's Bench, convicted of perjury, and sentenced to be pilloried, whipped at the cart's tail, and afterwards

Oates in the Pillory.—From a Contemporary Print.

imprisoned for life. We might wonder a little at the leniency of the sentence, were it not thus to be explained: it was intended that the severity of the first two items of punishment should render the last one superfluous, and that the wretch should die under the lash of the executioner. But the hide of O. was beyond calculation tough; and horribly lacerated, yet living, his carcass was conveyed to the prison, from which it was meant never more to issue. Very strangely, however, the next turn of the political wheel brought back the monster to the light of day and to prosperity. When the revolution of 1688 placed William on the throne, the Protestant influence triumphed once

more. In the outburst of enthusiasm which ensued, what more natural than that O. should be glorified as a Protestant martyr? Parliament solemnly declared his trial an illegal one; he was pardoned, and obtained his liberty; and in order to his perfect enjoyment of it, a pension of £300 a year was granted him. He was, however, no more heard of; he passed his seventeen remaining years in obscurity, and died 13th July 1705, at the age of fifty-six.

OATH (Ang.-Sax. *ath*, Ger. *eid*), in the religious use of the word, may be defined an expressed or implied calling upon the Almighty to witness the truth of an asseveration, or the good faith of a promise; with which is ordinarily conjoined an imprecation of his vengeance, or a renunciation of his favour, in case the asseveration should be false, or the promise should be broken. This practice has prevailed, in some form or other, in almost all the religions of the ancient, as well as of the modern world. It supposes, however, a belief of the existence of a provident Supreme Being, in order to its moral efficacy as a safeguard of truth. Among the Jews, we find instances in Gen. xiv. 22, xxi. 24, xlvii. 31, l. 5, confirmed even by the example of God himself, Numb. xiv. 28, Jerem. xlv. 26, Isai. lxii. 8. It was strictly forbidden to the Jews to swear by false gods (Amos viii. 14, Jerem. xii. 16). The form of oath was probably variable, either a direct adjuration, as 'The Lord liveth,' or an imprecation, 'The Lord do so to me;' but in all cases, the strongest denunciations are held out against the false swearer (Exod. xx. 7, Levit. xix. 12). Oaths were employed, both judicially and extrajudicially, by the ancient Egyptians, Assyrians, Medes, and Persians, as well as by the Greeks, and also by the Romans. The forms were very various—one of the most solemn consisting in the act of placing the hand on the altar of the deity who was invoked as witness. In the judicial proceedings of both the last-named nations, oaths were employed, but not universally; and in examples of their extrajudicial use, the literatures of both abound. In the Christian dispensation, the solemnity of an oath is enhanced by the elevated idea of the sanctity and perfection of the Deity.

The lawfulness and fitness of the practice, under circumstances of due solemnity, are commonly recognised by Christians. Some communions, of which the most remarkable are the Moravians and the Society of Friends, applying literally the words of Christ (Mat. v. 34), regard all oaths as unlawful. But other communions generally restrict this prohibition to ordinary and private discourse, and find in Rom. i. 9, 2 Cor. xi. 21, Gal. i. 20, Phil. i. 8, and 1 Thessal. ii. 5, full warrant for the lawfulness of oaths in judicial and other solemn use. From some passages of the Fathers, it might seem that they shared the difficulties of the Quakers and Moravians on the subject of the lawfulness of swearing; but these Fathers for the most part referred to the oaths required of Christians by the pagans, which generally involved a recognition of particular pagan divinities; and they condemned these pagan oaths, rather as involving or even directly containing a profession of the popular paganism, than as unlawful in themselves. The Christians of the later ages may perhaps be said to have multiplied in an opposite degree the occasions of oaths; especially of what were called 'purgatorial' oaths, in which a party charged with a crime justified himself by swearing his innocence. These oaths were commonly accompanied by some imprecatory form or ceremonial, and were often expected to be followed by immediate manifestations of

the divine vengeance upon the perjurer. The common instrument of attestation on oath was the Bible or some portion of it; but oaths were sometimes sworn on the relics of saints, or other sacred objects; sometimes simply by raising the hand to heaven, or by laying it upon the breast or the head. In canonical processes, the oath was often administered to the party kneeling. The forms varied very much; the most general being that which the English oath still retains (*Sic me Deus adjuvet*). Divines commonly require, in order to the lawfulness of an oath, three conditions (founded upon Jerem. iv. 2), viz., *truth*, *justice*, and *judgment*—that is to say (1), that the asseveration, if the oath be assertive, shall be *true*, and that the promise, if the oath be promissory, shall be made and shall be kept in *good faith*; (2), that the thing promised shall be objectively lawful and good; (3), that the oath shall not be sworn without due discretion and deliberation, and without satisfactory reasons founded on necessity, or at least on grave and manifest utility.

The Mohammedans do not employ oaths in their judicial proceedings; but they regard deliberate perjury, even when extrajudicially committed, as sinful, and deserving of God's vengeance. For this, however, they require that the oath should be an express adjuration of God himself by some one of his well-known holy names; that the jurant should be of full age and intelligence; and that the oath should be sworn deliberately, and with the intention of swearing.

OATH, in point of law, is that kind of solemn declaration which is necessary as a condition to the filling of some office more or less public, or of giving evidence in a court of justice. Nearly all the great public offices of the state in this country can only be filled by persons who are willing to take an oath before acting in such office. The most important office of all—that of king or queen of Great Britain—requires a Coronation Oath (q. v.). Members of parliament also require to take the oath of fidelity and true allegiance, and promising to maintain the succession, in a full house, before taking their places (29 and 30 Vict. c. 19). Quakers and others may make an affirmation to the same effect. In 1868, 1869, and 1871, great changes were made as to oaths. The oath of allegiance and the official oath must now be taken by the great officers of state, such as the First Lord of the Treasury, Chancellor of the Exchequer, Lord Chancellor, Secretaries of State, &c., in England. In Scotland, the same are taken by the Lord Keeper of the Great Seal and Privy Seal, Lord Clerk Register, Lord Advocate, and Lord Justice-Clerk; so in Ireland by the Lord Lieutenant, Lord Chancellor, and two others. The oath of allegiance and the judicial oath are taken by the superior judges in each kingdom, justices of the peace, and Scotch sheriffs. No others, except under the Clerical and Parliamentary Oaths Acts, are to take the oaths of allegiance, supremacy, and abjuration, or any oath substituted for these. All others who used formerly to take oaths now make declarations of fidelity in their office, and in some cases also one of secrecy.

The most important oaths affecting the general public are those which are required to enforce the truth from witnesses in courts of justice. It may be stated that jurymen, where they are called upon to exercise their functions, are also required to take an oath. The oath is read to the juror thus—'You shall well and truly try the issue between the parties, and a true verdict give, according to the evidence, so help you God;' and the juror kisses the New Testament. Witnesses who are called to give evidence must all be first sworn in a similar manner, the words being, 'The evidence you shall give shall be

the truth, the whole truth, and nothing but the truth, so help you God.' Hence, a witness must have sufficient understanding to know the nature and obligations of an oath; and on this ground, young children are incompetent to be witnesses. The usual practice in England and Ireland is, for the witness, after hearing the oath repeated by the officer of court, to kiss the four gospels by way of assent; and in Scotland, the witness repeats similar words after the judge, standing and holding up his right hand, 'swearing by Almighty God, as he shall answer to God at the Great Day of Judgment,' but without kissing any book. Jews are sworn on the Pentateuch, keeping on their hats, and the oath ends with the words, 'so help you Jehovah.' A Mohammedan is sworn on the Koran; a Chinese witness has been sworn by kneeling and breaking a china saucer against the witness-box. Thus, the mere form of taking the oath is immaterial; the witness being allowed to take it in whatever form he considers most binding upon his own conscience.

The policy of insisting upon the religious formalities attending the taking of an oath, has been much discussed of late years, and concessions have from time to time been made by the Legislature in the direction of greater latitude. Previous to 1869, atheists and persons who admitted that they had no religious belief, were excluded from giving evidence in courts of justice; which exclusion occasionally led to the frustration of justice. The objection of Quakers, Moravians, and Separatists to taking the oath was long respected, as not being fundamentally at variance with a due sense of religious feeling; hence they were allowed by statute to take an affirmation instead of the oath. A further concession was made in 1854 to those who, not being Quakers, yet refused to take the oath from sincere conscientious motives, such being allowed also to affirm. Again, in 1869, a statute was passed, excluding all reference to religious tests, and enacting that, where the judge is satisfied that the taking of the oath would have no binding effect on the conscience of the person called to give evidence, such person shall be allowed to make an affirmation, in which he 'solemnly promises and declares that the evidence given by him to the Court shall be the truth, the whole truth, and nothing but the truth.' The right of a member of Parliament to affirm instead of taking the usual oath was brought conspicuously before the country in 1880, when Mr Bradlaugh, member for Northampton, refused to take the oath, on the ground that the religious expressions made use of therein had no meaning for him. After a series of debates, a motion passed the House that Mr Bradlaugh be allowed to make an affirmation; which he thereupon did, and took his seat. It was, however, decided by the law-courts that he was not entitled to make affirmation in this connection; and though he afterwards expressed his desire to take the oath, a vote of the House declined to permit him. In 1883, the government brought in a bill permitting the affirmation in such cases, but were defeated by a small majority. In the new parliament of 1886, Mr Bradlaugh did take the oath.

When a witness, after being duly sworn, gives false evidence in a court of justice or in a judicial proceeding, and his evidence so falsely given is material, he commits the offence of Perjury (q. v.). As a general rule, perjury cannot be committed except in some judicial proceeding, or rather the giving of false evidence cannot be punished except it has been given in some judicial proceeding. The practice formerly existed of persons

voluntarily taking oaths in various matters not connected with any judicial proceeding; and creditors often in this manner sought to add to other securities by insisting on a formal oath before a justice of the peace, in some isolated matter of fact. This practice was put an end to by the statute 5 and 6 Will. IV. c. 62, by which justices of the peace were prohibited from administering or receiving such oaths touching any matter or thing whereof such justice has not jurisdiction or cognizance by some statute. It is left to some extent to the discretion of the justice whether the particular matter is one as to which it is proper to administer an oath; but when it is considered proper, the declaration may be made in the form given by that statute; and if the party make a false declaration, he commits a misdemeanour. Unlawful oaths generally mean oaths taken by members of secret and illegal societies of a treasonable description; and statutes long ago passed to inflict penalties on all who took or administered such oaths.

OATH OF CALUMNY, in Scotch Law, means an oath taken by a party at the instance of his opponent, that the allegations were well founded. Oaths of verity and credulity are oaths that a debt or claim is well founded.

OATHS, MILITARY. The taking of the oath of fidelity to government and obedience to superior officers, was, among ancient armies, a very solemn affair. A whole corps took the oath together, sometimes an entire army. In modern times, when so many other checks are used for maintaining discipline, the oath has become little more than a form. In the United Kingdom, a recruit enlisting into the army or militia, or a volunteer enrolling himself, swears to be faithful to the sovereign, and obedient to all or any of his superior officers; also to divulge any facts coming to his knowledge which might affect the safety of his sovereign, or the stability of that sovereign's government. The members of a court-martial take an oath to try the cases brought before them justly, according to the evidence, to keep secret the finding until confirmed by the crown, and to keep secret always the opinions given by the members individually. The only other military oath is the common oath of a witness before a court-martial to tell the truth, the whole truth, and nothing but the truth.

OB, or **OBI**, the great river of Western Siberia, rises in two branches, the Bia and the Katune or Katunga, both of which have their origin in the Altai Mountains, within the frontier of the Chinese dominions, about lat. 49° N., and long. 90° E. These branches, flowing in a north-west direction, unite to form the Ob at the town of Biisk in lat. 52° 30' N., long. 85° E. Pursuing a winding course, with a general north-west direction, the Ob reaches the meridian of 75° E., when it turns west, and maintains that direction to its confluence with the Irtysh, the greatest of its tributaries. It then flows north-west, north, and north-east, to its mouth in the Gulf of Ob, which it reaches after a course of 3000 miles. Its chief affluents on the right are the Tom—a swifter stream than the Ob, 400 miles in length, and navigable for the last 280 miles from the beginning of May till July—the Tchulim, and the Ket. The principal affluent on the left is the Irtysh, which, rising within the frontier of the Chinese territories, traverses the Altai Mountains, and after a course longer than that of the Ob itself, joins that river 250 miles below Tobolsk. The trade of the Irtysh, of which the centre is Tobolsk, is important. The principal towns on the banks of the Ob are Narim, Sargut, Berezow, and Obdorsk.—The Gulf of Ob is a long inlet of the Arctic Ocean,

450 miles in length by about 100 miles in breadth. At present, only a few steamers ply on the great water-system of the Ob; but that system, communicating as it does between Siberia, the Chinese territories, and European Russia, is, without doubt, destined to become a great commercial thoroughfare. The explorations of Professor Nordenskiöld, but more especially the tentative voyages of Captain Wiggins in 1874 and 1876, from Dundee through the Kara Sea to the Gulf of Ob, have amply proved the feasibility of this direct route. This river is very rich in fish. Below its junction with the Irtysh, it divides itself into several parallel streams; and in the flood season it inundates great tracts of country, and presents the appearance of a waste of waters, its desolate uniformity broken only by the occasional tree-tops that rise above the surface. At Obdorsk, about 20 miles south of the southern border of the Gulf of Ob, the river freezes in the middle of October, and breaks up about the middle of May.

OBADIAH, one of the 'minor prophets' of the Old Testament, regarding whom absolutely nothing is known. His book or 'vision'—the shortest of the Jewish Scriptures—appears, from internal evidence, to have been composed after the destruction of Jerusalem by the Chaldeans, 588 B.C., and consists of two parts. The first is a prophecy of the downfall of Edom. The second foretells the future redemption and glory of the house of Jacob, in which Edom—for his unbrotherly conduct—shall not share, but, on the contrary, be burned up as 'stubble.'

O'BAN, a parliamentary burgh and seaport, Argyshire, Scotland, on a bay of the same name, 20 miles (in direct line) north-west of Inveraray. The bay is protected from every wind by the island of Kerrera on the west, and by the high shores of the mainland, and is overlooked on the north by the picturesque ruins of Dunolly Castle. It is from 12 to 24 fathoms deep, and although the girdle of hills that seems to surround it gives it the appearance of a lake, it is easily accessible, and could afford anchorage to 300 sail. O. is the great rendezvous for tourists in the West Highlands. Its importance dates chiefly from the beginning of the present century. The burgh now contains a number of churches, several hotels and inns, schools, banks, &c. Within three miles of O. is Dunstaffnage Castle, which is said to have been the seat of the Scottish monarchy previously to its transference to Scone. The Stone of Destiny, which now supports the coronation chair in Westminster Abbey, and was carried thither from Scone by Edward I., came from Dunstaffnage Castle. A railway from Callander to O., connecting it with Edinburgh and Glasgow, was opened in 1880. Pop. of O. (one of the Ayr group of parl. burghs) in 1871, 2426; (1881) 4046.

OBĒ, or **OBI** (etymology unknown), the name given to the magical arts or witchcraft practised by a class of persons among the negroes of the West India. The practitioner is called an *Obeah-man* or *Obeah-woman*. It differs in no essential respect from the corresponding superstitions all the world over. See **MAGIC**, **WITCHCRAFT**.

OBEDIENCE, in Canon Law, means the duty by which the various gradations in ecclesiastical organisation are held subject, in all things consistent with the law of God or of the church, to the several superiors placed immediately above each, respectively, in the hierarchical scale. Thus priests and inferior clergy owe canonical obedience to the bishop, and priests are bound thereto by a solemn promise administered at ordination. The bishop primitively took a similar oath to the metropolitan; but by the modern law, the jurisdiction of the

metropolitan is confined to the occasions of his holding a visitation, or presiding in the provincial synod. Bishops, by the present law of the Roman Catholic Church, take an oath of obedience to the pope. This obedience, however, is strictly limited by the canons, and is only held to bind in things consistent with the divine and natural law. In ecclesiastical history the word Obedience has a special signification, and is applied to the several parties in the church, which, during the great Western Schism (q. v.), adhered to the rival popes. Thus we read of the 'Roman Obedience,' which included all who recognised the pope chosen at Rome, and the 'Avignon Obedience,' which meant the supporters of the Avignon pope. So, again, historians speak of 'the Obedience of Gregory XII,' and 'the Obedience of Benedict XIII,' &c. Applied to the monastic institute, obedience means the voluntary submission which all members of religious orders vow, at the religious profession, to their immediate superiors, of whatever grade in the order, as well as to the superior general, and still more to the rules and constitutions of the order. This forms, in all orders, one of the essential vows. It is, however, expressly confined to lawful things; and although it is held that a superior can command certain things under pain of sin, yet Roman Catholics repudiate the notion that the command of a superior can render lawful, much less good, a thing which is, of its own nature, or by the law of God, sinful or bad. The name Obedience is sometimes given to the written precept or other formal instrument by which a superior in a religious order communicates to one of his subjects any special precept or instruction—as, for example, to undertake a certain office, to proceed upon a particular mission, to relinquish a certain appointment, &c. The instruction is called an obedience, because it is held to bind in virtue of religious obedience.

OBEID. See **IL OBEID**.

O'BELISK, a word derived from the Greek *obelos* and *obeliskos*, signifying a spit, applied to prismatic monuments of stone and other materials, terminating with a pyramidal or pointed top. These monuments, called *tekhen*, were placed upon bases before gateways of the principal temples in Egypt, one on each side of the door. They served in Egyptian art for the same purposes as the stelæ of the Greeks and columns of the Romans, and appear to have been erected to record the honours or triumphs of the monarch. They have four faces, are cut out of one piece, and are broader at the base than at the top, at a short distance from which the sides form the base of a pyramidion in which the obelisk terminates. They were placed upon a cubical base of the same material, which slightly surpassed the breadth of their base. Each side of the obelisk at the base measures $\frac{1}{4}$ th of the height of the shaft, from the base line to that where the cap, or pyramidion commences. The cap is also $\frac{1}{4}$ th of the same height. Their sides are slightly concave, to increase their apparent height. Their height varies from upwards of 100 feet to a few inches, the tallest known being that of Karnak, which rises to 105 feet 7 inches. The sides are generally sculptured with hieroglyphs and representations, recording the names and titles of kings, generally in one line of deeply-cut hieroglyphs down each side. The pyramid of obelisks was sometimes decorated with subjects. The mode by which they were made appears to have been to hew them first in the rough out of a solid piece in the quarries, and one unfinished specimen thus prepared still remains in the quarries of Syene. They were transported down the Nile during the inundation, on

rafts to the spot where they were intended to be placed, and raised from their horizontal position by inclined planes, aided by machinery. Some obelisks, before their erection, had their pyramid capped with bronze gilded, or gold, the marks of such covering still being evident on their surfaces. Under the Roman empire, they were raised by pulleys and heavy tackle. The difficulty of erecting the fallen ones in the ages of the renaissance, as also the mechanical appliances for the lowering from its original site the obelisk of Luxor in 1831, and erecting it in the Place de la Concorde in 1833 by Le Bas, shew the difficulties experienced by the ancients. The use of obelisks is as old as the appearance of art itself in Egypt; these grand, simple, and geometric forms being used in the 4th dynasty, and continued till the time of the Romans. Their object is enveloped in great obscurity. At the time of the 18th dynasty, it appears that religious ceremonies and oblations were offered to the obelisks, which were treated as divinities. Their sepulchral use is evinced by their discovery in the tombs of the 4th dynasty, and the vignettes of early pyri. No large obelisk is older than that of Matarieh or Heliopolis, erected by Osortesen I. about 1900 B.C.; and that of Beggig or Crocodilopolis is, in reality, only a stele. Thothmes I. placed two of large size before the granite sanctuary of Karnak, and his daughter Hatasu, two others of above 90 feet high, before the second propylæon. Additional sculptures were made on these obelisks by Sethos I., who restored them. Thothmes III. appears to have erected many obelisks. The oldest is that of the Atmeilan or Hippodrome of Constantinople. Two others, which formerly stood at Heliopolis, were subsequently re-erected by Rameses II. at Alexandria, and have been popularly known as Cleopatra's Needles. One, which long lay prostrate, was after an adventurous voyage brought to London in 1878, and erected on the Thames Embankment. The other, presented by the Khedive to the United States, was set up at New York in 1881. The highest of all obelisks, that of St John of the Lateran, appears to have been removed from Thebes, and set up by Thothmes IV. A small obelisk of Amenophis II., said to have been found in the Thebaid, apparently from Elephantine, is in the collection of the Duke of Northumberland at Sion. Sethos I. commenced the Flaminian obelisk, subsequently completed by Rameses II., and placed at the temple of Heliopolis. It was removed to Rome by Constantius, and found 16 feet under the surface in the pontificate of Gregory XIII., and erected in that of Sextus V. by the architect Fontana. The other obelisks of Rameses II. are, the one at the Luxor quarter of Thebes, the companion of which was removed to the Place de la Concorde at Paris in 1833; the two obelisks of San or Tanis; that of the Boboli Gardens of Florence, transported from the circus of Flora at Rome; the obelisk of the Rotonda at Rome, erected by Clement XII., 1711 A.D.; and that of the Villa Mattei, which decorated the Ara Cæli of the Capitol. A fragment of another obelisk was in the Collegio Romano. No obelisks are known of other monarchs till the 26th dynasty. That of the Monte Citorio at Rome, erected by Psammetichus II. at Heliopolis, was transported by Augustus to the Campus Martius, having been exhumed 1748 A.D., and erected by the architect Antinori in that of Pius VI. Two other obelisks of small size, made of black basalt, dedicated by Nekhterhebi or Nectanebes II. at Hermopolis, commonly known as the obelisks of Cairo, are in the British Museum. Ptolemy Philadelphus is said to have erected in the Arsinoeum at Alexandria a plain obelisk of 80 cubits, cut in the quarries by Nectabia. It was set

up by the architect Satyrus. Two obelisks, erected by Ptolemy Euergetes II. and his wife Cleopatra, stood before the temple of Philæ, one of which was removed to Corfe Castle by Mr Bankes. The so-called Pamphiliano obelisk at Rome, erected by E. Bernin in 1651, in the Piazza Navona, under the pontificate of Innocent X., was removed from the Circus of Maxentius, having, as their hieroglyphical legends testify, been originally erected by Domitian before the Serapeum at Rome. The last of the Roman obelisks was the Barberini, which was found in 1633 on the site of the Circus of Aurelian, and finally erected in 1822 on the Monte Pincio. It was placed by the Emperor Hadrian before the mausoleum or cenotaph either of himself or Antinous, between 132—138 A.D. Barbarous hieroglyphs, found on the Sallustian obelisk, are copied from the Flaminian obelisk. It is supposed to have been transported to Rome, unadorned with hieroglyphs, by Sallustius Crispus, prefect of Numidia, and to have been set up in the gardens of Sallust, in the reign of Vespasian. It was erected by Antinori, 1789, before the Church of Trinita del Monte. It has been seen how, on the renaissance of the arts, the obelisks were restored and applied to the embellishments of modern Rome, either as columns in the centres of piazzas or squares, or else as the ornaments of fountains; one obelisk being set up alone in the centre of the piazzas and places of Italy and France, while in antiquity they always stood in pairs before the Pylons.

Two small obelisks, and the apex of a third, have been found in Assyria, in shape of truncated prisms, the apices step-shaped. The most interesting is that of the north-west palace of Nimrud, of black marble, is 5 feet 9 inches high. Each side has five compartments of bas-reliefs, representing the tribute and offerings made to the Shalmanaser. It is covered with a cuneiform inscription, recording the annals of the king's reign, from his 1st to his 31st year. On it is represented

Obelisks in front of a Temple.

the tribute of Jehu, king of Israel. A second obelisk, of white marble, measures 8 feet 2 inches high, is covered with bas-reliefs, representing scenes of war and tributes, winding round it like those of a Roman triumphal column. On it is an inscription of Shamas-Pul. The broken apex of a third has a dedication from Ashur-inir-pul II. An obelisk of Semiramis at Babylon is mentioned by Diodorus, and another of Aricarus was interpreted by Democritus. Under the Roman empire, obelisks were

used as gnomons, placed in the public spaces, or erected in the *spina* of the *circi*. The first removal of obelisks to Rome took place in the reign of Augustus, who placed one in the circus, said to have been originally erected in the reign of Semperpetuus, 85½ feet high; and another of 9 feet less, in the Campus Martius, and had it adjusted as a gnomon by the mathematician Facundus Novus; a third obelisk was erected in the Circus of Caligula and Nero in the Vatican, and originally dedicated to the sun by Nuncoreus, the son of Sesosis, on the recovery of his sight. Two other small obelisks, which decorated the mausoleum of Augustus, and were erected by Claudius or Vespasian and his sons, have been found. Other obelisks are known to have been removed by Constantius, 354 A. D. P. Victor, in his description of the quarters of ancient Rome, reckons 6 of the largest size and 42 others. The Romans added to them brazen spheres and other decorations. Some were removed to Constantinople by Theodosius the younger, and Valentinian, 390 A. D. The translation of the inscription of one of the Roman obelisks made by a Greek or Egyptian, named Hermapion, has been preserved by Ammianus Marcellinus.—Kircher, *Œdipus Ægyptiacus* (tom. iii. Rom. 1652—1654); Zoega, *De Origine et Usu Obeliscorum* (1797); Cipriani, *Sui Dodici Obelisci di Roma* (1823); L'Hôte, *Notice Historique sur les Obélisques Égyptiens* (1836); Birch, *Notes upon Obelisks* (1853); Sir Erasmus Wilson's *Cleopatra's Needle* (1878); Lieut. Goringe's *Egyptian Obelisks* (1882).

OBER-AMMERGAU, a village of Upper Bavaria, with 1200 inhabitants. See MYSTERIES AND MIRACLE PLAYS.

OBERLIN, JOHANN FRIEDRICH, distinguished for his active benevolence and usefulness, was born at Strasburg, 31st August 1740; and in 1766 became Protestant pastor of Waldbach, in the Ban de la Roche or Steintal, a wild mountainous district of Alsace. Here he spent the remainder of his life, combining an affectionate diligence in the ordinary duties of the pastorate, with wise and earnest endeavours to promote the education and general prosperity of the people. The district had suffered terribly in the Thirty Years' War, and the scanty population which remained was sunk in poverty and ignorance. O. introduced better methods of cultivating the soil, and various branches of manufacture. The population, which was scarcely 500 when he entered on his labours, had increased to 5000 at the close of the century. Yet, though animated in all his actions by the most pure and disinterested piety, it may be questioned if he did not carry his moral supervision too far when he kept a register of the moral character of his parishioners, and searched with the minuteness though not the motives of an inquisitor, into the most insignificant details of their private life. O. was ably assisted in his reformatory labours by his pious housekeeper, Luise Schepler, who survived her master eleven years. He died 1st June 1826. Notwithstanding the humble sphere in which his days were spent, his fame as a philanthropist has extended over the world, and his example has stimulated and guided many. See *Brief Memorials of Oberlin*, by the Rev. T. Sims, M.A. (Lond. 1830), the *Memoirs of Oberlin* (1852), the biography by Bodemann (1868), and that by Spach (Paris, 1866).

OBERON, the king of the Elves or Fairies, and the husband of Titania. The name is derived by a change of spelling from *Auberon*, more anciently *Alberon*, and that from the German *Alberich*, i. e., king of the Elves. O. is first mentioned as 'Roi du royaume de la féerie' in the old French poem of *Huon de Bordeaux, pair de France*, which was

afterwards made the basis of a popular prose romance. From the French, O. was borrowed by the English poets, Chaucer, Spenser, and others, but he is most familiarly known from his appearance in Shakspeare's *Midsummer Night's Dream*. From old French sources, also, Wieland derived part of the materials of his poem of *Oberon*.

OBESITY, or CORPULENCE, may be defined to be 'an accumulation of fat under the integuments or in the abdomen, or in both situations, to such an amount as to embarrass the several voluntary functions.' A certain degree of fatness is not only quite compatible with health, but, as has been shewn in the article *FATS, ANIMAL*, the fatty tissue is of considerable use in the animal body, partly in consequence of its physical, and partly in consequence of its chemical properties; and it is only when the fatness begins to interfere with the discharge of any of the vital powers, that it can be regarded as a morbid condition. Obesity may occur at any period of life, but it is most commonly after the fortieth year that the tendency to an inordinate accumulation of fat begins to shew itself. After that time, in the case of men, the pleasures of the table are usually more attractive than in earlier life, and much less muscular exercise is taken; while in women, the cessation of the power of child-bearing induces changes which tend remarkably to the deposition of fat. The extent to which fat may accumulate in the human body is enormous. Daniel Lambert, who died at the age of forty years, weighed 739 lbs.; his exact height is not recorded, but, according to the investigations of the late Dr Hutchinson (the inventor of the spirometer), the normal weight of a man six feet high should not exceed 178 lbs. Dr Elliotson has recorded the case of a female child, a year old, who weighed 60 lbs.; and those who are interested in the subject will find a large collection of cases of obesity in Wadd's *Cursory Remarks on Corpulence*.

The predisposing causes of obesity are a peculiar habit of body, hereditarily transmitted; inactivity; sedentary occupations, &c.; while the more immediate or exciting causes are a rich diet, including fatty matters, and matters convertible in the body into fats, such as saccharine and starchy foods, and the partaking of such a diet to a greater extent than is necessary for balancing the daily waste of the tissues. 'Fat meats, butter, oily vegetable substances, milk, saccharine and farinaceous substances are the most fattening articles of food; whilst malt liquors, particularly rich and sweet ale are, of all beverages, the most conducive in promoting obesity. The fattening effect of figs and grapes, and of the sugar-cane, upon the natives of the countries where these are abundant, is well known. In various countries in Africa and the East, where obesity is much admired in females, warm baths, indolence, and living upon saccharine and farinaceous articles, upon dates, the nuts from which palm-oil is obtained, and upon various oily seeds, are the means usually employed to produce this effect.'—Copland's *Dictionary of Medicine*, article 'Obesity.' The knowledge of the means of inducing obesity affords us the best clue to the rational treatment of this affection. It is a popular belief that the administration of acids—vinegar, for example, or one of the mineral acids—will check the deposition of fat; but if the desired effect is produced, it is only at the cost of serious injury to the digestive, and often to the urinary organs. The employment of soap and alkalies, as advocated a century ago by Dr Flemming (*A Discourse on the Nature, Causes, and Cure of Corpulency*, 1760), is less objectionable than that of acids, but the prolonged use even of these is usually prejudicial. The

efficacy of one of our commonest sea-weeds, seawrack (*Fucus vesiculosus*), in this affection has also been strongly advocated. It is prescribed in the form of an extract, and its value is probably dependent on the iodine contained in it.

A very interesting *Letter on Corpulence*, published in 1863 by Mr Banting, in which he records the effect of diet in his own case, after all medicinal treatment had failed, is well worthy of the attention of those who are suffering from the affection of which this article treats. The following are the leading points in his case. He was 66 years of age, about 5 feet 5 inches in stature (and therefore, according to Dr Hutchinson's calculations, ought to have weighed about 142 lbs.), and in August 1862 weighed 202 lbs. 'Few men,' he observes, 'have led a more active life . . . so that my corpulence and subsequent obesity were not through neglect of necessary bodily activity, nor from excessive eating, drinking, or self-indulgence of any kind, except that I partook of the simple aliments of bread, milk, butter, beer, sugar, and potatoes, more freely than my aged nature required. . . . I could not stoop to tie my shoe, nor attend to the little offices humanity requires without considerable pain and difficulty; I have been compelled to go down stairs slowly backwards, to save the jar of increased weight upon the ankle and knee joints, and been obliged to puff and blow with every slight exertion' (pp. 10 and 14).

By the advice of a medical friend, he adopted the following plan of diet: 'For breakfast I take four or five ounces of beef, mutton, kidneys, broiled fish, bacon, or cold meat of any kind except pork; a large cup of tea (without milk or sugar), a little biscuit, or one ounce of dry toast. For dinner, five or six ounces of any fish except salmon, any meat except pork, any vegetable except potato, one ounce of dry toast, fruit out of a pudding, any kind of poultry or game, and two or three glasses of good claret, sherry, or Madeira: champagne, port, and beer forbidden. For tea, two or three ounces of fruit, a rusk or two, and a cup of tea without milk or sugar. For supper, three or four ounces of meat or fish, similar to dinner, with a glass or two of claret (p. 18). I breakfast between eight and nine o'clock, dine between one and two; take my slight tea meal between five and six; and sup at nine' (p. 40). Under this treatment he lost in little more than a year (between the 26th of August 1862 and the 12th of September 1863) 46 lbs. of his bodily weight, while his girth round the waist was reduced 12½ inches. He reported himself as restored to health, as able to walk up and down stairs like other men; to stoop with ease and freedom; and safely to leave off knee-bandages, which he had necessarily worn for twenty years past. He made his own case widely known by the circulation of his pamphlet (which has passed through several editions); and 'numerous reports sent with thanks by strangers as well as friends,' shew that 'the system is a great success;' and that it is so we do not doubt, for it is based on sound physiological principles. (Mr Banting died in 1878.)

O'BIT (Lat. *obitus*, a 'going down,' 'death'), literally means the decease of an individual. But as a certain ecclesiastical service was fixed to be celebrated on the day of death (*in die obitus*), the name came to be applied to the service itself. Obit therefore signifies, in old church language, the service performed for the departed. It consisted, in the Roman Church, of those portions of the *Officium Defunctorum* which are called Matins and Lauds, followed by a Mass of the Dead, chanted, or occasionally read. Similar services are held on the day of the funeral, and on the 30th day, and the anni-

versary; and although the name obit was primitively applied only to the first, it has come to be used of them all indiscriminately.

OBJECT, in the language of Metaphysics, is that of which any thinking being or *Subject* can become cognizant. This subject itself, however, is capable of transmutation into an Object, for one may think about his thinking faculty. To constitute a metaphysical object, actual existence is not necessary; it is enough that it is conceived by the subject. Nevertheless, it is customary to employ the term objective as synonymous with real, so that a thing is said to be 'objectively' considered when regarded in itself, and according to its nature and properties, and to be 'subjectively' considered, when it is presented in its relation to us, or as it shapes itself in our apprehension. Scepticism denies the possibility of objective knowledge; i. e., it denies that we can ever become certain that our cognition of an object corresponds with the actual nature of that object. The verbal antithesis of objective and subjective representation is also largely employed in the fine arts, but even here, though the terms may be convenient, the difference expressed by them is only one of degree, and not of kind. When a poem or a novel, for example, obtrudes the peculiar genius of the author at the expense of a clear and distinct representation of the incident and character appropriate to itself, we say it is a subjective work; when, on the contrary, the personality of the author retires into the background, or disappears altogether, we call it objective. The poems of Shelley and Byron; the novels of Jean Paul Richter, Bulwer Lytton, and Victor Hugo; and the paintings of the Pre-Raphaelites belong essentially to the former class; the dramas of Shakspeare, the novels of Scott, and the poems of Goethe, to the latter.

OBJECT-GLASS, the glass in a Telescope (q. v.) or Microscope (q. v.), which is placed at the end of the tube nearest the object, and first receives the rays of light reflected from it.

O'BLATES (Lat. *oblatus*, *oblata*, 'offered up'), the name of a class of religious bodies in the Roman Catholic Church, which differ from the religious orders strictly so called, in not being bound by the solemn vows of the religious profession. The institute of oblates was one of the many reforms introduced in the diocese of Milan by St Charles Borromeo, towards the close of the 16th century. The members consisted of secular priests who lived in community, and were merely bound by a promise to the bishop to devote themselves to any service which he should consider desirable for the interest of religion. St Charles made use of their services chiefly in the wild and inaccessible Alpine districts of his diocese. This institute still exists, and has been recently introduced into England. Still more modern are the 'Oblates of the blessed Virgin Mary,' a body of French origin, which arose in the present century, and has been very widely extended; and whose chief object is to assist the parochial clergy, by holding missions for the religious instruction of the people in any district to which they may be invited. This body also has been established in England and in Ireland. Other similar institutes might be enumerated, but the constitution of all is nearly the same. There is also a female institute of oblates, which was established in Rome, about 1440, by St Francisca of Rome, and which consists of ladies associated for charitable and religious objects, and living in community, but bound only by promise, and not by vow.

OBLIGATION is a term used in Scotch Law to denote the binding effect of any legal contract, and

is often used synonymously with contract or promise. An obligation is said to be pure when it may be instantly demanded (called in England an absolute contract). An obligation is conditional when it depends, for its legal effect, on some event which may or may not happen. Obligations are also divided into verbal and written.

OBLIGATO, in Music. When a musical composition is constructed in more than one part, any part is said to be obligato which is not merely employed to strengthen the others, but is necessary to the melodic perfection of the whole. An accompaniment is said to be obligato which does not consist of mere chords, but has its own melody.

O'BOE. See **HAUTOY**.

O'BOLUS (Gr. *obolos* or *obelos*, a spit), the smallest of the four common Greek coins and weights, was originally, as is generally supposed, a small piece of iron or copper, similar in form to the head of a spit, or spear head, whence its name. In this form it was used as a coin, and a handful of 'oboli' was equivalent to a Drachma (q. v.). It was subsequently coined of silver, and in the ordinary round form, but still retained its original name; its value, both as a coin and a weight, was now fixed as the $\frac{1}{4}$ th part of a drachma, so that in the Attic system it was equivalent to 14d. and 15 $\frac{1}{2}$ Troy grains respectively; while the Æginetan obolus was worth 2 $\frac{1}{2}$ d. as a coin, and 25 $\frac{1}{2}$ Troy grains as a weight. Multiples and submultiples of this coin were also used, and pieces of the value of 5, 4, 3, 2, 1 $\frac{1}{2}$ oboli, and of $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{4}$ of an obolus respectively, are to be found in collections of coins.

O'BRIEN, WILLIAM SMITH, born in 1803, was the second son of the late Sir Edward O'Brien, Bart. of Dromoland, in the county of Clare, Ireland, and uncle of the present Lord Inchiquin; that ancient barony having recently passed to the Dromoland O'Briens on the failure of the elder branch. W. S. O. was educated at Harrow School, whence he passed to Trinity College, Cambridge. He entered parliament for the borough of Ennis in 1826, and was a warm supporter of Catholic emancipation. In 1835, he was returned on advanced liberal principles for the county of Limerick, and for several years strongly advocated the claims of Ireland to a strictly equal justice with England, in legislative as well as executive measures. Professing his inability to effect this in the united legislature, and having embroiled himself with the Speaker by refusing to serve on committees (for which refusal he was committed to prison in the House by the Speaker's order), he withdrew from attendance in parliament in 1841, and joined actively with Daniel O'Connell (q. v.) in the agitation for a repeal of the legislative union between England and Ireland. In the progress of that agitation, a division having arisen on the question of *moral* as against *physical* force between O'Connell and the party known as 'Young Ireland,' O. sided with the latter; and when the political crisis of 1848 eventuated in a recourse to arms, he took part in an attempt at rebellion in the south of Ireland, which in a few days came to an almost ludicrous conclusion. He was in consequence arrested, and having been convicted, was sentenced to death. The sentence, however, was commuted to transportation for life; and after the restoration of tranquillity in the public mind in Ireland, he, in common with the other political exiles, was permitted to return to his native country. From that date (1856) he spent much of his time in foreign travel; and although he wrote more than once in terms of strong disapproval of the existing state of things, he invariably abstained from all

active share in the political proceedings of any party. He died June 1864.

OBSCENE PRINTS, BOOKS, or PICTURES, exhibited in public render the person so doing liable to be indicted for a misdemeanour. Persons exposing them in streets, roads, or public places, are also liable to be punished as rogues and vagabonds with hard labour. An important change in the law was effected by Lord Campbell's Act (20 and 21 Vict. c. 83), which was passed to suppress the traffic in obscene books, pictures, prints, and other articles. Any two justices of the peace, or any police magistrate, upon complaint made before him on oath that such books, &c., are kept in any house, shop, room, or other place, for the purpose of sale, or distribution, or exhibition for gain or on hire, and that such things have been sold, &c., may authorise a constable to enter in the daytime, and, if necessary, use force by breaking open doors, or otherwise to search for and seize such books, &c., and carry them before the magistrate or justices, who may, after giving due notice to the occupier of the house, and being satisfied as to the nature and object of keeping the articles, cause them to be destroyed.

OBSOURANTISTS, the name given, originally in derision, to a party who are supposed to look with dislike and apprehension on the progress of knowledge, and to regard its general diffusion among men, taken as they are ordinarily found, as prejudicial to their religious welfare, and possibly injurious to their material interests. Of those who avow such a doctrine, and have written to explain and defend it, it is only just to say that they profess earnestly to desire the progress of all true knowledge as a thing good in itself; but they regard the attempt to diffuse it among men, indiscriminately, as perilous, and often hurtful, by producing presumption and discontent. They profess but to reduce to practice the motto—

A little learning is a dangerous thing.

It cannot be doubted, however, that there are fanatics of ignorance as well as fanatics of science.

OBSERVANTISTS, or OBSERVANT FRANCISCANS. Under the head **FRANCISCANS** (q. v.) has been detailed the earlier history of the controversies in that order on the interpretation of the original rule and practice established by St Francis for the brethren, and of the separate organisation of the two parties at the time of Leo X. The advocates of the primitive rigour were called *Observantes*, or *Strictioris Observantie*, but both bodies were still reputed subject, although each free to practise its own rule in its own separate houses, to the general administrator of the order, who, as the rigorists were by far the more numerous, was a member of that school. By degrees, a second reform arose among a party in the order, whose zeal the rigour of the O. was insufficient to satisfy, and Clement VII. permitted two Spanish friars, Stephen Molena and Martin Guzman, to carry out in Spain these views in a distinct branch of the order, who take the name of *Reformati*, or Reformed. This body has in later times been incorporated with the O. under one head. Before the French Revolution, they are said to have numbered above 70,000, distributed over more than 3000 convents. Since that time, their number has, of course, been much diminished; but they still are a very numerous and widespread body, as well in Europe as in the New World, and in the missionary districts of the East. In Ireland and England, and for a considerable time in Scotland, they maintained themselves throughout all the rigour of the penal

times. Several communities are still found in the two first-named kingdoms.

OBSERVATION AND EXPERIMENT are the leading features of modern science, as contrasted with the philosophy of the ancients. They are indispensable as the bases of all human knowledge, and no true philosophy has ever made progress without them, either consciously or unconsciously exercised. Thus, by Socrates, Plato, and Aristotle, no less than by Archimedes and the ancient astronomers, observation and experiment are extensively though not prominently or always obviously employed; and it was by losing this clue to the spirit of their masters' teaching, that the later disciples in these schools of philosophy missed the path of real progress in the advancement of knowledge. It was in the latter half of the 16th c. that the minds of philosophers were first *consciously* awakened to the importance of observation and experiment, as opposed to authority and abstract reasoning. This result was first occasioned by the discoveries and controversies of Galileo in Florence; and to the same end were contributed the simultaneous efforts of a number of philosophers whose minds were turned in the same direction—Tycho Brahe in Holland, Kepler in Germany, William Gilbert in England, who were shortly afterwards followed by a crowd of kindred spirits. The powerful mind of Francis Bacon lent itself to describe the newly-awakened spirit of scientific investigation, and though he ignored or affected to despise the results achieved by the great philosophers just mentioned, he learned from them enough to lay the foundation of a philosophy of inductive science, which, if we look at the course of scientific progress since his day, seems to have been almost prophetic. The difference between observation and experiment may be said to consist in this, that by observation we note and record the phenomena of nature as they are presented to us in her ordinary course; whereas by experiment we note phenomena presented under circumstances artificially arranged for the purpose. Experiment is thus the more powerful engine for discovery, since one judiciously conducted experiment may provide the data which could only result from a long course of observations.

OBSERVATORY, an institution supplied with instruments for the regular observation of natural phenomena, whether astronomical, meteorological, or magnetical. In some observatories all three classes of observation are carried on, but in most cases special attention is paid to astronomy alone, and only such meteorological observations are taken as are required for the calculation of the effect of atmospheric refraction on the position of a heavenly body; there are, however, a few observatories which are devoted solely to meteorological or magnetical observations. Confining our attention to astronomical observatories, it will be convenient to divide them into two classes—public and private observatories—the former being devoted to those observations which from their nature require to be continued on the same system for long periods of time, whilst the latter are usually founded for some special object, which may be attained with a comparatively small expenditure of time and labour.

The most important work which is carried out in public observatories is the determination of the movements of the sun, moon, and planets among the stars; and, as a corollary to this, the relative positions of the stars to which the other heavenly bodies are referred. In early times the Greek astronomers fixed these positions by means of armillary spheres and astrolabes, having concentric graduated

circles, on which the latitudes and longitudes could be read off, when a pair of sights was pointed to the heavenly body. Ptolemy made use of a quadrant, with which he measured zenith distances on the meridian; and many centuries after, Tycho Brahe converted this form of instrument into an altazimuth by mounting it on a vertical axis in connection with a horizontal or azimuth circle. With this instrument Tycho Brahe made a long series of observations of the altitudes and azimuths of the heavenly bodies at the observatory which the king of Denmark erected for him, and he also measured with great assiduity their angular distances from each other by means of a sextant, a method of observation which Flamsteed afterwards employed with a much improved form of the instrument, and which is now extensively used with the reflecting sextant, for finding the longitude at sea. It was not till the middle of the last century that the improvement of the clock by Graham enabled astronomers to rely on it for the determination of right ascensions by the times of passage across the meridian, instead of by measuring them with a graduated circle. The quadrant was then fixed in the meridian, and being attached to a massive wall, its dimensions were increased, and greater accuracy thereby secured in the determination of meridian zenith distances. Two such instruments pointing respectively north and south were erected at the Royal Observatory, Greenwich, and used by Bradley and his successors from 1750 till they were displaced by the mural circle (see CIRCLE, MURAL), an instrument vastly superior in principle, since the troublesome errors of centring of the quadrant were got rid of by combining the readings of opposite parts of a graduated circle, whilst the effect of division errors was much reduced by taking the mean of the readings at six or eight equidistant points of the circle. At the same time, the accuracy of the readings was greatly increased by the invention of the micrometer-microscope, which made it possible to measure spaces to $\frac{1}{100000}$ th of an inch. Neither the quadrant nor the mural circle, however, could be relied upon for accurate motion in the plane of the meridian, but Römer remedied this defect by inventing a separate instrument, the Transit (q. v.), which enabled astronomers to observe the times of meridian passage or transit with great accuracy, and thus to determine the differences of right ascension of the heavenly bodies by means of the apparent diurnal movement. With the transit and quadrant Bradley commenced that series of observations of the positions of the sun, moon, and planets, and of stars for reference, which have been continued ever since at Greenwich, and on which, in combination with less extensive series at Paris and Königsberg, all our tables of the motions of the heavenly bodies are founded. In modern observatories, the transit and mural circle are combined into one instrument, the transit-circle, a change which has been rendered possible chiefly by the improvement in graduated circles since the invention of Troughton's dividing engine, the unwieldy size of the old quadrants and mural circles necessitating an attachment to a massive wall. Although Reichenbach made transit-circles at the beginning of this century for several foreign observatories, including that of Dorpat, the lightness of their structure and their want of stability prevented their being introduced generally, and the mural circle held its place in the principal observatories till Sir George Airy designed the Greenwich transit-circle in 1851, an instrument of a most massive character, which has served as model for nearly all that have been constructed in recent years. The main features of the modern transit-circle are: (1) that it is not

reversible, its collimation error being determined by means of two collimators, or reversed telescopes pointing at each other and at the transit-telescope, north and south respectively; (2) that a spirit-level is not used, the level error being found by means of the reflexion of the wires from the horizontal surface of mercury. These two negative characteristics, while admitting of great massiveness in construction (the Greenwich instrument weighs more than a ton), have removed three troublesome sources of error—inequality in the pivots, lateral flexure of the telescope in the process of reversion, and the effect of currents of heated air on a spirit-level. An important auxiliary to the transit-circle is the chronograph, an American invention, which, in various forms, is now found in all well-equipped observatories, the principle in all cases being the same—viz., the registration on a revolving cylinder of paper of the times of transit across the system of spider-lines of the transit-circle, as well as of the seconds of the sidereal clock, by means of electric currents, which pass through electro-magnets, when the circuit is closed either by the observer or the clock, thus causing a momentary attraction of a piece of soft iron, and producing a corresponding mark on the paper either with a pen or a steel point. This system, while improving somewhat the accuracy of the individual observations, admits of a large number being made at intervals of two or three seconds, and leaves the observer free to make several observations of zenith distance during the passage of a star across the field of view. Allusion has been made to the importance of the sidereal clock in modern astronomy. Considerable improvements have been made in its construction since Graham's times, the original gridiron pendulum having been replaced successively by the mercurial and the zinc and steel, and the dead-beat escapement by Dennison's gravity and Airy's detached escapement. Recently an apparatus depending on the attraction of a movable magnet connected with a float in a syphon barometer has been applied by Sir George Airy to the sidereal clock at Greenwich, to correct for the effect of variations in the atmospheric pressure on the motion of the pendulum. This clock is placed in a basement which is kept at a nearly uniform temperature, an important condition, which has contributed to make its performance very far superior to that of any other clock hitherto constructed, and fully equal to the requirements of the methods of observation now in use. With instruments such as have just been described, regular observations of the sun, moon, and planets, and of fundamental stars, are made at Greenwich, Paris, Washington, and Oxford, supplemented at the first-named observatory by extra-meridian observations of the moon with a massive altazimuth, which can be employed when the moon is too near new moon to be seen on the meridian in full daylight, and which is in fact used to secure an observation on every night when the moon is visible. The observations of stars at these four observatories are directed to the most accurate determination of the places of a limited number, and the deduction of their proper motions by comparison with the results obtained by Bradley, Piazzi (with an altazimuth by Ramsden at Palermo), and Groombridge; but at other observatories differential or zone observations of large numbers of stars have been made, with the object of making a complete and tolerably accurate survey of the heavens, the rhomb or ring micrometer being used for this purpose. Among those who have devoted themselves to this work may be mentioned Lacaille at the Cape of Good Hope, Lalande at Paris, Bessel at Königsberg, and Argelander at Bonn. These

zone-observations are now being repeated with the transit-circle at a number of observatories, associated together for the purpose of getting far more accurate places than was possible with the equatorial. A large number of observatories, chiefly in Germany and America, are devoted to a very different class of observations—viz., differential observations with the Equatorial (q.v.) of comets and small planets as referred to comparison-stars, and the search for such objects; whilst at other observatories, among which that of Pulkowa may be mentioned, the measurement of double stars with the micrometer is laid down as the chief object. Of late years two new subjects have been introduced in the routine of observatory work—photography and spectroscopy. The former was carried on for many years at Kew Observatory under Mr De La Rue's auspices, and at his private observatory at Cranford, and the work is now being continued at Greenwich; the latter has been taken up at a number of Italian observatories, and particularly at Rome by P. Secchi, and it now forms part of the regular system at Greenwich; whilst the observatories at Paris, Berlin, and Vienna are equipped for these physical observations, and in America and Australia they are vigorously carried on at several observatories—Melbourne, in particular, being provided with a four-foot equatorial reflector for this purpose, as well as for the examination of nebulae. The most important work of an observatory, however, consists, not in making observations which are easily multiplied, but in reducing and publishing them—a task of far greater labour, and requiring far higher qualifications. However various may be the observations, the method of eliminating their errors is the same in all cases, and similar mathematical considerations apply to their reduction, whether they be meridian observations, micrometer measures, measures of photographs, or spectroscopic observations; and it is when such treatment is required in any inquiry that it should be undertaken at a public observatory, where this rigorous method will be applied.

The work of private observatories hardly admits of being specified, though its general character has already been indicated; it may suffice to mention the observations of double stars and nebulae by the two Herschels, Groombridge's catalogue of circumpolar stars, Smyth's double-star measures, Carrington's Redhill catalogue and solar observations, the nebular observations of Lord Rosse and Mr Lassell, De La Rue's long series of photographs, and the spectroscopic observations of Huggins and Lockyer.

In addition to regular astronomical observations of all kinds, national observatories are usually charged with the distribution of time signals, and the rating of chronometers for the navy—matters of great practical importance, especially in this country, where Greenwich time is communicated directly by telegraph to more than six hundred towns.

OBSIDIAN, a mineral accurately described by Pliny under the name which it still bears. It is a true kind of native glass, composed of silica (from 70 to 80 per cent.), alumina, lime, soda, potash, and oxide of iron. It is hard and brittle, with remarkably vitreous lustre, and perfectly conchoidal fracture, the edges of the fractures very sharp and cutting like glass. It varies from semitransparency to translucency only on the edges. It is often black, or very dark gray; sometimes green, red, brown, striped, or spotted; and sometimes *chatoyant* or *aventurine*. It occurs in volcanic situations, and often in close connection with pumice in roundish compact pieces, in grains, and in fibres. It is capable of being polished, but is apt to break in the process. It is made into boxes, buttons, ear-drops, and other ornamental articles; and before

the uses of the metals were well known, it was employed, in different parts of the world, for making arrow and spear heads, knives, &c. It is found in Iceland, the Lipari Isles, Vesuvius, Sardinia, Hungary, Spain, Teneriffe, Mexico, South America, Madagascar, Siberia, &c. Black O. was used by the ancients for making mirrors, and for this purpose was brought to Rome from Ethiopia. It was used for the same purpose in Peru and Mexico. Mirrors of Black O. are indeed still employed by artists. Chatoyant or Avantine O. is very beautiful when cut and polished, and ornaments made of it are sold at a comparatively high price.

O'VERSE, or **FACE**, the side of a coin or medal which contains the principal device or inscription, the other side being in contradistinction called the Reverse. See **NUMISMATICS**.

OCCAM, **WILLIAM OF**, surnamed *Doctor Singularis et Invincibilis*, a famous schoolman, was born in England, at the village of Ockam, in the county of Surrey, about the year 1270. We do not possess any precise or satisfactory knowledge of his early life. He is said to have been educated at Merton College, Oxford, and to have held several benefices in his native country, but soon after resigned them on entering the Franciscan order. Early in the 14th c., it is supposed he proceeded to Paris, where he attended the lectures of Duns Scotus, of whose philosophy he was afterwards the most formidable opponent. Here he soon became prominent by the boldness of his ecclesiastical views. Philippe, le Bel, king of France, having forbidden Pope Boniface VIII. to levy contributions in his dominions, the latter, by way of retaliation, excommunicated him. O. rushed to the defence of the monarch, and in his *Disputatio inter Clericum et Militem, super Potestate Prelatis Ecclesie atque Principibus Terrarum Commissa*, denies that the popes have any authority in temporal affairs, and boldly declares that all who favoured such a doctrine ought to be expelled from the church as heretics. Meanwhile, from being a listener, he had become a lecturer in philosophy. The system which he advocated—for he was not properly its originator—is known by the name of *Nominalism* (q. v.), but it had never before received so rigorously logical and rational a treatment; hence his epithet of *Invincibilis*. The work in which his views are set forth is entitled *Expositio Aurea, et admodum utilis super totam Artem Veterem*. It contains a series of commentaries upon the *Isagoge* of Porphyry, and on the *Categories* and *Interpretation* of Aristotle, with a special treatise headed *Tractatus Communitatum Porphyrii*, and a theological opusculum on Predestination. It is intended as a demolition of the moderns—i. e., the scholastics—and shews that in their method they have completely departed from the principles and methods of the great Stagyrte, for whom, like every sound and solid thinker, he shews the deepest respect and admiration. About 1320 or 1321, he again plunged into ecclesiastical controversy. A certain Narbonne priest, having affirmed that Jesus Christ and his apostles held everything in common, and that every ecclesiastical possession is a modern abuse, was pounced upon by the inquisitors, and defended by a certain Berenger Talon, a Franciscan monk of Perpignan. But Berenger's defence of apostolical poverty was naturally enough very disagreeable to the pope, John XXII., who therefore condemned it. Berenger was, however, vigorously supported by his order, and among others by Michael de Cesena, the general-superior, Bonagratia of Bergamo, and William of Occam, who attacked the pope with great vehemence and trenchant logic. Shortly after

they were arrested as favourers of heresy, and imprisoned in Avignon. But while their trial was proceeding, Michael de Cesena and O., knowing what little mercy or justice they had to expect from their accusers and judges, made their escape to the Mediterranean, and were received at a little distance off shore on board a galley of Ludwig, king of Bavaria, the patron of the Franciscan anti-pope, Peter of Corbaras, and one of the most powerful sovereigns in Europe. The remainder of O.'s life was spent at Munich, where, safe from the machinations of his enemies, he continued to assail at once the errors of papistry in religion, and of realism in philosophy. He died 7th April 1347. It is impossible to praise O. too highly. He was the first logician, and the most rational philosopher among the whole body of schoolmen. We are often reminded by his clear and vigorous common sense and wholesome incredulity, that he was the countryman of Locke and Hobbes, and that he came of a people ever noted for the solidity of their understanding. Besides the works already mentioned, O.'s principal writings are—*Dialogus in tres Partes distinctus, quarum prima de Hæreticis, secunda de Erroribus Joannis XXII., tertia de Potestate Papæ, Conciliorum et Imperatoris; Opus Nonaginta Dierum contra Errores Joannis XXII.; Compendium Errorum Joannis Papæ XXII.; Decisiones Octo Quæstionum de Potestate summi Pontificis; Super Quatuor Libros Sententiarum Subtilissimæ Quæstiones earumque Decisiones* (based on Peter the Lombard's famous *Sententia*, and containing nearly the entire theology of Occam. These *Decisiones* were long almost as renowned as the *Sententia*, which gave them birth); *Antiloquium Theologicum; Summa Logices ad Adamum; et Major Summa Logices*.—See Luke Wadding's *Scriptores Ordinis Minorum* (1650); Hauréau's *De la Philosophie Scholastique* (1848; new ed. 1873); and the works of Kaulich, Stüeckl, Prantl, and Erdmann.

OCCASIONALISM, or the doctrine of **OCCASIONAL CAUSES** (see **CAUSE**), is the name given to the philosophical system devised by Descartes and his school, for the purpose of explaining the action of mind upon matter, or, to speak more correctly, the combined, or at least the synchronous action of both. It is a palpable fact that certain actions or modifications of the body are accompanied by corresponding acts of mind, and *vice versa*. This fact, although it presents no difficulty to the popular conception, according to which each is supposed to act directly upon the other—body upon mind, and mind upon body—has long furnished to philosophers a subject of much speculation. But on the other hand, it is difficult to conceive the possibility of any direct mutual interaction of substances so dissimilar, or rather so disparate. And more than one system has been devised for the explanation of the problem, as to the relations which subsist between the mind and the body, in reference to those operations, which are clearly attributable to them both. According to Descartes and the Occasionalists, the action of the mind is not, and cannot be the cause of the corresponding action of the body. But they hold that whenever any action of the mind takes place, God directly produces, in connection with it, and by reason of it, a corresponding action of the body; and in like manner conversely, they explain the coincident or synchronous actions of the body and the mind. It was in opposition to this view that Leibnitz, believing the Cartesian system to be open to nearly equal difficulties with that of the direct action, devised his system of *Pre-established Harmony*. See **LEIBNITZ**. His real objection to the Occasionalist hypothesis is, that it supposed a

perpetual action of God upon creatures, and, in fact, is but a modification of the system of 'direct assistance.'

OCCULTATIONS (Lat. *occultatio*, a concealment) are neither more nor less than 'eclipses;' but the latter term is confined by usage to the obscuration of the sun by the moon, and of the moon by the earth's shadow, while the former is restricted to the eclipses of stars or planets by the moon. Occultations are phenomena of frequent occurrence; they are confined to a belt of the heavens about $10^{\circ} 17\frac{1}{2}'$ wide, situated parallel to, and on both sides of the equinoctial, and extending to equal distances north and south of it, being the belt within which the moon's orbit lies. These phenomena serve as data for the measurement of the moon's parallax; and they are also occasionally employed in the calculation of longitudes. As the moon moves in her orbit from west to east, the occultation of a star is made at the moon's eastern limb, and the star emerges on the western limb. When a star is occulted by the dark limb of the moon (a phenomenon which can only occur between new moon and full moon), it appears to an observer as if it were suddenly extinguished, and this appearance is most deceptive when the moon is only a few days old. When an occultation occurs between full moon and new moon, the reappearance of the star at the outer edge of the dark limb produces an equally startling effect. 'It has often been remarked,' says Herschel, 'that when a star is being occulted by the moon, it appears to advance actually upon and within the edge of the disc before it disappears, and that sometimes to a considerable depth.' This phenomenon he considers to be an optical illusion, though he admits the possibility of its being caused by the existence of deep fissures in the moon's substance. Occultations of stars by planets and their satellites are of rarer occurrence than lunar occultations, and still more unfrequent are the occultations of one planet by another. Occultations are calculated in the same way as eclipses, but the calculation is simplified in the case of the fixed stars, on account of their having neither sensible motion, semi-diameter, nor parallax.

OCEAN, a term which, like **SEA**, in its general acceptance, denotes the body of salt water that separates continent from continent, and is the receptacle for the waters of rivers. The surface of the ocean is about three-fifths of the whole surface of the earth. Although no portion of it is completely detached from the rest, the intervening continents and islands mark it off into divisions, which geographers have distinguished by special names: the *Atlantic Ocean* (q. v.), between America and Europe and Africa; the *Pacific Ocean* (q. v.), between America and Asia; the *Indian Ocean* (q. v.), lying south of Asia, and limited on the east and west by Australasia and South Africa; the *Arctic Ocean* (q. v.), surrounding the north pole; and the *Antarctic Ocean* (q. v.), surrounding the south pole. The general features and characteristics of the ocean will be described under **SEA**.

OCEANIA, the name given to the fifth division of the globe, comprising all the islands which intervene between the south-eastern shores of the continent of Asia and the western shores of the American continent. It naturally divides itself into three great sections—Malay Archipelago (q. v.), Australasia (q. v.) or Melanesia, and Polynesia (q. v.).

OCELOT, the name of several species of *Felida*, natives of the tropical parts of South America, allied to the leopard by flexibility of body, length of tail, and other characters, but of much smaller

size. They are usually included in the genus *Leopardus* by those who divide the *Felidae* into a number of genera. They are inhabitants of forests, and very expert in climbing trees. Their prey consists in great part of birds. They are beautifully marked and coloured. The best known species, or **COMMON O.** (*Felis pardalis*), a native of the warm parts of America, from Mexico to Brazil, is

Ocelot (*Felis pardalis*).

from two feet nine inches to four feet long, exclusive of the tail, which is from eleven to fifteen inches, and nearly of uniform thickness. The ears are thin, short, and pointed. The muzzle is rather elongated. The colours vary considerably, but the ground tint is always a rich red or tawny colour, blending finely with the dark brown on the margins of the open spots, of which there are chains along the sides; the head, neck, and legs being also variously spotted or barred with dark brown or black. The O. is easily tamed, and is very gentle and playful, but excessively mischievous. It may be fed on porridge and milk, or other such food, and is said to be then more gentle than if permitted to indulge in carnivorous appetites.—Very similar to the **COMMON O.** are several other American species, as the **LINKED O.** (*F. catenata*), the **LONG-TAILED O.** (*F. macrourus*), the **CHATI** (*F. mitis*), &c. The similarity extends to habits and disposition, as well as form.

O'CHIL HILLS, a hilly range in Scotland, occupying parts of the counties of Perth, Clackmannan, Stirling, Kinross, and Fife, and extending from the vicinity of Stirling north-east to the Firth of Tay. The range is 24 miles in length, and about 12 miles in breadth. The highest summit is Bencleugh (2352 feet), near the south-west extremity. The hills, which are formed chiefly of greenstone and basalt, contain silver, copper, and iron ores, and afford excellent pasturage.

OCHNA'CEÆ, a natural order of exogenous plants, containing not quite 100 known species, natives of tropical and subtropical countries. Some of them are trees, most of them under-shrubs; all are remarkable for their smoothness in all parts. Bitter and tonic qualities prevail in this order, and some species are medicinally used in their native countries. The seeds of *Gomphia jabotipitia* yield an oil, which is used in salads in the West Indies and South America.

O'CHRES, the name usually applied to clays coloured with the oxides of iron in various proportions, giving to the clay a lighter or deeper colour. Strictly speaking, the term belongs only to a combination of peroxide of iron with water. From many mines large quantities of water charged with ferruginous mud are being continually pumped up, and from this water the coloured mud or ochre settles. In this way large quantities are procured from the tin mines of Cornwall, and the lead and copper mines of North Wales and the Isle of Man. Ochres occur also ready formed, in beds several feet

thick, in the various geological formations, and are occasionally worked, as at Shotover Hill, Oxford, in Holland, and many other places in Europe and America. Very remarkable beds are worked in Canada. The ochres so obtained are either calcined for use or not, according to the tint wanted. The operation adds much to the depth of colour, by increasing the degree of oxidation of the contained iron. The most remarkable varieties of ochre are the Siena Earth (Terra di Siena) from Italy; the so-called red chalk, with which sheep are marked; Dutch Ochre; Armenian Bole or Lemnian Earth; Italian Rouge, and Bitry Ochre. They vary in colour from an Isabelline yellow, through almost every shade of brown, up to a tolerably good red. The finest kinds are used by painters, the coarsest by carpenters for marking out their work, by farmers for marking cattle, &c.

O'CHRO. See **HIBISCUS**.

OCKMULGEE, a river in Georgia, U. S., which rises in the northern centre of the state by three branches, and after a course of 200 miles south-east, joins the Oconee, to form the Altamaha. It is navigable to Macon, 130 miles above its mouth.

OCONEE, a river of Georgia, U. S., rises in the north-east part of the state, and flows southerly 250 miles, where it unites with the Ockmulgee to form the Altamaha; it is navigable to Milledgeville, 100 miles.

O'CONNELL, DANIEL, eldest son of Mr Morgan O'Connell of Darrynane, near Cahirciveen, in the county of Kerry, Ireland, was born August 9, 1775. His family was ancient, but straitened in circumstances. O'C. received his first education from a hedge-schoolmaster, and after a further training under a Catholic priest in the county of Cork, was sent in 1790 to the English College at St Omer. His school reputation was very high; but he was driven home prematurely by the outbreak of the Revolution, and in 1794, entered as a law-student at Lincoln's Inn. In 1798, he was called to the bar; and it was the boast of his later career as an advocate of the Repeal of the Union with England, that his first public speech was delivered at a meeting in Dublin, convened for the purpose of protesting against that projected measure. He devoted himself assiduously, however, to the practice of his profession, in which he rose steadily. By degrees, the Roman Catholic party having begun to rally from the prostration into which they had been thrown through the rebellion of 1798 and its consequences, O'C. was drawn into public political life. In all the meetings of his co-religionists for the prosecution of their claims, he took a part, and his unquestioned ability soon made him a leader. He was an active member of all the successive associations which, under the various names of 'Catholic Board,' 'Catholic Committee,' 'Catholic Association,' &c., were organised for the purpose of procuring the repeal of the civil disabilities of the Catholic body. Of the Catholic Association he was himself the originator; and although his supremacy in its councils was occasionally challenged by some aspiring associates, he continued all but supreme down to its final dissolution. By means of this association, and the 'Catholic Rent' which it was enabled to raise, he created so formidable an organisation throughout Ireland, that it gradually became apparent that the desired measure of relief could no longer be safely withheld; and the crisis was precipitated by the bold expedient adopted by O'C., of procuring himself to be elected member of parliament for Clare in 1828, notwithstanding his well-known legal incapacity to serve in parliament, in consequence of his being obliged to refuse the

prescribed oaths of abjuration and supremacy, which then formed the ground of the exclusion of Roman Catholics from the legislature. This decisive step towards the settlement of the question, although it failed to procure for O'C. admission to parliament, led to discussions within the House, and to agitations outside, so formidable, that in the beginning of the year 1829, the Duke of Wellington and Sir Robert Peel found it expedient to give way; and, deserting their former party, they introduced and carried through, in the spring of that year, the well-known measure of Catholic Emancipation. O'C. was at once re-elected, and took his seat for Clare, and from that date until his death continued to sit in parliament. He was elected for his native county in 1830, for the city of Dublin in 1836, for the town of Kilkenny in 1836 (having been unseated for Dublin on petition), for Dublin again in 1837, and for the county of Cork in 1841. During all these years, having entirely relinquished his practice for the purpose of devoting himself to public affairs, he received, by means of an organised annual subsidy, a large yearly income from the voluntary contributions of the people, by whom he was idolised as their 'Liberator;' and who joined with him in all the successive agitations against the act of Union, against the Protestant Church establishment, and in favour of reform, in which he engaged. In the progress of more than one of these political agitations, his associations were suppressed by the government; and the agitation for a Repeal of the Union, recommenced in 1841, and carried on by 'monster meetings' throughout Ireland, at which O'C. himself was the chief speaker, assumed proportions so formidable, that he, in common with several others, was indicted for a seditious conspiracy, and after a long and memorable trial, was convicted, and sentenced to a year's imprisonment, with a fine of £2000. This judgment was reversed by the House of Lords; and O'C., on his discharge, resumed his career; but his health had suffered from confinement, and still more from dissensions and opposition in the councils of his party; and as, on the return of the Whigs to power in 1846, he consented to support their government, the malcontents of the Repeal Association openly separated from him, and a bitter feud between 'Young' and 'Old' Ireland ensued. In this quarrel, O'C. steadfastly maintained his favourite precept of 'moral force,' and was supported by the great body of the Catholic bishops and clergy; but his health gave way in the struggle. He was ordered to try a milder climate; and on his journey to Rome in the spring of 1847, he was suddenly seized with paralysis, and died at Genoa on the 15th May of that year. His eminence as a public speaker, and especially as a master of popular eloquence, is universally admitted. Into the controversies as to his public and political character, it is not our place to enter here. His speeches unfortunately were for the most part extempore, and exist but in the reports (uncorrected by himself) taken at the time. He published but a single volume, *A Memoir of Ireland, Native and Saxon*, and a few pamphlets; the most important of which, as illustrating his personal history and character, is *A Letter to the Earl of Shrewsbury*.—See *Life and Times of Daniel O'Connell*, by his son, John O'Connell; also *Recollections of Daniel O'Connell*, by John O'Neill Daniel; Fagan's *Life of Daniel O'Connell*; and *The Liberator*, by L. F. Cusack (1872).

OCTAGON, a plane closed figure of eight sides. When the sides are equal, and also the angles, the figure is called a 'regular octagon;' in this case, each angle is 135°, or equal to three half right angles. If the alternate corners of a regular octagon be joined, a square is constructed; and as the angle contained

between the sides of the square and of the octagon is one-fourth of a right angle, the octagon may easily be constructed from the square as a basis.

OCTAHEDRON (Gr. *okto*, eight, *hedra*, base) is a solid figure bounded by eight triangles, and having twelve edges and six angles. A regular octahedron has its eight triangular faces all equilateral, and may, for convenience, be defined as a figure composed of two equal and similar square pyramids with equilateral triangles for their sides placed base to base. This solid is symmetrical round any angle, and is one of Plato's five regular solids. The octahedron appears in nature as one of the forms of crystals of sulphur.

Octahedron.

OCTAVE (Lat. *octavus*, eighth), the interval between any musical note and its most perfect concord, which is double its pitch, and occupies the position of the eighth note from it on the diatonic scale. The name octave is often given to the eighth note itself as well as to the interval. There is between a note and its octave a far closer relation than between any other two notes; they go together almost as one musical sound. In combination, they are hardly distinguishable from one another, and their harmonics agree invariably, a coincidence which occurs in the case of no other interval.

OCTAVIA, the sister of the Roman emperor Augustus, and wife of Mark Antony. She was distinguished for her beauty, her noble disposition, and womanly virtues. Her first husband was C. Marcellus, to whom she was married 50 B.C. He died 41 B.C., shortly after which she consented to marry Antony, to make secure the reconciliation between him and her brother. The event was hailed with joy by all classes. In a few years, Antony became tired of his gentle and virtuous spouse, and forsook her for Cleopatra. When the Parthian War broke out, O. wanted to accompany her husband, and actually went as far as Coryra, whence Antony sent her home, that she might not interrupt his guilty intercourse with the Egyptian queen. In 35 B.C., O. made an effort to rescue him from a degradation that was indifferent even to the honour of the Roman arms, and sailed from Italy with reinforcements; but a message reached her at Athens ordering her to return home. She proudly obeyed, but, with a magnanimity that reminds us of the Roman character in earlier and better days, she forwarded the supports to her husband. Her brother, Octavian, was indignant at the treatment she received, and would have had her quit her husband's house, and come and live with him; but she refused. In 32 B.C., war, long inevitable, broke out between Antony and Octavian; and the former crowned his insults by sending O. a bill of divorce. But no injury was too great to be forgiven by this 'patient Grisel' of the ancient world; and after her husband's death, she brought up with maternal care not only her own children, but also Cleopatra's bastards. Her death took place 11 B.C.

OCTOBER (Lat. *octo*, eight) was the eighth month of the so-called 'year of Romulus,' but became the tenth when (according to tradition) Numa changed the commencement of the year to the first of January, though it retained its original name. It has since maintained its position as the tenth month of the year, and has 31 days. October preserved its ancient name notwithstanding the attempts made by the Roman senate, and the emperors Commodus and Domitian, who substituted for a time the terms *Faustinus*, *Invictus*,

Domitianus. Many Roman and Greek festivals fell to be celebrated in this month, the most remarkable of which was the sacrifice at Rome of a horse (which was called *October*) to the god Mars. The other festivals were chiefly bacchanalian. Among the Saxons, it was styled *Wyn moneth* or the wine month.

OCTOPODA (Gr. eight-footed), a section of dibranchiate cephalopods (see *CEPHALOPODA*), having the body in general very short, the head very distinct; eight arms, not very unequal, furnished with simple suckers; with or without a shelly covering. To this section belong Argonauts, Poulpes, &c.

OCTOPUS. See *POULPE*.

OCTOSTYLE, the name given in classic architecture to a portico composed of eight columns in front.

OCTROI (Lat. *auctoritas*, authority), a term which originally meant any ordinance authorised by the sovereign, and thence came to be restrictively applied to a toll or tax in kind levied from a very early period in France, and other countries of Northern Europe, on articles of food which passed the barrier or entrance of a town. The right to levy this toll was often delegated to subjects, and in order to increase its amount, a device was resorted to of raising the weight of the pound in which the octroi was taken. The large pound, an ounce heavier than that in ordinary use, was called the *livre d'octroi*, whence the expression *pound troy*. The octroi came eventually to be levied in money, and was abolished in France at the Revolution. In 1798, it was re-established, under the pretext that it was required for purposes of charity, and called the *octroi de bienfaisance*, and it has been reorganised in 1816, 1842, and 1852. Of the octroi duty which is at present levied at the gates of the French towns, one-tenth goes to the national treasury, and the rest to local expenses. The octroi officers are entitled to search all carriages and individuals entering the gates of a town. From the octrois of Paris, government derived, a few years ago, a revenue of 56 million francs. In 1860, the Belgian government acquired popularity by abolishing the octroi.

The epithet *octroyé* is applied by continental politicians to a constitution granted by a prince, in contradistinction to one which is the result of a pact between the sovereign and the representatives of the people. Any public company possessing an authorised monopoly like that held by the East India Company, is said to be *octroyé*.

OD (from the same root as *Odin*, and supposed to mean all-pervading), the name given by Baron Reichenbach (q.v.) to a peculiar physical force which he thought he had discovered. This force, according to him, pervades all nature, and manifests itself as a flickering flame or luminous appearance at the poles of magnets, at the poles of crystals, and wherever chemical action is going on. This would account for the luminous figures said to be sometimes seen over recent graves. The od force has positive and negative poles, like magnetism. The human body is od-positive on the left side, and od-negative on the right. Certain persons, called 'sensitives,' can see the odic radiation like a luminous vapour in the dark, and can feel it by the touch like a breath. As the meeting of like odic poles causes a disagreeable sensation, while the pairing of unlike poles causes a pleasant sensation, we have thus a sufficient cause for those likings and antipathies hitherto held unaccountable. Some sensitive persons cannot sleep on their left side (in the northern hemisphere), because the north pole of the earth, which is od-negative, affects unpleasantly the od-negative left side. All motion generates od;

why, then, may not a stream running underground affect a sensitive water-finder, so that the divining-rod in his or her hand shall move without, it may be, any conscious effort of will? All the phenomena of mesmerism are ascribed to the workings of this od-force. Reichenbach does not pretend to have had the evidence of his own senses for any of those manifestations of his assumed od-force; the whole theory rests on the revelations made to him by 'sensitives.' It may be added, that few if any really scientific men have any belief in the existence of such a force.—Those curious in such matters are referred for the details of the subject to Reichenbach's large work, translated by Dr Ashburner, *The Dynamics of Magnetism*, or to his *Odisch-Magnetische Briefe*. And see the *Transactions of the Psychical Research Society* (1883).

O'DAL or UDAL RIGHT (Celtic *od*, property), a tenure of land which was absolute, and not dependent on a superior, and prevailed throughout Northern Europe before the rise of feudalism. It was founded on the tie of blood which connected freeman with freeman, and not on the tie of service. It was the policy of the sovereign authority everywhere to make it advantageous for the freemen to exchange the odal tie for the tie of service—a change which paved the way for the feudal system. The odallers of Orkney were allowed to retain or resume their ancient privileges, on paying a large contribution to the erection of St Magnus's Cathedral at Kirkwall; and the Odal tenure prevails to this day to a large extent in the Orkney and Shetland Islands, the right to land being completed without writing by undisturbed possession proved by witnesses before an inquest.

ODD-FELLOWS, the name assumed by one of the most extensive self-governed provident associations in the world. The institution was originated in Manchester in 1812, although isolated 'lodges' had existed in various parts of the country for some time previously. These latter were generally secret fraternities, humble imitations of Freemasonry—adopting a similar system of initiatory rites, phraseology, and organisation—instituted for social and convivial purposes, and only occasionally extending charitable assistance to members. On its institution in Manchester, the main purpose of Odd-fellowship was declared by its laws to be, 'to render assistance to every brother who may apply through sickness, distress, or otherwise, if he be well attached to the Queen and government, and faithful to the order;' and this continues to be the basis of all its operations. It still, however, retains some of the characteristics of Freemasonry, in possessing pass-words and peculiar 'grips,' whereby members can recognise one another. The headquarters of the society are at Manchester, where the Grand Master and Board of Directors meet quarterly to hear appeals, and transact the general business of the order. In January 1852, the total number of members was 224,441; in January 1882, the number was 547,909. The lodges number 4153, spread over 452 districts; the annual income being about £780,000, with considerably less expenditure. Should any lodge fail to meet its legitimate obligations, the district becomes liable; failing the district, the responsibility falls upon the entire Unity. The order is widely spread over the whole of England and Scotland. It exists independently in America (where there are near 420,000 members of the separated association), Australia, New Zealand, and the West Indies; but there are 'lodges' in Philadelphia, New York, in all the British colonies, and one in Constantinople (originated in 1862), which are affiliated

to and in connection with the Manchester Board. These wide-spread ramifications of this society enable emigrant members to be at once received into fellowship in those countries. In the American states, Odd-fellowship is said to exercise considerable political influence. A quarterly periodical, called the *Odd-fellows' Magazine*, devoted to its interests, was for a time published. In an early number of this publication, an Odd-fellow is described as 'like a fox for cunning, a dove for tameness, a lamb for innocence, a lion for boldness, a bee for industry, and a sheep for usefulness.'

ODE (Gr. a song) originally meant any lyrical piece adapted to be sung. In the modern use of the word, odes are distinguished from songs by not being necessarily in a form to be sung, and by embodying loftier conceptions and more intense and passionate emotions. The language of the ode is therefore abrupt, concise, and energetic; and the highest art of the poet is called into requisition in adapting the metres and cadences to the varying thoughts and emotions. Hence the changes of metre and versification that occur in many odes. The rapt state of inspiration that gives birth to the ode, leads the poet to conceive all nature as animated and conscious, and, instead of speaking about persons and objects, to address them as present. See Gosse's *English Odes* (1881).

Among the highest examples of the ode are the *Song of Moses* and several of the psalms. Dryden's *Alexander's Feast* is reckoned one of the first odes in the English language. We may mention, as additional specimens, Gray's *Bard*, Collins's *Ode to the Passions*, Burns's *Scots wha ha'e*, Coleridge's *Ode to the Departing Year and Dejection*, Shelley's *Ode to the Skylark*, and Wordsworth's *Ode on the Recollections of Immortality in Childhood*.

ODENSEE (anciently known as Odin's-Ey, or Odin's Oe (i. e., Odin's Island), the chief town of the Danish island of Fünen, and the oldest city of the kingdom, is situated in the amt or district of the same name, in 55° 25' N. lat., and 10° 20' E. long. Pop. (1880) 20,804. O., which is the seat of the governor of the island and the see of a bishop, has a gymnasium, several literary societies, and is an active, thriving provincial town. A bishopric was founded here in 988, prior to which time O. bore the reputation of being the first city established by Odin and his followers. The cathedral, founded in 1086 by St Knud, whose remains, like those of several of the early Danish kings, were deposited here, is a fine specimen of the early simple Gothic style. The lay convent or college for ladies contains an extensive library, furnished with copies of all printed Danish works. At O., a diet was held in 1527, in which the Reformed or Lutheran doctrines were declared to be the established creed of Denmark, and equality of rights was granted to Protestants; while another diet held there in 1539 promulgated the laws regulating the affairs of the Reformed Church.

O'DENWALD. See HESSE-DARMSTADT.

ODER (Lat. *Viadrus*, Slavon. *Vjodr*), one of the principal rivers of Germany, rises in the Leselberg on the table-land of Moravia, more than 1000 feet above the level of the sea, and enters Prussian Silesia at Odersberg, after a course of some 60 miles. After traversing Brandenburg in a north-west direction, it crosses Pomerania, and empties itself into the Stettiner Haff, from whence it passes into the Baltic by the triple arms of the Dievenow, Peene, and Swine, which enclose the islands of Wollin and Usedom. The O. has a course of more than 500 miles, and a river-basin of 50,000 square miles. The rapid flow of this river, induced by its very considerable fall, is accelerated by the affluence

of several important mountain-streams, and thus contributes, together with the silting at the embouchures of these streams, to render the navigation difficult; great expense and labour being, moreover, necessary to keep the embankments in order, and prevent the overflowing of the river. The O. has numerous secondary streams, the most important of which are the Oppa, Neisse, Ohlau, Kłodnitz, Bartsch, Warthe, and the Inna; and is connected with the Havel and thence with the Elbe by the Finow Canal, and with the Spree by the Friedrich-Wilhelms Canal. The chief trading port of the O. is Swinemünde, which constitutes an important centre for the transfer of colonial and other foreign goods to Northern Germany and Poland. At Ratibor, 17 miles below Oderberg, the river becomes navigable, and is upwards of 100 feet in breadth; at Oppeln, in Prussian Silesia, it has a breadth of 238 feet. As a boundary river, it is of considerable importance in a military point of view, and is well defended by the fortresses of Kosel, Grossglogau, Küstrin, and Stettin.

ODESSA, an important seaport and commercial city of South Russia, in the government of Kherson, stands on an acclivity sloping to the shore, on the north-west coast of the Black Sea, 32 miles north-east of the mouth of the Dniester. Lat. 46° 29' N., long. 30° 44' E. The harbour is formed by two large moles defended by strong works, and is capable of containing 200 vessels. The bay is deep enough even close in shore to admit the approach of the largest men-of-war, and is frozen only in the severest winters, and then only for a short time. The promenade along the face of the cliff, descending to the shore by a broad stone stair of 204 steps, is the favourite walk of the inhabitants. Here also stands the monument of the Duc de Richelieu, to whom in great part the town is indebted for its prosperity. In the pedestal of the monument is preserved the ball by which he was shot during the bombardment of the town by the allied fleet in 1854. The university of O., founded in 1865, had, in 1877, 43 professors and 252 students; and the library possessed over 150,000 volumes. The city contains many fine edifices, as the Cathedral of St Nicholas, the Admiralty, the Custom-house, &c. Owing to the intensity of the heat in summer (rising occasionally to 120°), and the dryness of the soil, vegetation in the vicinity of O. is very poor. In the neighbourhood are quarries of soft stone, which is used for building purposes in O. and in the surrounding towns. One of the great deficiencies of O. used to be its want of good water; but works for securing an ample supply from the Dniester were completed in 1873. Gas was first used in O. in 1861; and the theatre, the hotels, and all the larger houses now use this handiest of the artificial lights. A railway, opened in 1872, has added enormously to the commercial success and importance of O., as it connects it, and of course Kherson, with the governments north and east of it in Russia. Tramways have been laid, and new quays and custom-houses erected on ground reclaimed from the sea. The estimated value of the various quantities of grain, wool, hides, tallow, and other articles of export for the year 1879 (the best year for more than 20 years) was £8,140,480; the number of vessels which entered the port in the same year was 1471, of which 552 were English. O. is now also an important manufacturing town, tobacco, candles, ropes, and cast-iron goods being amongst the more notable products. Between 1870 and 1880, the annual value of manufactures was about £2,300,000. Pop. of O. (1882) 217,000.

In ancient times, O. (Gr. *Odessus*) was inhabited by a Greek colony, and later by Tartar tribes. In

the beginning of the 15th c., the Turks constructed a fortress here, which was taken by the Russians in 1789. In 1793, a Russian fortress was built here, and became the nucleus of a town and port, which two years after received the name of Odessa. The Duc de Richelieu, a French emigrant in the Russian service, was appointed governor here in 1803, and during the eleven years of his wise administration, the town prospered rapidly. Since 1823, the city has formed part of the general governorship of South Russia; is the seat of its administration, and is the residence of the governor-general and of an archbishop. The advantageous commercial position of the city, and the privileges granted to it by government, but chiefly the privileges of a free port between 1817 and 1858 (in place of which it now receives an annual subsidy), have developed this city from a mere Turkish fortress into the chief commercial town of the Russian empire after St Petersburg and Riga. On the outbreak of the Crimean War, in 1854, a British steamer went to O. to bring away the British consul, and was fired upon by the batteries of the city. Twelve English war-ships attacked O., and in a few hours destroyed the fortifications, and took a number of Russian vessels.

ODEYPOOR, OODYPORE, or UDAIPUR, the name of several territories in India.—1. The principal is a Rajpoot state, also called Meywar; area, 12,600 sq. m., and pop. (1881) 1,494,220. The capital, Oodeypur, stands on one of the most picturesque sites in India, has a noble palace, and a pop. (1881) of 35,000.—2. A tributary state in Chota Nagpore, with an area of 1000 sq. m.; pop. 30,000.—3. Chota O. is a tributary state in Gujerat; area, 650 m.; pop. 70,000.

ODIN, the chief god of Northern Mythology. According to the sagas, O. and his brothers, Vile and Ve, the sons of Boer, or the first-born, slew Ymer or Chaos, and from his body created the world, converting his flesh into dry land; his blood, which at first occasioned a flood, into the sea; his bones into mountains; his skull into the vault of heaven; and his brows into the spot known as *Midgaard*, the middle part of the earth, intended for the habitation of the sons of men. O., as the highest of the gods, the *Alfader*, rules heaven and earth, and is omniscient. As ruler of heaven, his seat is Valaskjalf, from whence his two black ravens, Huginn (Thought) and Muninn (Memory), fly daily forth to gather tidings of all that is being done throughout the world. As god of war, he holds his court in Valhalla, whither come all brave warriors after death to revel in the tumultuous joys in which they took most pleasure while on earth. His greatest treasures are his eight-footed steed Sleipner, his spear Gungner, and his ring Draupner. As the concentration and source of all greatness, excellence, and activity, O. bears numerous different names. By drinking from Mimir's fountain, he became the wisest of gods and men, but he purchased the distinction at the cost of one eye. He is the greatest of sorcerers, and imparts a knowledge of his wondrous arts to his favourites. Frigga is his queen, and the mother of Baldur, the Scandinavian Apollo; but he has other wives and favourites, and a numerous progeny of sons and daughters. Although the worship of O. extended over all the Scandinavian lands, it found its most zealous followers in Denmark, where he still rides abroad as the wild huntsman, rushing over land and water in the storm-beaten skies of winter.

The historical interpretation of this myth, as given by Snorre Sturleson, the compiler of the *Heimskringla*, or *Chronicles of the Kings of Norway* prior to the introduction of Christianity, and

followed in recent times by the historian Suhm, is, that O. was a chief of the Oëir, a Scythian tribe, who, fleeing before the ruthless aggressions of the Romans, passed through Germany to Scandinavia, where, by their noble appearance, superior prowess, and higher intelligence, they easily vanquished the inferior races of those lands, and persuaded them that they were of godlike origin. According to one tradition, O. conquered the country of the Saxons on his way; and leaving one of his sons to rule there, and introduce a new religion, in which he, as the chief god Wuotan, received divine honours, advanced on his victorious course, and making himself master of Denmark, placed another son, Skjold, to reign over the land, from whom descended the royal dynasty of the Skjoldingar. He next entered Sweden, where the king, Gylfi, accepted his new religion, and with the whole nation worshipped him as a divinity, and received his son Yugni as their supreme lord and high-priest, from whom descended the royal race of the Yuglingars, who long reigned in Sweden. In like manner he founded, through his son Scoring, a new dynasty in Norway; and besides these, many sovereign families of Northern Germany, including our own Saxon princes, traced their descent to Odin. As it has been found impossible to refer to one individual all the mythical and historical elements which group themselves around the name of O., Wodin, or Wuotan, it has been suggested by Suhm and other historians, that there may have been two or three ancient northern heroes of the name; but notwithstanding the conjectures which have been advanced since the very dawn of the historical period in the north in regard to the origin and native country of the assumed O., or even the time at which he lived, all that relates to him is shrouded in complete obscurity. It is much more probable, however, that the myth of O. originated in nature-worship. See SCANDINAVIAN MYTHOLOGY.

ODOACER (also ODOVACER, ODOBAGAR, ODOVACHAR, OTACHAR, &c., and, according to St Martin, the same as OTTOCHAR, a name frequent in Germany during the middle ages), the ruler of Italy from the year 476 to 493, was the son of Edecon, a secretary of Attila, and one of his ambassadors to the court of Constantinople. This Edecon was also captain of the Scyrr, who formed the bodyguard of the king of the Huns. After the death of Attila, he remained faithful to the family of his master, but perished about 463 in an unequal struggle with the Ostrogoths. He left two sons, Onulf and Odoacer, the former of whom went to seek his fortune in the East; while O., after leading for some time the life of a bandit chief among the Noric Alps, determined to proceed to Italy, whither barbarian adventurers were flocking from all Europe. According to a monkish legend, a pious hermit, St Severinus, whom he went to visit before his departure, prophesied his future greatness. O. entered the military service of the Western Roman Empire, and rapidly rose to eminence. He took part in the revolution by which Orestes (476) drove the Emperor Julius Nepos from the throne, and conferred on his son Romulus the title of Augustus, which the people scoffingly changed into Augustulus. He soon perceived the weakness of the new ruler, and resolved to profit by it. He had little difficulty in persuading the barbarian soldiery, who had effected the revolution, that Italy belonged to them, and in their name demanded of Orestes the third part of the land, as the reward of their help. This Orestes refused; and O., at the head of his Herulians, Rugians, Turcilingians, and Scyrr, marched against Pavia, which Orestes had garrisoned, stormed the city, and put his opponent to death (476). Romulus abdicated, and withdrew into obscurity. What

became of him, is not known. Thus perished the Roman empire. O. shewed himself to be a wise, moderate, and politic ruler, quite unlike our general notion of a barbarian. In order not to offend the Byzantine emperor Zeno, he took the title of king only, and caused the senate to despatch to Constantinople a flattering letter, in which it declared one emperor to be enough for both East and West; renounced its right of appointing the emperors, expressed its confidence in the civil and military talents of O., and begged Zeno to confer upon him the administration of Italy. After some hesitation, the Byzantine emperor yielded to the entreaties of the senate, and O. received the title of *Patricius*. He fixed his residence at Ravenna. According to his promise, he divided among his companions the third part of the land of Italy—a measure far less unjust than at first sight may seem, for the peninsula was then almost depopulated, and many domains were lying waste and ownerless. This barbarian ruler did everything in his power to lift Italy out of the deplorable condition into which she had sunk, and to breathe fresh life into her municipal institutions—those venerable relics of nobler days! He even re-established the consulate, which was held by eleven of the most illustrious senators in succession, maintained peace throughout the peninsula, overawed the Gauls and Germans, and reconquered Dalmatia and Noricum. In religion, though an Arian himself, he acted with a kingly impartiality that more orthodox monarchs have rarely exhibited. Gibbon remarks, with his usual pointed sarcasm, that the *silence* of the Catholics attests the toleration which they enjoyed. The valour, wisdom, and success of O. appear to have excited the jealousy and alarm of Zeno, who encouraged Theodoric, king of the Ostrogoths, a still greater warrior and sovereign than O. himself, to undertake an expedition against Italy. The first battle was fought on the banks of the Isontius (mod. *Isonzo*), 28th August 489. O. was beaten, and retreated. During his retreat, he hazarded another battle at Verona, and was again beaten. He now hastened to Rome, to rouse the inhabitants, but the gates of the city were closed against him. Returning northwards to his capital, Ravenna, he reassembled the wrecks of his army, and in 490 once more marched against the Ostrogoths, whose advance-guard he defeated, and pursued to the walls of Pavia. Another great battle now took place on the banks of the Adda, when O. was vanquished for the third time. He now shut himself up in Ravenna, where Theodoric besieged him for three years. O. then capitulated, on condition that the kingdom of Italy should be shared between him and Theodoric. This agreement was solemnly sworn to by both parties, 27th February 493; but on the 5th of March, O. was assassinated at a feast, either by Theodoric himself, or by his command.

ODOMETER (Gr. *odos*, a road, *métrōn*, a measure), also called *Perambulator*, or *surveying-wheel*, is an instrument attached to a carriage or other vehicle, for the purpose of registering the distance it has travelled. Such machines have been in use from an early period, and one is described by Vitruvius in that part of his work *De Architectura* which is devoted to machines. The instrument, as commonly employed, consists of a train of wheel-work, which communicates motion from the axle of the carriage wheel to an index which moves round the circumference of a dial fixed in one side of the carriage over the axle. The wheel-work is arranged so as to produce a great diminution of the velocity impressed by the axle of the vehicle, and the dial is so graduated that the index can shew the number of miles, furlongs, yards, &c., traversed. The instrument

is also constructed to work independently, being in this case provided with wheels and an axle of its own; when this is done, the wheel is made of such a size that its circumference is an aliquot part of a mile, an arrangement which greatly simplifies the calculation of the distance traversed. The complete odometer can then be drawn along by a man on foot, or attached behind a carriage. See PEDOMETER.

O'DONNELL, LEOPOLD, Duke of Tetuan, Marshal of Spain, born in 1809, was descended from an ancient Irish family. He entered the Spanish army when young, and bravely espoused the cause of the infant Queen Isabella against her uncle, Don Carlos. When the Carlists were overthrown, he was created Count of Lucena, made General of Brigade, and Chief of the Staff to Espartero. He took the side of the Queen-mother in 1840; emigrated with her to France, at the time when her cause seemed desperate; and took up his residence at Orleans, where he planned many of the political risings and disturbances which took place under the rule of Espartero. He headed in person a revolt of the Navarrese against the minister, but on its failure returned to France. In 1843, his intrigues against Espartero (q. v.) were successful; and he was rewarded by the governor-generalship of Cuba, where he amassed a large fortune by favouring the iniquitous trade in slaves. When he returned to Spain (1845) he intrigued against Bravo Murillo and Narvaez; and when the latter was succeeded by Sartorius, O'D., proscribed by the government, headed a military insurrection. Defeated, and driven into Andalusia in 1854, he issued a liberal manifesto. When Espartero gave in his adhesion, the Spaniards rose *en masse*, and replaced the ex-regent at the helm. Espartero made O'D. a marshal and minister of war. O'D. again plotted against his old benefactor, and in 1856 supplanted him by a *coup d'état*. He was in three months' time succeeded by Narvaez, but in 1858 he returned to power; and in 1859 he commanded the army in Morocco. The campaign was tedious; but at last O'D., gaining a complete victory, took the Moorish camp, and the city of Tetuan surrendered. The Emperor of Morocco submitted to a loss of territory, and O'D. was made Duke of Tetuan. In 1866 his cabinet was upset by Narvaez. He then retired to Paris, and died at Biarritz in 1867. The O'D. ministry improved the finances, army, and administration of Spain.

ODONTORNITHES is the name proposed by Marsh for the toothed birds of which some have been described for the first time by him. Marsh divides the O. into three orders, making the European *Archaeopteryx* (see SOLENOHOFEN LITHOGRAPHIC STONE) the first. The remains of the second and third orders have recently been found in considerable quantities in the middle cretaceous formations of Kansas. The *Hesperornis* was a large-boned aquatic animal without power of flight, but probably with strong powers of swimming and diving. From bill to tail, its length was six feet; the neck was long and flexible; the teeth, covered with smooth enamel, terminated upwards in conical pointed crowns, and downwards in stout fangs. The third order, *Ichthyornis*, is subdivided into two genera, *Ichthyornis* and *Apatornis*, both smaller birds resembling terns. See Marsh's monograph, *Odontornithes* (1880).

CECOLAMPADIUS, JOANNES—a name Latinised from the German JOHANN HAUSCHEIN—one of the most eminent of the coadjutors of Zwingli in the Swiss Reformation, born in 1482 at Weinsberg, in Swabia. He relinquished the study of law at Bologna for that of theology at Heidelberg, became tutor to the sons of the Elector Palatine, and subse-

quently preacher in Weinsberg. This office he resigned in order to study the Greek language under Reuchlin at Stuttgart. He also learned Hebrew from a Spanish physician, Matthew Adrian. Being appointed preacher at Basel, he formed the acquaintance of Erasmus, who highly appreciated his classical attainments, and employed his assistance in his edition of the New Testament. In 1516, C. left Basel for Augsburg, where also he filled the office of preacher, and where he entered into a convent. But Luther's publications exercised so great an influence on him, that he left the convent, and became chaplain to Franz von Sickingen, after whose death he returned to Basel in 1522, and in the capacity of preacher and professor of theology, commenced his career as a reformer. He held disputations with supporters of the Church of Rome in Baden in 1526, and in Bern in 1528. In the controversy concerning the Lord's Supper, he gradually adopted more and more the views of Zwingli, and at last maintained them in 1525, in a treatise, to which the Swabian ministers replied in the *Syngramma Suevicum*. In 1529 he disputed with Luther in the conference at Marburg. He died at Basel, 23d November 1531, not long after the death of his friend Zwingli. He was remarkable for his gentleness of character. His treatise, *De Ritu Paschali*, and his *Epistola Canoniorum Indocorum ad Ecclesiam*, are the most noted of his works.—See Herzog, *Das Leben des Joh. Ecolampadius* (1843); and Hagenbach's *Ecolampadius* (1859).

CECUMENICAL (Gr. *oikoumenike*, 'of, or belonging to, the *oikoumene*, 'the world'), the name given to councils of the entire church, and synonymous with the more ordinary name 'general.' See COUNCIL. The conditions necessary to constitute an œcumenical council are a subject of much controversy. As the subject is of less importance in Protestant divinity, it will be enough to explain here that a council is said by Roman Catholic divines to be œcumenical in three different ways: viz., in convocation, in celebration, and in acceptance. For the first, the summons of the pope, direct or indirect, is held to be necessary; this summons must be addressed to all the bishops of the entire church. To the second, it is necessary that bishops from all parts of the church should be present, and in sufficient numbers to constitute a really representative assembly: they must be presided over by the pope, or a delegate or delegates of the pope; and they must enjoy liberty of discussion and of speech. For the third, the decrees of the council must be accepted by the pope, and by the body of the bishops throughout the church, at least tacitly. The last of these conditions is absolutely required to entitle the decrees of a council to the character of œcumenical; and even the decrees of provincial or national councils so accepted, may acquire all the weight of infallible decisions, in the eyes of Roman Catholics.

CEDEMA (Gr. *a swelling*) is the term applied in Medicine to the swelling occasioned by the effusion or infiltration of serum into cellular or areolar structures. The subcutaneous cellular tissue is the most common, but is not the only seat of this affection. It is occasionally observed in the submucous and subserous cellular tissue, and in the cellular tissue of the parenchymatous viscera; and in some of these cases, it gives rise to symptoms which admit of easy recognition during life. Thus œdema of the glottis (see LARYNX) and œdema of the lungs constitute well-marked and serious forms of disease; while œdema of the brain, though not easily recognised during life, is not uncommonly met with in the *post-mortem* examination of insane patients.

Œdema may be either passive or active, the former being by far the most common. *Passive Œdema* arises from impeded venous circulation (as from obstruction or obliteration of one or more veins; from varicose veins; from standing continuously for long periods, till the force of the circulation is partly overcome by the physical action of gravitation; from deficiency in the action of the adjacent muscles, which in health materially aids the venous circulation, &c.); from too weak action of the heart (as in dilatation or certain forms of valvular disease of that organ); or from a too watery or otherwise diseased state of the blood (as in chlorosis, scurvy, Bright's disease, &c.). By means of the knowledge derived from pathological anatomy, we can often infer the cause from the seat of the swelling; for example, œdema of the face, usually commencing with the eyelids, is commonly caused by obstruction to the circulation through the left side of the heart, or by the diseased state of the blood in Bright's disease; and œdema of the lower extremities most commonly arises from obstruction in the right side of the heart, unless it can be traced to the pressure of the gravid uterus, or of accumulated fæces in the colon, or to some other local cause.

Active Œdema is associated with an inflammatory action of the cellular tissue, and is most marked in certain forms of erysipelas. It is firmer to the touch, and pressure with the finger produces less pitting than in the passive form.

From the preceding remarks, it will be seen that œdema is not a disease, but a symptom, and often a symptom indicating great danger to life. The means of removing it must be directed to the morbid condition or cause of which it is the symptom.

ŒDIPUS (Gr. *Oidipous*), the hero of a celebrated legend, which, though of the most revolting nature in itself, has supplied both Euripides and Sophocles with the subject-matter of some of their most celebrated tragedies. The story, as generally related, is as follows: ŒE was the son of Laius, king of Thebes, by Jocaste; but his father having consulted the oracle to ascertain whether he should have any issue, was informed that his wife would bring forth a son, by whom he (Laius) should ultimately be slain. Determined to avert so terrible an omen, Laius ordered the son which Jocaste bore him to have his feet pierced through, and to be exposed to perish on Mount Cithæron. In this helpless condition, ŒE was discovered by a herdsman, and conveyed to the court of Polybus, king of Corinth, who, in allusion to the swollen feet of the child, named him *Œdipus* (from *oideo*, to swell, and *pous*, the foot); and along with his wife, Merope, brought him up as his own son. Having come to man's estate, ŒE was one day taunted with the obscurity of his origin, and in consequence proceeded to Delphi, to consult the oracle. The response which he received was, that he would slay his father, and commit incest with his mother. To escape this fate, he avoided returning to Corinth, and proceeded to Thebes, on approaching which he encountered the chariot of his father; and the charioteer ordering him out of the way, a quarrel ensued, in which ŒE ignorantly slew Laius, and thus unconsciously fulfilled the first part of the oracle. The famous Sphinx (q. v.) now appeared near Thebes, and seating herself on a rock, propounded a riddle to every one who passed by, putting to death all who failed to solve it. The terror of the Thebans was extreme, and in despair they offered the kingdom, together with the hand of the queen, to the person who should be successful in delivering it from the monster. ŒE came

forward; the Sphinx asked him, 'What being has four feet, two feet, and three feet; only one voice; but whose feet vary, and when it has most, is weakest?' ŒE replied that it was 'Man;' whereupon the Sphinx threw itself headlong from the rock. ŒE now became king, and husband of his mother, Jocaste. From their incestuous union sprung Eteocles, Polynices, Antigone, and Ismene. A mysterious plague now devastated the country, and when the oracle declared that before it could be stayed, the murderer of Laius should be banished from the country, ŒE was told by the prophet Tiresias that he himself had both murdered his father and committed incest with his mother. In his horror he put out his own eyes, that he might no more look upon his fellow-creatures, while Jocaste hanged herself. Driven from his throne by his sons and his brother-in-law, Creon, ŒE wandered towards Attica, accompanied by Antigone, and took refuge in the grove of the Eumenides, who charitably removed him from earth; but the latter part of his life is differently told.

ŒHELENSCHLÄGER, ADAM GOTTLÖB, the greatest poet of Northern Europe, was born in 1779 at Copenhagen. His early years were spent at the palace of Fredericksborg, in the neighbourhood of the Danish capital, where his father was employed, first as organist, and afterwards as steward or bailiff. During the absence of the royal family in the winter, ŒE and his sister amused themselves in roaming over the palace, and examining the paintings and works of art which it contained, and in improvising private theatricals, for which he supplied original pieces. After an irregular and desultory course of education, ŒE's love of the drama led him to offer his services to the manager of the Copenhagen theatre; but discovering soon that he had no chance of rising above the rank of a mere supernumerary, he entered the university of Copenhagen as a student of law. For a time, he seems to have pursued his studies with tolerable assiduity, under the direction of his friend, A. S. Oersted, who, together with his distinguished brother, H. C. Oersted (q. v.) had cemented a lifelong friendship with him. ŒE's studies were interrupted in 1801, when, on the bombardment of Copenhagen by Nelson and Parker, he and his friends served in the student-corps of volunteers. After this event, which roused the dormant patriotism of the nation, ŒE found the study of law too irksome, and devoted all his energies to the cultivation of the history and mythology of his own country. In 1803, appeared his first collection of poems, including one longer dramatic piece, *St Hans Aften-Spil*, which attracted favourable notice for the lively fancy with which national habits and local characteristics were portrayed. The *Vaulunders Saga* in the *Poetiske Skrifter*, published in 1806, and his *Aladdin's forunderlige Lampe*, completed his success, and raised him to the rank of the first of living Danish poets; the former of these works having shewn a marvellous capacity for reflecting the dark and stern colouring of the old northern Sagas, while the latter gave evidence of a rich and genial poetic fancy. These early efforts were rewarded by the acquisition of a travelling pension, which enabled him to spend some years in visiting various parts of the continent, and becoming acquainted with the great literary celebrities of the day, such as the Weimar circle of whom Goethe was the head. During this period, ŒE wrote his *Hakon Jarl*, the first of his long series of northern tragedies, at Halle (1807; Eng. trans. by F. C. Lascelles, 1875), and his *Correggio*, at Rome (1809; Eng. trans. by Theodore Martin, 1854). In 1810, ŒE returned to Denmark, where he was hailed with acclamation

as the greatest tragic poet Denmark had ever known; and having soon afterwards obtained the chair of aesthetics at the university, and received various substantial proofs of royal favour, he married, and settled in the capital, where his peace was, however, rudely disturbed by a literary feud with Baggesen, the Danish poet and critic, whose poetical supremacy had been superseded by that of Ehlerschläger. In 1819 appeared one of CE's most masterly productions, *Nordens Guder*, and this and the numerous dramatic compositions written about the same period, shew that the severe criticism to which his writings had been exposed during the celebrated Baggesen quarrel, had corrected some of the faults, and lessened the self-conceit which had characterised his earlier works. His reputation spread with his increasing years both abroad and at home; and after having repeatedly visited the more southern parts of Europe, he went in 1829 to Sweden, where his arrival was welcomed by a public ovation; and after having received repeated marks of friendship from various sovereigns, he was honoured in his own country by the celebration, in 1849, of a grand public festival held in the palace at Copenhagen. But this ovation was unfortunately followed in less than two months by his death, which took place in January 1850. His funeral was kept as a national solemnity, and he was followed to the grave by a civic procession, which included members of every class of society, from princes to artisans. The fame of CE will rest principally on his tragedies, of which he wrote 24, 19 of the number being on northern subjects. These were all composed originally in Danish, and re-written by himself in German. Besides those already referred to, the best are *Knud den Store*, *Palnatoke*, *Azel og Walborg*, *Væringerne i Miklagord*. His poems are for the most part indifferent, and his numerous prose writings deserve little notice. His Danish and German works amount in all to 62 volumes, to which must be added 4 volumes of his *Erindringer*, or *Autobiographical Recollections*, published after his death.

CEIL DE BŒUF, a French term literally signifying ox's eye, applied in architecture to those small round or oval openings in the frieze or roof of large buildings, which serve to give light to spaces otherwise dark. The most famous is that in the anteroom (where the courtiers waited) of the royal chamber at Versailles, which gave name to the apartment. Hence the expression, *Les Fastes de l'Œil-de-Bœuf*—i.e., the history of the courtiers of the Grand Monarque, and by extension, of courtiers in general.

CE'LAND, a long and narrow island in the Baltic, lying off the eastern coast of Sweden, opposite to, and forming part of, the län of Kalmar, and at a distance of from 4 to 17 miles from the shore. It is 85 miles in length, and from 2 to 8 miles in breadth. The area is 538 square miles, and the pop. 45,000. The island, which is scarcely more than a lime cliff, is scantily covered with soil, but in some parts it is well wooded, and has good pasture-ground, which is turned to account by the islanders, who rear cattle, horses, and sheep. In favourable seasons, barley, oats, and flax yield good crops. The fishing is excellent all round the coasts. There are large alum-works on the island, and an extensive line of wind-mills along the range of the Alwar Hills, near which stands Borgholm (pop. 900), the only town on the island, the first foundations of which were laid in 1817. To the north of the island lies the steep but wooded island-cliff, the Jungfruen, or Blaskulla, which bears the mythical reputation of having been the scene of

various deeds of witchcraft, and the favourite resort of wizards and witches.

OELS, a small town of Prussian Silesia, stands on a plain on the Oelsa, or Oelse, 16 miles east-north-east of Breslau. Its castle, built in 1558, is surrounded by ramparts and ditches. It contains a gymnasium, several churches, and other public edifices. Pop. (1880) 10,157, who carry on manufactures of shoes and of cloth goods.

ŒNANTHYLIC ACID ($C_{21}H_{33}O_2$, HO) is one of the volatile fatty acids of the general formula $C_nH_{2n}O_2$. It is a colourless oily fluid, with an aromatic odour, lighter than water, and insoluble in that fluid, but dissolving readily in alcohol and ether. According to Miller (*Organic Chemistry*, 2d ed. p. 355), it may be exposed to a cold of 0° without becoming solid; while it boils and may be distilled (with partial decomposition) at 298° . It is (like many of the allied fatty acids) one of the products of the oxidation of Oleic Acid (q.v.) by nitric acid, and is likewise yielded by the action of nitric acid on castor oil, wax, and various fats. Its most characteristic salt is the œnanthylate of copper, which crystallises in beautiful green needles.

ŒNOTHERA, a genus of plants of the natural order *Onagraceæ* (q.v.), having four petals and eight stamens, the calyx-lobes 4-cleft, the segments reflexed; the capsule 4-valved, with many naked seeds. The EVENING PRIMROSE (*Œ. biennis*), a native of Virginia, has been known in Europe since 1614, and is now naturalised in many parts of Europe

Evening Primrose (*Œnothra biennis*):
a, flower divested of calyx and corolla, to shew the parts of fructification; b, tuberous root.

and in some parts of Britain, on the banks of rivers, in thickets, on sandy grounds, &c. It is a biennial plant, and produces in the first year elliptic or obovate obtuse leaves, and in the second year a stem of 1½—4 feet high, which bears at its summit numerous yellow flowers in a leafy spike. The flowers are fragrant in the evening. The root somewhat resembles a carrot in shape, but is short; it is usually red, fleshy, and tender; it is eaten in salads or in soups, and as a boiled vegetable. The plant is often cultivated for the sake of its large yellow flowers. Several other species of *Œnothra*, natives of North America, are occasionally cultivated in our gardens, and have eatable and pleasant roots.

OERE'BRO, an inland town of Sweden, capital of a län of the same name, is situated at the entrance of the Swart-Elf into the Heilmar Lake,

100 miles west of Stockholm. Pop. (1880) 11,785. The town still retains many memorials of its earlier prosperity, when it was frequently the residence of the Swedish rulers, who found its central position in the more fertile southern portion of the kingdom favourable both in regard to safety and pleasantness of site. The old castle was built by Berger Jarl in the 13th c., and was in after-times frequently chosen as the seat of the national diets. O. has manufactories of wax-cloth, carpets, woollen goods, stockings, guns, and mirrors; and these industrial products, together with the minerals obtained from the neighbouring silver, copper, and iron mines, are conveyed to Gothenborg and Stockholm by means of the extensive system of canals which connects the lakes of the interior with the maritime ports.

OERSTED, HANS CHRISTIAN, one of the most distinguished scientific discoverers and physicists of modern times, was born in 1777 at Rudkjøbing, on the Danish island of Langeland, where his father practised as an apothecary. In 1794, he entered the university of Copenhagen, where he took the degree of doctor of philosophy in 1799, and soon afterwards became assistant to the professor of medicine, in which capacity he gave lectures on chemistry and natural philosophy. In 1806, after having enjoyed a travelling scholarship for several years, and visited Holland, the greater part of Germany, and Paris, he was appointed extraordinary professor of natural philosophy in the university of Copenhagen. In 1812, he again visited Germany and France, after having published a manual under the title of *Videnskaben om Naturen's Almindelige Love*, and *Første Indledning til den Almindelige Naturlære* (1811). During his residence at Berlin, he wrote his famous essay on the identity of chemical and electrical forces, in which he first developed the ideas on which were based his great discovery of the intimate connection existing between magnetism and electricity and galvanism—a treatise which, during his residence in Paris, he translated into French, in conjunction with Marcel de Serres. In 1819, he made known these important truths in a Latin essay, entitled *Experimenta circa Efficaciam Conflictus Electrici in acum Magneticam*, which he addressed to all the scientific societies and the leading savans of Europe and America, and thus made good his claim to be regarded as the originator of the new science of electro-magnetism. This discovery, which formed one of the most important eras in the history of modern physical science, obtained for O. the Copley Medal from the Royal Society of England, and the principal mathematical prize in the gift of the Institute of Paris. The original and leading idea of this great discovery had been in his mind since 1800, when the discovery of the galvanic battery by Volta had first led him to enter upon a course of experiments on the production of galvanic electricity. The enunciation of his theory of electro-magnetism was followed by many important experiments in regard to the compression of water, and by numerous other chemical discoveries, among which we may instance his demonstration of the existence of the metal aluminium in alumina. The influence which O. exerted on the science of the day by his discoveries, was recognised by the learned in every country, and honours increased upon him with increasing years. He was corresponding member of the French Institute, perpetual secretary to the Royal Society of Sciences in Copenhagen, a knight of the Prussian Order of Merit, of the French Legion of Honour, and of the Danish Order of the Dannebrog, and a councillor of state. O.'s great object through life was to make science popular among all classes, in furtherance of which he wrote numerous

works, contributed scientific papers to the newspapers and magazines of his own country and Germany, and in addition to his regular prelections in the university, gave courses of popular scientific lectures to the public including ladies. Among the works specially written to promote the diffusion of scientific knowledge, those best known are *Aanden's Naturen* (Kop. 1845), and *Natur-lærens Mechaniske Deel* (Kop. 1847), both of which have been translated into several other European languages. The majority of his more important physical and chemical papers are contained in Poggendorff's *Annalen*, and were written by him in German or French, both of which he wrote with the same facility as his own language. At the close of 1850, a national jubilee was held in honour of the 50th anniversary of his connection with the university of Copenhagen—a festival which he did not long survive, as his death occurred at Copenhagen 9th March 1851. A public funeral, attended by all persons distinguished by rank or learning in the Danish capital, bore testimony to the respect and esteem with which he was regarded by his fellow-citizens, among whom his memory is cherished, not merely as one of the greatest scientific benefactors of his times, but as a man who contributed largely, by his eloquent and earnest advocacy of liberal principles, to the attainment of the high degree of constitutional freedom which Denmark now enjoys.

ŒSOPHAGUS (Gr. *oio*, to convey, and *phagein*, to eat), or GULLET, a membranous canal, about nine inches in length, extending from the pharynx to the stomach, and thus forming a part of the alimentary canal. It commences at the lower border of the cricoid cartilage of the larynx, descends in a nearly vertical direction along the front of the spine, passes through an opening in the diaphragm, and thus enters the abdomen, and terminates in the cardiac orifice of the stomach opposite the ninth dorsal vertebra. It has three coats—viz, an external or muscular coat (consisting of two strata of fibres of considerable thickness—an external, longitudinal, and an internal, circular); an internal or mucous coat, which is covered with a thick layer of squamous epithelium; and an intermediate cellular coat, uniting the muscular and mucous coats. In this tissue are a large number of oesophageal glands, which open upon the surface by a long excretory duct, and are most numerous round the cardiac orifice, where they form a complete ring.

The œsophagus is liable to a considerable number of morbid changes, none of which are, however, of very common occurrence.

The most prominent symptom of *Œsophagitis*, or *Inflammation of the Œsophagus*, is pain between the shoulders, or behind the trachea or sternum, augmented in deglutition, which is usually more or less difficult, and sometimes impossible. The affection is regarded as a very rare one, unless when it originates from the direct application of irritating or very hot substances, or from mechanical violence—as, for instance, from the unskillful application of the stomach-pump or probang. Dr Copland, however, is of opinion that it is not unfrequent in children, particularly during infancy, and observes that 'when the milk is thrown up unchanged, we should always suspect the existence of inflammation of the œsophagus.' The ordinary treatment employed in inflammatory diseases must be adopted; and if inability to swallow exists, nourishing liquids, such as strong beef-tea, must be injected into the lower bowel.

Spasm of the Œsophagus—a morbid muscular contraction of the tube, producing more or less difficulty of swallowing—is a much more common affection than inflammation. The spasm generally comes on

suddenly during a meal. Upon an attempt to swallow, the food is arrested, and is either immediately rejected with considerable force, or is retained for a time, and then brought up by regurgitation; the former happening when the contraction takes place in the upper part of the canal, and the latter when it is near the lower part. In some cases, solids can be swallowed, while liquids excite spasm; while in other cases the opposite is observed; but in general either solids or liquids suffice to excite the contraction, when a predisposition to it exists. The predisposition usually consists in an excitable state of the nervous system, such as exists in hysteria, hypochondriasis, and generally in a debilitated condition of the body. An attack may consist of a single paroxysm, lasting only a few hours, or it may be more or less persistent for months or even years. The treatment must be directed to the establishment of the general health, by the administration of tonics and anti-spasmodics, by attention to the bowels and the various secretions, by exercise in the open air, the shower-bath, a nutritious diet, &c.; and by the avoidance of the excessive use of strong tea, coffee, and tobacco. Care must also be taken not to swallow anything imperfectly masticated or too hot; and the occasional passage of a bougie is recommended. Brodie relates a case that ceased spontaneously on the removal of bleeding piles. Strychnia is deserving of a trial when other means fail; and if the affection assume a decidedly periodic form, quinia will usually prove an effectual remedy.

Paralysis of the Œsophagus is present in certain forms of organic disease of the brain or spinal cord, which are seldom amenable to treatment, and is often a very important part of the palsy that so frequently occurs in the most severe and chronic cases of insanity. In this affection there is inability to swallow, but no pain or other symptom of spasm; and a bougie may be passed without obstruction. The patient must be fed by the stomach-pump, and nutrient injections of strong beef-tea should be thrown into the lower bowel.

Permanent or Organic Stricture of the Œsophagus may arise from inflammatory thickening and induration of its coats, or from scirrhus and other formations, situated either in the walls of or external to the tube. The most common seat of this affection is at its upper part. The symptoms are persistent and gradually increasing difficulty of swallowing, occasionally aggravated by fits of spasm; and a bougie, when passed, always meets with resistance at the same spot. When the contraction is due to inflammatory thickening, it may arise from the abuse of alcoholic drinks, or from swallowing boiling or corrosive fluids; and it is said that it has been induced by violent retching in sea-sickness. If unrelieved, the disease must prove fatal, either by ulceration of the tube around the seat of the stricture, or by sheer starvation. When the affection originates in inflammation, some advantage may be derived from a mild course of mercury, occasional leeching, and narcotics; and especially from the occasional passage of a bougie, of a ball-probang (an ivory ball attached to a piece of whalebone), or of a piece of sponge moistened with a weak solution of nitrate of silver. If it is dependent upon malignant disease, and the tissues have become softened by the infiltration of the morbid deposit, the bougie must be directed with the greatest care through the stricture, as a false passage may be easily made into important adjacent cavities.

Foreign bodies not very unfrequently pass into the œsophagus, and become impacted there, giving rise to a sense of choking and fits of suffocative cough, especially when they are seated in its

upper part. They may not only cause immediate death by exciting spasm of the glottis, but if allowed to remain, may excite ulceration of the parts, and thus cause death by exhaustion. If the body is small and sharp (a fish-bone, for example), it may often be got rid of by making the patient swallow a large mouthful of bread; if it is large and soft (such as too large a mouthful of meat), it may generally be pushed down into the stomach with the probang; while large hard bodies (such as pieces of bone) should be brought up either by the action of an emetic, or by long curved forceps. If the offending body can neither be brought up nor pushed down, it must be extracted by the operation of *Œsophagotomy*—an operation which can only be performed when the impacted body is not very low down, and which it is unnecessary to describe in these pages.

CESTRIDÆ, a family of dipterous insects, having a mere rudimentary proboscis or none, the palpi also sometimes wanting, and the mouth reduced to three tubercles; the antennæ short and enclosed in a cavity in the forepart of the head; the abdomen large. They are generally very hairy, the hair often coloured in rings. They resemble flesh-flies in their general appearance, and are nearly allied to *Muscidæ*. The perfect insect is very short-lived. The females deposit their eggs on different species of herbivorous mammalia, each insect being limited to a particular kind of quadruped, and selecting for its eggs a situation on the animal suitable to the habits of the larvæ, which are different in different species, although the larvæ of all the species are parasites of herbivorous quadrupeds. The characters and habits of some of the most notable species are described in the article *BOT*. Animals seem generally to have a strong instinctive dread of the *O.* which infest them.

OFFENBACH, JAQUEB. See SUPP., Vol. X.

OFFENBACH, a manufacturing town of Hesse-Darmstadt, on the south bank of the river Main, within the domains of the Princes of Isenburg-Birstein, 4 miles south-east of Frankfurt. Pop. (1880) 28,449. *O.* is pleasantly situated in one of the richest parts of the valley of the Main, and is one of the most important manufacturing towns in the province. Among the industrial products, its carriages have acquired a pre-eminent character for excellence; and next to these, stand its book-bindings, articles of jewellery, gold and silver goods, carpets, and silk fabrics. It has also good manufactories of wax-cloth, papier-mâché snuff-boxes, tin-lacquered wares, umbrellas and parasols, wax-candles, leather, hats, tobacco, sugar, and ginger-bread and spiced cakes. *O.* has several churches, and a Jewish synagogue. The palace is the winter residence of the Isenburg-Birstein family, to whom the old castle, now in ruins, also belongs. A pontoon-bridge across the river, and a railway to Frankfurt, facilitate intercommunication, and tend materially towards the maintenance of its active trade.

OFFENCES AGAINST RELIGION, PUBLIC PEACE, &c. See RELIGION, PEACE, &c.

OFFER AND ACCEPTANCE is one mode of entering into a contract of sale. At an auction, the highest offer is generally accepted as a matter of course; and when accepted, the contract is completed. An offer is often made by letter from one merchant to another to buy or sell goods. In such a case, the party offering is bound to wait until he gets an answer by return of post or messenger; for until then the offer is supposed to be continuously made. But if A offer to B personally to sell, and B ask time to consider for a day, or any given time, A is not bound to wait a single moment, according to

English law, and may withdraw at any time from the offer, because he had no legal consideration for waiting; whereas, in Scotland, in the same circumstances, A would be bound to wait the time agreed upon.

OFFERING. Under the head **FIRST-FRUIT** (q. v.) have been described the various offerings prescribed in the Jewish law. We shall have occasion to consider, under the head of **SACRIFICE** (q. v.), some further questions connected with the subject of offerings in public worship. In the Christian community there appears to have existed, from the earliest times, a practice of making voluntary offerings, for purposes not directly connected with public worship. See **OFFERTORY**.

OFFERTORY (Lat. *offertorium*, from *offero*, I offer) is the name given to that portion of the public liturgy of the Roman Catholic Church with which the eucharistic service, strictly so called, commences. In the Roman Liturgy it consists of one or two verses from some book of Scripture, generally from the Old Testament, but sometimes also from the Epistles. In the Ambrosian Liturgy it consists of a prayer, similar in form to the *collect* or *secret* of the mass; and in both, this recital is followed by the preparatory offering up of the bread and wine, accompanied by certain ceremonies and forms of prayer.

This offering of the bread and wine in the public service became, from a very early period, the occasion of a voluntary offering, on the part of the faithful; originally, it would seem, of the bread and wine designed for the eucharistic celebration and for the communion of the priest and the congregation, sometimes even including the absent members, and also for the *agape*, or common sacred feast, which accompanied it. That portion of the offerings which remained in excess of what was requisite for these purposes was applied to the relief of the poor, and to the support of the clergy. These offerings were ordinarily made by the faithful in person, and were laid upon the altar; and the Ambrosian rite still preserves this usage in a ceremonial which may be witnessed in the cathedral of Milan. By degrees, other gifts were superadded to those of bread and wine—as of corn, oil, wax, honey, eggs, butter, fruits, lambs, fowl, and other animals; and eventually of equivalents in money or other objects of value. The last-named class of offerings, however, was not so commonly made upon the altar and during the public liturgy, as in the form of free gifts presented on the occasion of other ministerial services, as of baptism, marriages, funerals, &c.; and from this has arisen the practice in the Roman Catholic Church of the mass-offering, or *honorarium*, which is given to a priest with the understanding that he shall offer the mass for the intention (whence the honorarium itself is often called an 'intention') of the offerent. In some places, however, and among them in some parts of Ireland, offerings 'in kind' are still in use, not indeed in the form of the ancient offertory, but in the shape of contributions of corn, hay, &c., at stated seasons, for the use of the parochial clergy. At weddings also, and in some places at funerals, offerings in money are made by the relations and friends of the newly married or of the deceased. In the Liturgy of the English Church allusion is made to the practice of oblations, and some of the recent controversies have turned upon the revival of the 'offertory,' which has found some advocates.

OFFICE, THE DIVINE (Lat. *officium*, duty), is the name popularly given to the **CANONICAL HOURS** (q. v.) prescribed to be read each day by bishops, priests, deacons, and sub-deacons in the Roman

Catholic Church. Under the head **BREVIARY** will be found a general description of the contents and the arrangement of that great service-book. The special portions assigned for any particular day constitute what is called the divine office for that day; and each person who is bound in virtue of his order to recite the Breviary, is obliged, under pain of sin, to read, not merely with the eye, but with distinct, although it may be silent, articulation, each and all these portions. The adjustment of the portions of the office of each day, the combination of the 'ordinary' portions which are read every day in common, with the parts 'proper' for each particular day, is a matter of considerable difficulty, and is regulated by a complicated system of **RUBRICS** (q. v.).

OFFICE, HOLY, CONGREGATION OF THE. In the article **INQUISITION** (q. v.) it has been explained that that tribunal is sometimes called by the name Holy Office. That title, however, properly belongs to the 'Congregation' at Rome, to which the direction of the tribunal of the Inquisition at Rome is subject. This Congregation was established by Paul III. in 1542, and its organisation was completed by Sixtus V. It consists of twelve cardinals, a commissary, consultants, and qualifiers, whose duty it is to examine and report on each case for the information of the cardinals. In the most solemn sessions of the Holy Office the pope himself presides in person. The Holy Office decides questions of heresy, inquires into crimes against faith, and judges ecclesiastical offences, especially in the administration of the sacraments. In the present condition of the papal court, the action of the H. O. is much restricted.

OFFICE COPY is a copy made of a document by some officer of a court in whose custody the document is; and in general such copies are receivable in evidence, without further proof, in the same court, but not in other courts, except some statute makes them evidence.

OFFICERS, MILITARY AND NAVAL.—*Military Officers* are combatant and non-combatant, the latter term including paymasters, medical officers, commissariat, and other civil officers. The great divisions of rank are commissioned, warrant, and non-commissioned officers. Commissioned officers are those holding commissions from the crown, or a lord-lieutenant, and comprise all holding the rank of ensign, or corresponding or superior rank. Divided by duties, they are Staff Officers (see **STAFF**), or Regimental Officers (see **REGIMENT**); divided by rank, General Officers (q. v.), Field-Officers (q. v.), and troop or company officers. The last are captains, lieutenants, and sub-lieutenants, and, except, in the cavalry, are unmounted. The different systems of promotion for officers, and especially the intricacies of the late purchase system, will be explained under **PROMOTION, ARMY, and PURCHASE SYSTEM**. The only warrant officers in the army are Master-gunners (see **GUNNER**) and Schoolmasters. Non-commissioned officers are described under that heading.

Officers, Naval, are commissioned, warrant, and petty officers. Commissioned officers are admirals, captains, commanders, lieutenants, and sub-lieutenants, described under their respective titles. Warrant Officers (q. v.) are boatswains, carpenters, gunners, and one class of engineers. Petty officers will be described under that heading, and constitute a very important portion of the management in a ship-of-war.

OFFICIAL ASSIGNEE, in English Law, is an officer of the Bankruptcy Court, in whom a

bankrupt's estate vests the moment an adjudication of bankruptcy is made. He is the manager of the property, and can sell the estate under the directions of the court in urgent cases, such as where the goods are perishable; but in general, he is assisted in the management by the creditors' assignees, who are selected from the body of creditors by the other creditors' votes. The official assignee is appointed by the Lord Chancellor, being selected from the body of merchants, brokers, or accountants. He is bound to find security to the extent of £6000. He is prohibited from carrying on trade on his own account. The salary is £1000.

OFFICIAL PLANTS (Lat. *officina*, a shop) are those medicinal plants which have a place in the pharmacopoeias of different countries, and which are therefore sold—or some of their products or preparations of them—by apothecaries and druggists. The medicinal plants cultivated to any considerable extent are all official, but many are also official which are not cultivated. See **MEDICINAL PLANTS**.

Offset.

OFFSET, or **SET-OFF**, the splay or sloping part of a wall, &c., joining parallel surfaces when the upper face recedes from the lower. This frequently occurs on buttresses (see fig.). The O. is usually protected with dressed stones, having a projection or drip on the lower edge to prevent the rain from running down the wall.

OFFSETS, a term used by gardeners to designate the young bulbs, which springing from the axils of the scales of a bulb (q. v.), grow beside it, exhausting its strength, but which serve for the propagation of the plant. A crop of shallots, or of potato onions, consists entirely of the offsets of the bulbs planted in spring; although the term is not commonly used except as to bulbous-rooted plants prized for the beauty of their flowers.

OFFSETS. Let AEF....B....D....C be a field with very irregular sides; take the points A, O, M, C at or as near the corners as convenient, the object being to enclose as much of the field as possible within the quadrilateral AOMC; and for this

Fig. 1.

purpose it is sometimes necessary, as in the present case, to include a corner (as SRQ) which is outside the field. The area AOMC is found by means of the diagonal AM, and the perpendiculars on it from C and O. The area AEF....BL is found

by dividing it into triangles and trapezoids by means of perpendiculars (to which the term *offsets* was originally applied, though it now denotes the irregular area before mentioned) from the corners E, G, H, &c. (see **TRIANGLE** and **TRAPEZOID**), and adding together the areas of the separate figures AEF, FGg, GHgh, &c. Similarly the areas of OLN....D and MDUW are found. To the sum of these must be added the areas of the triangles ATS, QPO, diminished by the area of SRQ, and the result is the whole area of the field. If the offset have no distinct corners, as (fig. 2) ABLMN....OK,

Fig. 2.

then the base AK is divided into equal parts by perpendiculars ABL, Mm, Nn, &c., and the area of the offset is found approximately as follows: the whole offset = ABL + LmM + MmNn + &c. + PpOK = $Al \times \frac{1}{2} (AB + Ll) + lm \times \frac{1}{2} (Ll + Mm) + mn \times \frac{1}{2} (Mm + Nn) + \dots + pK \times \frac{1}{2} (pP + OK) =$ (since the divisions of the base are equal) $Al \times \frac{1}{2} \{AB + 2Ll + 2Mm + 2Nn + \dots + 2pP + OK\} = Al \times \left\{ \frac{AB + OK}{2} + Ll + Mm + Nn + \dots + pP \right\};$

i. e., the area of an offset is found approximately by adding the intermediate perpendiculars to the semi-sum of the first and last, and multiplying the sum-total by the length of a division of the base, the divisions being equal; and the greater the number of perpendiculars, the nearer the result is to the true area.

OGDEN, a village in Utah, U.S.; of importance as the place where the Union Pacific and Central Pacific railways join. Pop. (1880) 6069.

O'GDENSBURG, a port in New York, U.S., on the south bank of the St Lawrence, 210 miles N.W. of Albany. It has a large lake and river trade, mills and factories, and a steam-ferry to Prescott in Canada. Pop. (1870) 10,076; (1880) 10,340.

OGEE', a moulding consisting of two curves, one concave and the other

convex (a). It is called (in *Classico Architecture*) *Cymatium* or *Cyma Reversa* (see **MOULDING**). The ogee is also much used in Gothic architecture. An arch having each side formed with two contrasted curves is called an ogee arch (b). Figure a represents Hogarth's line of beauty.

Ogee.

O'GHAMS, the name given to the letters or signs of a secret alphabet long in use among the Irish and some other Celtic nations. Neither the origin nor the meaning of the name has been satisfactorily explained.

The alphabet itself is called *Bethluismín*, or *Bethluís*, from its first two letters, 'b,' called 'beith' (birch), and 'l,' called 'luís' (quicken). Its characters are lines, or groups of lines, deriving their significance from their position on a single stem or chief line—over, under, or through which they are drawn either straight or oblique. In some cases, the edge of the stone or other substance on which the Oghams are incised, serves the purpose of the stem or chief line. About eighty different forms of

the alphabet are known. The following is the one most commonly used :

Ogham Alphabet.

These seem to have been all the letters of the first Ogham alphabet. Five characters were afterwards added to represent diphthongs :

The sign for the diphthong 'ea' is said to be the only one which has been observed on ancient monuments. It is added that the sign for 'ui' sometimes stands for 'y,' that the sign for 'ia' sometimes stands for 'p,' and that the sign for 'ae' stands also for 'z,' for 'cc,' for 'ch,' for 'ach,' and for 'uch.'

Ogham inscriptions generally begin from the bottom, and are read upwards from left to right to the top, when they are carried over, and run down another side or angle. Most of those which have been read give merely a proper name with its patronymic, both in the genitive case. The stones on which Oghams are cut would seem, for the most part, to have been sepulchral. Oghams are of most frequent occurrence in Ireland, where they are found both written on books and inscribed on stones, metals, or bones. The Oghams on stones are most numerous in the counties of Kerry and Cork. A few Ogham inscriptions on stones have been discovered in Wales—as at St Dogmael's, in Pembrokeshire; near Margam, in Glamorganshire; and near Crickehowel, in Brecknockshire. There are a few in Scotland, as on the Newton Stone and the Logie Stone in Aberdeenshire, on the Golspie Stone in Sutherland, and on the Bressay Stone in Shetland. One has been found in England—at Fardel, in Devonshire. Oghams have been observed on an ancient MS. of Priscian, which belonged to the famous Swiss monastery founded in the 7th c. by the Irish missionary, St Gall (q. v.).

The difficulties of deciphering Ogham inscriptions cannot be said to have been as yet altogether overcome. It is confessed by the most learned and judicious of Ogham scholars, the Rev. Charles Graves, D.D., of Trinity College, Dublin, that the nature of the character is such that it does not at once appear which, of four different ways of reading, is the right one; that the words being written continuously, as in ancient MSS., there is great chance of error in dividing them; and that the Celtic names inscribed are generally Latinised in such a manner as not readily to be recognised.

The old school of Irish antiquaries contended that the Oghams were of Persian or Phœnician origin, and were in use in Ireland long before the introduction of Christianity. But this theory is now generally discarded, as not only unsupported, but as contradicted by facts. A comparison of the Ogham alphabet, with the alphabets of Persepolis and Carthage, shews that there is no likeness between them. The great majority of Ogham monuments, it has been observed, bear more or less distinct marks of Christian hands. Several are inscribed with crosses, as old, to all appearance, as the Oghams themselves. Many stand in Christian burying-

grounds, or beside Christian cells or oratories. Some still bear the names of primitive saints. At least one is inscribed with a Christian name; and some of the inscriptions betray an undeniable knowledge of Latin. At the same time, it has been argued by one of the most learned of Celtic philologists, Mr Whitley Stokes, that 'the circumstance that genuine Ogham inscriptions exist both in Ireland and in Wales which present grammatical forms agreeing with those of the Gaulish linguistic monuments, is enough to shew that some of the Celts of these islands wrote their language before the 5th c., the time at which Christianity is supposed to have been introduced into Ireland.' It has been observed by Dr Graves, on the other hand, that there are many points of resemblance between the Oghams of the Celts and the Runes of the Norsemens; and, indeed, one Irish MS. asserts that the Oghams came to Ireland from Scandinavia :

'Hither was brought, in the sword sheath of Lochlann's king,
The Ogham across the sea. It was his own hand that cut it.'

The Ogham is said to have been in use so recently as the middle of the 17th c., when it was employed in the correspondence between King Charles I. and the Earl of Glamorgan.

The best account of Oghams is in the papers in the *Transactions of the Royal Irish Academy*, by Dr Graves, now bishop of Limerick, vol. iv. pp. 70, 173, 183, 254; vol. v. pp. 234, 401; vol. vi. pp. 71, 209, 248, where also are some papers of value on the same subject by Mr Samuel Ferguson; and the *Catalogue of the Museum of the Royal Irish Academy*, pp. 134—140; and in Mr Whitley Stokes's *Three Irish Glossaries*, pp. 55—57, compared with Thomas Innes's *Critical Essay on the Ancient Inhabitants of Scotland*, vol. ii. pp. 440—466. The reader may also consult with advantage Astle's *Origin and Progress of Writing*, Petrie's *Essay on the Round Towers of Ireland*, John Stuart's *Sculptured Stones of Scotland*, Ware's *Antiquities of Ireland*, and Braas's *Ogam-inscribed Monuments of the Gaedhil*. Ogham inscriptions may be seen in the Museum of the Royal Irish Academy at Dublin, in the Edinburgh Antiquarian Museum, and in the British Museum.

O'GIVES, the arches in pointed Gothic vaulting which cross the vault diagonally from one angle to another.

O'GOBAI. See SUPP., Vol. X.

OGY'GES, the earliest king of Attica and Boeotia named in Greek legend. In his time (according to Larcher, about 1759 B.C.) a great flood took place, called the Ogygian Flood, which desolated all the lower districts of both countries, and destroyed their inhabitants. The different legends lead to the supposition that under O. an Egyptian colony came to Boeotia, and thence to Attica. From him Boeotia took the name of Ogygia.

OGY'GIA, a genus of Trilobites peculiar to the Llandello flags of the Lower Silurian period. Six species have been described.

Ogygia Buchii.

OHIO, one of the United States of America, lies between lat. 38° 17'—41° 54' N., and long. 80° 34'—84° 40' W.; 225 miles in extent from east to west, and nearly 200 miles from north to south; containing 41,060 square miles, or 26,278,400 acres; bounded N. by Michigan and Lake Erie, E. by Pennsylvania and Virginia, from which it is separated by the Ohio River, which also

forms its southern boundary, separating it from Virginia and Kentucky, and W. by Indiana. The Ohio River forms its boundary for 436 miles, and its lake shore is 230 miles. The high table-lands hilly, and in parts mountainous regions of O., are drained by numerous rivers, among which are the Great and Little Miami, Scioto, and Muskingum, affluents of the Ohio; and the Maumee, Sandusky, Huron, Vermillion, Cuyahoga, and Ashtabula, which empty into Lake Erie. Drift formations prevail in the north, alluvium in the south, with extensive coal-measures, and limestone strata, shales, marls, and gypsum, giving the whole state a wonderful fertility. The coal-beds of Eastern Ohio cover 10,000 square miles. From 1872 to 1880, the annual produce of iron has ranged from 400,000 to about 450,000 tons. The annual produce of rock oil reaches 1,000,000 barrels; of salt, 4,500,000 bushels. In the north are valuable deposits of buhrstone, a fossiliferous flinty quartz, used for millstones. The soil, rich everywhere, is so fertile in the river bottoms as to have borne heavy cereal crops fifty successive years without manuring; the climate is temperate, with a liability to a cold in winter reaching sometimes to 20° below zero. It is healthy, except low-lands liable to fever and ague. The forests are rich in oak, black walnut, maple, &c.; the chief agricultural productions are Indian corn, wheat, rye, oats, hay, sorghum, tobacco, hemp, peaches, apples, grapes, cattle, sheep, swine, the latter being one of its chief exports. The chief manufactures are iron, clothing, furniture, spirits, wines, cotton, and woollen. The wine called Catawba, produced upon the southern shore of Lake Erie, compares very favourably with the similar wines of the Rhine. After New York and Pennsylvania, O. is the most important manufacturing state in the Union, having in 1880 had 20,700 manufactories (very few are cotton mills). Farms occupy 24,600 acres; and O. is the third wheat-producing state. A large commerce is carried on by the Ohio River, the lakes, canals, and numerous railways. The state is organised in 88 counties. The chief towns are Cincinnati, Cleveland, Columbus (the capital), Sandusky, Zanesville, &c. The state revenue in the year ending Nov. 15, 1882, amounted to 5,112,975 dollars. In 1880 there were over 12,000 educational establishments, 10 being called universities, and 22 colleges. Of these only 8 have 200 students, and only 5 are undenominational. It is currently said that O. has more colleges than all New England; it also possesses extensive libraries, and has 60 daily and 600 weekly newspapers. In 1880, 5000 miles of railway were open for traffic.

O. was organised and admitted as a state in 1803. The population in 1800 was 45,365; (1820) 581,434; (1840) 1,519,467; (1860) 2,339,599, of whom 111,257 were Germans, 51,562 Irish, 36,000 English and Scotch; (1870) 2,675,468; (1880) 3,193,062.

OHIO, a river of the United States of America, called by the French explorers, after its Indian name, *la Belle Rivière*, next to the Missouri, the largest affluent of the Mississippi, is formed by the union of the Alleghany and Monongahela, at the western foot of the Alleghanies, at Pittsburgh, in Pennsylvania, and flows west-south-west 975 miles, with a breadth of 1200 to 3000 feet, draining, with its tributaries, an area of 214,000 square miles. In its course it separates the northern states of Ohio, Indiana, and Illinois from the southern states of Virginia and Kentucky. The principal towns upon its banks are Cincinnati, Louisville (where there are rapids of 22 feet in a mile, with a steam-boat canal). Wheeling, Maysville, and Pittsburgh and Cairo. It is usually navigable from Pittsburgh, but for larger steamers in summer only from Wheeling.

OHM, GEORG SIMON, a German physicist, was born at Erlangen, 16th March 1787, was professor of Physics at Nürnberg and at Munich, and died 7th July 1854. He devoted himself mainly to the study of the galvanic current, and in 1825 published his discovery of the law which forms the basis of the mathematical theory of electricity. After him this is named *Ohm's Law* (see GALVANISM, Vol. IV., page 604). The unit of resistance fixed on by the British Association is called an *ohm*; and a million ohms, a *megohm*.

OÏDIUM. See SUPP., Vol. X.

OIL-CAKE, the cake which remains in the press, when seeds are crushed to express the oil which they contain. Oil-cake still retains a portion of the oil of the seed, along with almost all its other constituents, and is valuable either for feeding cattle or for manure. *Linseed-cake* is so much more largely used in Britain than any other kind, that the name oil-cake is in general exclusively appropriated to it, the other kinds being known as *Rape-cake*, *Poppy-cake*, *Hemp-cake*, *Cocoa-cake*, &c., according to the plant from the seed of which they are produced. The use of oil-cake for feeding cattle has very much increased of late years, and it is an article of commercial importance. Large quantities are imported into Britain from different parts of the continent of Europe, and from North America. But *English Linseed-cake*—cake made at oil-mills in England, mostly from imported seed—is preferred to any other, because heat not being so freely applied during the expression of the oil, more oil is left in the cake, and also because foreign cake often suffers from dampness both before and during the sea passage. Besides the oil which remains in it, linseed-cake contains from 24 to 33 per cent. of nitrogenous substances or protein compounds, which make it very valuable both for feeding cattle and for manure. The value of linseed-cake for feeding is greater than that of any kind of grain or pulse. *Rape-cake* is, next to linseed-cake, the kind of oil-cake best known in Britain. It is much cheaper than linseed-cake, but is not relished by cattle, having a hot taste, and a tendency to become rancid. Sheep, however, eat it readily, and it is often employed for fattening them. It is often also ground to a coarse powder (*rape-dust*), and used as a manure. Its fertilising power is great, and it is used by the Flemish farmers as guano now is by those of Britain. *Cotton Seed-cake* is much used as a manure in some parts of North America. *Cocoa-nut-cake* is used in the south of India, both for feeding cattle and for manure. Other kinds of cake are noticed, if sufficiently important, under the plants from which they are derived. Their properties are generally similar to those of linseed-cake, although the pungency of some, as *Mustard-cake*, renders them unsuitable for feeding cattle. See OILS.

OIL PALM (*Elæis*), a genus of palms, of the same tribe with the cocoa-nut palm. The best known species, the O. P. of tropical Africa, sometimes attains a height of 60—80 feet. The stems are thickest in the middle, tapering chiefly upwards. The leaves are pinnate, their footstalks spiny. The flowers have a strong peculiar smell, like that of anise or chervil. The fruit forms an immense head, like a great pine-apple, consisting of a great number of bright orange-coloured drupes, having a thin skin, an oily pulp, and a hard stone. The pulp of the drupes, forming about three-fourths of their whole bulk, yields, by bruising and boiling, an oil, which when fresh has a pleasant odour of violets, and when removed into colder regions acquires the consistency of butter. This oil is now very largely imported from tropical Africa into Britain, and is

much used for many purposes, as for making candles, toilet soaps, &c., and for lubricating machinery and the wheels of railway carriages. When fresh, it is eaten like butter. See OILS. The nut was formerly rejected as useless after the oil had been obtained from the fruit; but from its kernel a fixed oil is now extracted, called PALM-NUT OIL; which is clear and limpid, and has become to some extent an article of commerce. The O. P. abounds in mangrove swamps, but is also a conspicuous feature

Oil Palm.

(Copied from Livingstone's *Travels in Central Africa*.)

of the landscape on sandy coasts in the tropical parts of Western Africa. It yields from its trunk abundance of a pleasant and harmless beverage, which, however, becomes intoxicating in a few hours; called *Malova* in Angola, and much used there as an alcoholic stimulant. The unripe nuts of the O. P. are used in some parts of Africa for making an excellent kind of soup. The O. P. has been introduced into some parts of America, and is now abundant in them.

OIL-REFINING. Several oils, from the mode of their extraction, are necessarily impure, and various means are taken for refining or purifying them: thus, the so-called *fish-oils*—that is, whale, seal, cod, &c.—are clarified either by mixing them with a chemical solution, or by passing steam through them and filtering through coarse charcoal. The chemical solutions employed are various. One method is, to use a strong solution of oak bark, the tannic acid in which combines with the albuminous matters present in the oil, and precipitates them; another plan is, to agitate bleaching-powder, formed into a milk with water, with the oil; and then, after subsidence of the chloride of lime and water, to wash the oil with water, or jets of steam passed through it. A more simple and very effective plan, invented by Mr Dunn, is to apply a steam heat not exceeding 200° F., and then pass a current of air of the same temperature through it continuously for some time: this effectually bleaches the oil.

Olive, and some other vegetable oils, are refined by agitating them with a saturated solution of caustic soda. This renders the whole soapy; but after a time the oil precipitates a saponaceous deposit, and the remainder becomes quite clear and pure, and is then poured off. The value of several of the most important oils of commerce is so greatly increased by refining, that this art has now become a very important branch of business, and is carried out on a large scale.

OILS (including Fats). The fats and fixed oils constitute an important and well-marked group of organic compounds, which exist abundantly both in the animal and vegetable kingdoms. They are not simple organic compounds, but each of them is a mixture of several such compounds to which the term *glycerides* is applied; and the glycerides which by their mixture in various proportions form the numerous fats and oils are mainly those of palmitic, stearic, and oleic acids—if we adopt the recent view that Margarinic Acid (q. v.) has no independent existence—and to a less extent those of other fatty acids, which will be presently noticed, such as butyric, caproic, caprylic, and capric acids, which are obtained from butter; myristic acid, which is obtained from cocoa-nut oil, &c. The members of this group may be solid and hard, like suet; semi-solid and soft, like butter and lard; or fluid, like the oils. The solid and semi-solid are, however, generally placed together and termed fats, in contradistinction to the fluid oils. The most solid fats are readily fusible, and become reduced to a fluid or oily state at a temperature lower than that of the boiling-point of water. They are not volatile, or, in other words, they cannot be distilled without decomposition, and it is not until a temperature of between 500° and 600° is reached that they begin nearly simultaneously to boil and to undergo decomposition, giving off acrolein (an acrid product of the distillation of glycerine) and other compounds. In consequence of this property, these oils are termed *fixed oils*, in contradistinction to a perfectly separate group of oily matters, on which the odorous properties of plants depend, and which, from their being able to bear distillation without change, are known as *volatile oils*. These, which are also known as *essential* or *etheral oils*, differ *in toto* in their chemical composition from the compounds we are now considering, and will be separately noticed in the latter part of this article. All the fats and oils are lighter than water, and are perfectly insoluble in that fluid. Their specific gravity ranges from about 0.91 to 0.94. They dissolve in ether, oil of turpentine (one of the volatile oils), benzol, and to a certain extent in alcohol; while, on the other hand, they act as solvents for sulphur, phosphorus, &c. If a fatty matter be shaken with a watery solution of albumen, gum, or some other substance that increases the density of the water, and renders it viscid, the mixture assumes a milky appearance, in consequence of the suspension of the fat or oil in the form of microscopic globules, and is termed an *emulsion*. These bodies possess the property of penetrating paper and other fabrics, rendering them transparent, and producing what is well known as a greasy stain. They are not readily inflammable unless with the agency of a wick, when they burn with a bright flame. In a pure and fresh state they are devoid of taste and smell, but on exposure to the air they become oxidised and acid, assume a deeper colour, evolve a disagreeable odour, and are acrid to the taste; or, in popular language, they become *rancid*. The rapidity with which this change occurs is considerably increased by the presence of mucilaginous or albuminous bodies. The rancidity may be removed by shaking the oil in hot water in which a little hydrated magnesia is suspended.

The general diffusion of fats and oils in the animal kingdom has been already described. (See FATS, ANIMAL.) In the vegetable kingdom they are equally widely distributed, there being scarcely any tissue of any plant in which traces of them may not be detected; but they are specially abundant in the seeds. The seeds of the *cruciferae* are remarkably rich in oil; linseed yielding fully 20 per cent., and

rape-seed about 40 per cent. of oil; and some fruits, as those of the olive and oil-palm, yield an abundance of oil.

The uses of the oils and fats are numerous, and highly important, various members of this group being extensively employed as articles of food, as medicines, as lubricating agents, in the preparation of soaps, plasters, ointments, varnishes, pigments, candles and other means of illumination, for the purpose of dressing leather, &c. The following are the most important members of the group:

1. *Vegetable Fats*.—The chief solid fats of vegetable origin are cocoa-nut oil, nutmeg butter, and palm oil. The fluid vegetable fats or oils are divisible into the *non-drying* and the *drying oils*; the latter being distinguished from the former by their becoming dry and solid when exposed in thin layers to the air, in consequence of oxygenation; while the former do not absorb oxygen, but are converted by hyponitric acid or sub-oxide of mercury into elaidine (as described in the article *OLEINE*), a reaction which is not exhibited by the drying oils. Some of the drying oils, especially linseed oil, when mixed with cotton, wool, or tow, absorb oxygen so rapidly, and consequently become so heated as to take fire, and many cases of the spontaneous combustion of heaps of oily materials that have been employed in cleaning machinery have been recorded. The drying property may be much increased by treating the oils with a little litharge or oxide of manganese, and linseed oil thus treated is then known as *boiled oil*. The chief non-drying oils are olive oil, almond oil, and colza oil; while the most important drying oils are those of linseed, hemp, poppy, and walnut; castor oil seems to form a link between these two classes of oils, since it gradually becomes hard by long exposure to the air.

2. *Animal Fats*.—The chief solid fats are suet, lard, butter, goose grease, &c.; while among the fluid fats or oils, sperm oil, ordinary whale oil, cod-liver oil, and neat's-foot oil may be especially mentioned. In many of their characters, spermaceti and bees-wax resemble the solid fats, but, as will be shewn in the articles on these subjects, they are not glycerides. As a general rule, stearine and palmitine, both of which have comparatively high fusing points (between 157° and 114°), preponderate in the solid fats; while oleine, which is fluid at 32° , is the chief constituent of the oils.

One or two of the most important of the decompositions of the fats must be noticed. When any of these bodies are heated with the hydrated alkalies, they undergo a change which has long been known as *Saponification*, or conversion into soap (q. v.), in which the fatty acid combines with the alkali to form a *soap*, while the sweet viscid liquid glycerine is simultaneously formed. The combination of a fatty acid with oxide of lead forms a *plaster*. For further details on these points, the reader is referred to the articles *SOAP* and *PLASTERS*.

The process of saponification affords a ready means of isolating the fatty acids, as the stearic or oleic acid may be at once separated from an alkaline stearate or oleate by the addition of hydrochloric or tartaric acid. When the fatty acids are, however, required on a large scale, as for the manufacture of the so-called stearine candles, which in reality consist mainly of stearic and palmitic acids, sulphuric acid and the oil or fat are made to act upon each other at a high temperature. See *CANDLE*. The fatty acids may also be procured in a very pure form by the injection of superheated steam at a temperature of between 600° and 600° into heated fat—a process which, according to Professor Miller, 'from its simplicity and from the purity of the products which it yields, bids fair to

supersede those previously employed in the preparation of the fatty acids for illuminating purposes.'

The only fatty acids which have been specially mentioned in this article are those which occur in natural glycerides, such as stearic, palmitic, and oleic acids. The term *fatty acid* has, however, in Chemistry a wide signification, and is applied to many acids homologous to stearic acid, but not occurring in any natural fats or oils. Thus stearic acid may be taken as the type of a group of acids (of which seventeen are already known) represented by the general formula, $C_{n+1}H_{2n+2}O_2$, commencing with formic acid ($C_1H_2O_2$), including acetic, propionic, butyric, valeric (or valerianic), caproic, capanthylic, caprylic, pelargonic, capric, lauric, myristic, palmitic, stearic, arachidic, and cerotic acids, and terminating with melissic acid ($C_{26}H_{52}O_2$). These are divided into the volatile and the true (or solid) fatty acids; the volatile acids being those from formic to capric acid, while the remainder, beginning with lauric acid, are the true fatty acids. The *volatile fatty acids* are fluid, and for the most part oily at ordinary temperatures, may be distilled without change, possess a pungent odour, and are acrid to the taste, and their solutions redden litmus paper strongly. The *true fatty acids*, on the other hand, are solid at ordinary temperatures, are devoid of taste and smell, cannot be distilled, except *in vacuo*, without decomposition, and only exert a slight action on litmus. The volatile acids occur in the animal and vegetable kingdoms (formic acid, for example, in red ants, and valeric acid, in the root of valerian), and they are likewise produced by the oxidation and spontaneous decomposition of numerous animal and vegetable products. The entire series, up to capric acid, may be obtained by oxidising oleic acid with nitric acid. The true or solid acids only occur as constituents of animal and vegetable fats.

Some chemists make a second group of fatty acids, of which oleic acid is the type, and which have the general formula $C_nH_{2n-2}O_2$; but Oleic Acid (q. v.) is the only member of this group which is of any practical importance.

A complete list of even the chief fats and fixed oils would take up far more space than we can command. Many of the principal oils are noticed in separate articles, as Almond Oil, Castor Oil, Croton Oil, and some account given of their properties and uses; or under the names of the substances from which they are procured, as Linseed, Rape, Candle-nut. The British pharmacopœia contains hog's lard, mutton suet, cod-liver oil, concrete oil (or butter) of nutmeg, and almond, castor, croton, linseed, and olive oils, besides the closely allied substances spermaceti and wax.

The *Volatile or Essential Oils* exist, in most instances, ready formed in plants, and are believed to constitute their odorous principles. They form an extremely numerous class, of which most of the members are fluid; a few (oil of aniseed, for example) being solid at ordinary temperatures, but all of them are capable of being distilled without undergoing change. They resemble the fixed oils in their inflammability, in their solubility in the same fluids, and in their communicating a greasy stain to paper or any other fabric; but the stain in this case soon disappears, and they further differ in communicating a rough and harsh rather than an unctuous feeling to the skin. Their boiling points are in almost all cases far higher than that of water, but when heated with water, they pass off with the steam—a property on which one of the chief modes of obtaining them depends. See *PERFUMERY*. The oils have characteristic penetrating odours, which are seldom so pleasant as those of the plants from which they are obtained, and their taste is hot and irritating.

They vary in their specific gravity, but most of them are lighter than water, and refract light strongly. Most of them are nearly colourless when fresh, but darken on exposure to light and air; but a few are green, and two or three of a blue colour. By prolonged exposure they absorb oxygen, and become converted into resins.

By far the greater number of them are products of the vital activity of plants, in which most of them exist ready formed, being enclosed in minute cavities, which are often visible to the naked eye. Although diffused through almost every part of a plant, the oil is especially abundant in particular organs of certain families of plants. In the *Umbellifera*, it is most abundant in the seeds; in the *Rosaceae*, in the petals of the flowers; in the *Myrtaceae* and *Labiata*, in the leaves; in the *Aurantaceae*, in the rind of the fruit. As in the case of the animal and vegetable fats and fixed oils, so most of the essential oils occurring in plants are mixtures of two or more distinct chemical compounds, one of which usually contains no oxygen, while the others are oxidised. Of these, the former, which is a pure hydrocarbon, is the more volatile, and acts as a solvent for the others. Most of these oils, when cooled, separate into a solid and a fluid portion, to which the terms *Stearopten* and *Elæopten* have been applied.

In the comparatively few cases in which the oils are not formed naturally, they are produced by a species of fermentation, as in the case of Oil of Bitter Almonds and Oil of Mustard (q. v.), while others are the product of the dry distillation or of the putrefaction of many vegetable bodies. Some of the natural oils, as those of cinnamon, spirea, and winter-green, have also been artificially produced.

The essential oils are much employed in the fabrication of Perfumery (q. v.), for the purpose of flavouring liqueurs, confectionary, &c., for various purposes in the arts (as in silvering mirrors), and in medicine. The special uses of the most important of these oils in medicine will be noticed subsequently.

The members of this group, which is an extremely numerous one (between 100 and 200 essential oils being noticed in works devoted to the specific treatment of this subject), admit of arrangement under four heads. 1. Pure Hydrocarbons; 2. Oxygenous Essential Oils; 3. Sulphurous Essential Oils; 4. Essential Oils obtained by Fermentation, Dry Distillation, &c.

1. The *Pure Hydrocarbons* are for the most part fluid, and have a lower specific gravity, a lower boiling point, and a higher refractive power than the oxygenous oils. They absorb oxygen, and are converted into oxygenous oils and resins. They may be separated from oxygenous oils, with which they are usually associated, by fractional distillation. They include oil of turpentine ($C_{10}H_{16}$), and the oils of bergamot, birch, chamomile, caraway, cloves, elemi, hop, juniper, lemons, orange, parsley, savine, and valerian, most or all of which contain the same hydrocarbon as Oil of Turpentine (q. v.), and in addition to it an oxidised compound; oil of copaiba ($C_{10}H_{16}O$), attar of roses ($C_{15}H_{26}$), &c.

2. The *Oxygenous Essential Oils* may be either fluid or solid, the latter being also termed *Camphora*. A *stearopten* separates from most of the fluid oils on cooling. They are more soluble in water and spirit of wine than the pure hydrocarbons. They may be divided into (1.) those which are fluid at ordinary temperatures, such as those of aniseed, chamomile,* cajeput, caraway,* cinnamon, cloves,* fennel, lavender, peppermint, rue, spirea, thyme,* winter-green, &c. Those marked with a (*) are associated with the pure hydrocarbons already

described. (2.) The camphors, such as ordinary camphor ($C_{15}H_{10}O_2$), Borneo camphor ($C_{15}H_{18}O_2$), &c.

3. The *Sulphurous Essential Oils* are chiefly obtained from the *Crucifera*. They probably all contain the radical *allyl* (C_3H_5). The oils of garlic and of mustard (both of which have been described in special articles), and those of horse-radish, scurvy-grass, and asafetida, are the best illustrative of this division.

4. Amongst the essential oils obtained by fermentation, dry distillation, &c., may be mentioned the oils of bitter almonds and of black mustard, the oils of milfoil, plantain, centaury, &c. (whose leaves have no smell until they have been moistened for some time with water, when a kind of fermentation is set up, and oil is yielded in abundance), Furfuramide (q. v.), &c.

The British pharmacopoeia contains the essential oils of anise, cajeput, caraway, chamomile, cinnamon, cloves, copaiba, coriander, cubeba, dill, juniper, lavender, lemon, nutmeg, peppermint, pimento, rosemary, rue, savine, spearmint, and turpentine. Of these, the oils of anise, cajeput, caraway, chamomile, coriander, dill, peppermint, pimento, and spearmint are used as stimulants and antispasmodics in cases of flatulence, griping, &c.; and to disguise the nauseous taste of various medicines. The oils of cajeput, cinnamon, and rue act similarly but more powerfully. The oils of copaiba and cubeba act in the same manner as the substances from which they are derived; oil of juniper is a powerful diuretic, and oil of savine (and to a less extent oil of rue) an emmenagogue. The oils of lavender and lemon are used to conceal the smell of sulphur ointment, and to give an agreeable odour to lotions, &c. The oil of rosemary is chiefly employed as a stimulating liniment, especially in cases of baldness; and the oil of nutmeg is seldom given medicinally except in the form of aromatic spirit of ammonia, into the composition of which it enters.

Essential oils for flavouring are by no means always derived from the substances of which they are intended to communicate the flavour. Thus an essential oil indistinguishable (or nearly so) from that of pine-apples may, by recent methods, be obtained from butyric acid, a product of rancid butter or putrid cheese; and a very serviceable 'essence of pears' is procured from the offensive fusel oil.

Bland oils—such, for example, as olive oil—were much used by the ancients as external applications in various forms of disease. Celsus repeatedly speaks of the use of oil applied externally with friction in fevers, and in various other diseases. Pliny says that olive oil warms the body and at the same time cools the head, and that it was used with these objects previously to taking cold baths. Aretæus recommends a sitz-bath of oil in cases of renal calculi, and Josephus relates that a similar mode of treatment was employed in the case of Herod. Galen prescribed 'oil and wine' for wounds in the head; and the parable of the good Samaritan affords additional evidence that this was a common mode of treating wounds. The use of oil preparatory to athletic exercises is referred to by numerous Greek and Latin writers.

As a cosmetic—that is to say, as a means of giving to the skin and hair a smooth and graceful appearance—its use has been prevalent in hot climates from the earliest times. There is abundant historical evidence of this usage of oil amongst the Egyptians, the Jews, the Greeks, and the Romans; and Pliny's statement that butter is used by the negroes, and the lower class of Arabs, for the purpose of anoint-

ing, is confirmed by the observation of all recent African travellers. In hot climates, there is doubtless a practical as well as an æsthetic object in anointing. The oil, being a bad conductor of heat, affords a certain amount of protection against the direct action of the solar heat; it is likewise serviceable as a protection against the attacks of insects, and as a means of checking excessive perspiration. The fact of oily and fatty matters being bad conductors of heat, serves also to explain why the Esquimaux and other dwellers in Arctic regions have recourse to the inunction of the blubber, &c. In their case the oily investment serves to prevent the escape of the bodily heat.

The Greeks and Romans not only employed oil for the purposes already mentioned, but in their funeral rites; the bodies of their dead being anointed with oil, with the view probably of postponing incipient decomposition. A similar practice existed amongst the Jews, and in the Gospels we find various passages in which our Lord referred to his own body being anointed by anticipation. It appears from the evidence of St Chrysostom, and other writers, that this ancient usage of anointing the bodies of the dead was long retained in the Christian Church. See UNCTION; EXTREME UNCTION.

In conclusion, we may remark that the ancient system of anointing, as a means of medical treatment, has to a certain extent been revived in modern times. Many physicians of the present day combine the inunction of cod-liver oil with its internal administration, a combination first recommended by Professor Simpson of Edinburgh; and Sir Henry Holland advocates the practice of anointing the harsh, dry skin of dyspeptic patients with warm oils. There can, we think, be little doubt that there are many forms of disease in which the local application of medicinal oils may be advantageous.

The *mineral oils* will be found discussed under the heads of NAPHTHA, PARAFFIN, PARAFFIN OIL, SHALE, and OIL-WELLS AND OIL-TRADE in SUPP., Vol. X.

OILS IN THEIR COMMERCIAL RELATIONS.—The solid animal oils found in commerce are butter and lard, tallow, mares' grease, goose grease, neats-foot oil, and unrefined yolk of egg oils. The two first are fully described under their names. See BUTTER, LARD. Tallow is the fat of oxen and sheep, but more especially the fat which envelops the kidneys and other parts of the viscera, rendered down or melted. The qualities of this solid oil render it particularly well adapted for making candles, and until the end of the first quarter of the present century, candles for ordinary use were almost wholly made of it, the high price of wax and spermaceti preventing their employment except by the most wealthy and for ecclesiastical purposes. Besides its use in making candles, tallow is most extensively used in the manufacture of soap, and for the purpose of preserving machinery from rust. The trade in tallow with Russia, which produces the best, and with North and South America, and even with India and other countries, is very considerable; but it is declining, owing of course to the extension of gas and the enormous development of the Paraffin and Petroleum Oils (q. v.), and other light-giving materials. The quantities of tallow and stearine imported in five recent years into Britain were as follows:

	Tons.	Value
1871,	1,247,064	£2,996,258
1872,	1,232,144	" 2,792,670
1873,	1,537,891	" 3,947,271
1874,	1,155,243	" 4,172,113
1875,	967,896	" 4,358,166

The chief use of tallow in this country is now in the manufacture of Soap (q. v.), and even in this it

has yielded in importance to palm and cocoa-nut oils.

Mares' Grease is not nearly so solid as tallow, it is a yellowish-brown grease, imported extensively from Monte Video and Buenos Ayres, where vast numbers of horses are slaughtered for their hides, bones, and grease; it is particularly valuable as a lubricant for machinery, and is chiefly employed for that purpose after much of its stearine has been removed for candle-making. The reason this material is called *mares' grease*, is said to be from the circumstance, that in South America horses are chiefly used alive, and mares are slaughtered as comparatively useless. Goose Grease is another soft fat, much valued by housewives for many purposes, but excepting that it is sold in some districts as a remedial agent, it has no commercial importance. Neats-foot Oil is a soft fat procured in the preparation of the feet and intestines of oxen for food as sold in the tripe-shops. The quantity obtained is not very great, but it is in much request by curriers for dressing leather. Yolk of Egg Oil is a hard oil, which, though little known in Britain, is extensively used in other countries where eggs are cheaper. In Russia, for instance, it is manufactured on so large a scale as to supply some of the largest makers of fancy soaps, and it forms the principal material in the celebrated Kasan Soap; and certain pomades are made of it which have a great reputation, and realise very high prices. This oil is not unlike palm oil in colour and consistency; but when refined is liquid, and has a reddish-yellow colour. Its price at Moscow is as high as 8s. per lb.

The liquid animal oils are more numerous, and, excepting tallow, are far more important, the so-called fish-oils being the principal. These are whale, porpoise, seal, cod, herring, shark, &c. The whales which are pursued for their oil are: (1.) The Sperm Whale. This huge creature is from 60 to 70 feet in length, and yields generally from 5000 to 6000 gallons of oil. The finest oil is taken from the great reservoir on the head. The oil of this species is all of a quality superior to others, and is known as sperm oil. For the method of procuring this oil, see CACHOLOT. (2.) The Right Whale, which yields by far the largest proportion of whale oil. This, with that yielded by other less important species, is usually called train oil. The term *train* is supposed to be a corruption of *drain*, and applies to the circumstance of the oil being drained out of the blubber; and in this sense it is also applied to sperm oil from the blubber of the cacholot, in contradistinction to the finer oil from the head matter. The Right Whale forms the chief object of the northern fisheries, but other species of *Balaenæ* are pursued in different parts of the world for the sake of their oil. See WHALE.

Amongst the smaller Cetaceans, the porpoises—called also dolphins ('puffydunters' on the east coast of Scotland)—and grampuses yield an excellent oil, second only in value to that of regular oil whales; and to obtain it, large numbers are occasionally killed in the British seas. The price of sperm oil ranges from £80 to £95 per tun, and that of ordinary train oil from £40 to 45 per tun of 252 gallons. The imports and consumption of the various kinds of whale oil for the five years 1871–1875 were as follows:

	Tons.	Value
1871,	24,679	£1,087,734
1872,	18,719	" 855,690
1873,	17,686	" 766,927
1874,	17,051	" 751,359
1875,	19,369	" 917,701

A large quantity of very valuable oil is obtained

from Seals, and the seal-fishery, as a means of obtaining oil, is only second in importance to that of the whale. It is carried on chiefly on the shores of Newfoundland, Greenland, and Labrador. Like the whales, the seals have a thick layer of blubber, in which the oil is contained. See SEAL. The first draining from the blubber is of a fine clear pale-straw colour; the next, yellow or tinged; and the last is brown or dark. The price ranges in our markets at about £35 to £40 per tun for pale, £30 to £35 for yellow, and £28 to £30 for brown. The whale and the seal oils are nearly all used for burning in lamps, and for this purpose they are admirably adapted by their great illuminating power. They are also the best lubricants for machinery.

Of the true fish oils, that from the cod is first in importance, more especially since its medicinal properties were discovered. It is made only from the liver of the fish; and the attempt which was made to induce a popular belief that the so-called cod-liver oil was different from the ordinary cod oil of commerce, was simply a cheat; no difference exists, and the oil is obtained just as good from the oil merchant, at a moderate price per gallon, as from the empiric at an exorbitant price per pint. Indeed, the purer the oil can be got, the better it is in a remedial point of view, notwithstanding the efforts made to convince the public that a certain colour is better than any other.

Instead of the old and somewhat rude methods of preparing the oil (see COD-LIVER OIL), much more complete and efficient arrangements are now adopted. The livers, when taken from the fish, are all examined, washed in clean water, and placed in sieves to dry. Thence they are transferred to pans heated with steam, and after being exposed to a gentle heat for about three-quarters of an hour, the heat is discontinued; and when cold, the oil which has separated is skimmed off, and strained through flannel bags into tubs. Here certain impurities subside, and the clear oil is poured off from the dregs, and the contents of numerous tubs are transferred to galvanised iron cisterns, in which a further settlement takes place. The oil is now ready for the filters, which are made of the strong cloth called moselein, through which it is forced by atmospheric pressure into the store-tanks, which are also of galvanised iron. Hence it is pumped into the casks for export, which are usually hogsheds, tierces, and barrels. The value of cod-liver oil is about £34 to £40 per tun. The imports vary much according to the success of the fishery; they have reached nearly 1000 tons per annum. Besides its consumption in lamps, and for medicinal purposes, cod oil is used in making some kinds of soap. Oil is occasionally made from the herring, but not in very great quantities; it, however, forms a commercial article. It is made from the whole of the fish, the smell of which it retains to a very disagreeable extent.

The lightest of all the fixed oils is made from the liver of the common shark; it ranges from specific gravity 0.865 to 0.867. This, and the oil made from the livers of the Common Skate (*Raja batia*), the Thornback (*R. clavata*), and the White Skate (*Rhinobatus cerniculus*), are often substituted for the cod-liver oil used medicinally, but have not its valuable properties.

Under the name of lard oil, large quantities of the oleine of lard have been imported of late years from America. It is a secondary product, arising from the great manufacture of lard stearine for candle-making which has arisen in that country. Lard oil is worth about £45 to £53 per tun, and is principally used as a lubricant for machinery.

The solid vegetable fixed oils which find a place

in commerce are palm oil, cocoa-nut oil, kokum or vegetable tallow, and carapa or carap oil. The palm oil is an oil of a bright orange-yellow colour and an agreeable violet odour: it is obtained from the not very thick covering of the hard seeds of the Oil-palm (q. v.). The fruits, when gathered, are shaken out of the clusters, and are laid in heaps in the sun for a short time, after which the natives boil them slowly in water, when the oil separates and is skimmed off the surface, and carried in small quantities to the depôts of the traders, who transfer it to casks which are prepared to receive it on board the ships. The quantity thus collected is enormous. The imports into Britain alone for the five years 1876—1880 were as follows, in cwts.: (1876) 879,824; (1877) 897,264; (1878) 670,797; (1879) 881,329; (1880) 1,032,823. Previous to 1840, the chief use of palm oil was in making soap, but it was about that time found that the palmitine or fat acid of this oil was admirably adapted for the manufacture of Candles (q. v.); and since then it has become of much greater importance.

Cocoa-nut Oil is a white fat, with the peculiar smell of the kernel; it is made by grinding or pounding the kernel of the cocoa nut. After it has been boiled in water for a short time, the paste is submitted to great pressure, and a large quantity of milky juice is obtained; this is slowly boiled, and the oil separates and rises to the surface in considerable quantity, and is skimmed off. Twenty ordinary-sized nuts will yield as much as two quarts of oil. This oil is now very largely imported, and, treated in the same way as palm oil, forms a stearine, which greatly improves that of palm oil when mixed with it in proper proportions; neither does so well separately, and the consumption of cocoa-nut oil has consequently very greatly increased. Most of it comes from Ceylon, where the tree is largely cultivated on purpose. The imports in 1876 were 199,431 cwts.; in 1879, 199,991 cwts.; and in 1880, 318,454 cwts. By far the greater proportion of this vast quantity is used by the candle manufacturers, and the remainder in making common soap, its disagreeable smell preventing it being employed for the better kinds.

Vegetable Tallow, or Kokum Oil, is also used by the candle-makers; only small quantities, however, are imported. It comes from Singapore, and is produced from the seed of *Garcinia purpurea*, a species of the same genus with the mangosteen. Another kind of vegetable tallow is made in China, from the seeds of *Silingia sebifera*.

Carapa, Carap, Crab, or Andiroba Oil, is very extensively made in British Guiana and the West Indies, but it is nearly all used there, either as a pomade for preserving the hair, or as an unguent for rheumatism and neuralgic pains, for which purposes it is said to be very useful. See CARAPA.

The Bassia Oil is beginning to attract attention, and several importations have taken place from India, and some rather large quantities have reached Liverpool from Bombay, under the name of Muchwa Oil. This oil is of a soft butter-like consistence, and yellowish-green colour, and is well adapted for soap-making and for machinery grease. See BASSIA.

The liquid vegetable oils are very numerous, and several are of great commercial importance. First in rank is Olive Oil, made from the ripe fruit of the Common Olive (*Olea Europea*). When good and fresh, it is of a pale greenish-yellow colour, with scarcely any smell or taste, except a sweetish nutty flavour, much esteemed by those who use it. The finest qualities are the Provence Oil (rarely seen in Britain), Florence Oil, and Lucca Oil. These are all used for salads and for cooking. The Genoa is used on the continent for the same purposes;

and Galipoli, which is inferior, constitutes the great bulk of what is received in this country for cloth dressing, Turkey-red dyeing, and other purposes; the continental soap-makers also employ it extensively. The high price of the best qualities leads to much adulteration with poppy and other oils, but it is generally pretty safe when in the original flasks as imported. The mode of obtaining the finest kinds is by gentle pressure of the fruit. The cake is afterwards treated with hot water, from the surface of which an inferior quality is skimmed. The Galipoli oil is obtained by allowing the olives to ferment in heaps, and then to press them in powerful oil-presses; the cake or *marc* is then treated with water once or twice, until all the oil is removed; this inferior oil is darker in colour, being a yellowish or brownish green. We receive the finest from Italy, and the commoner qualities from the Levant, Mogador, Spain, Portugal, and Sicily. The present values range from £44 to £54 for common kinds, and the finest Lucca is £1 the half chest, or nearly £85 per tun measure. The total quantity imported during the four years 1877—1880 was as follows: (1877) 31,271 tuns; (1878) 20,615; (1879) 26,198; (1880) 20,260.

Nearly all the other liquid vegetable oils of this class are obtained from seeds, and as they are most of them treated in the same way, one description will suffice. First, the seeds are ground—and this in Britain is always done by vertical stones (see MILL, fig. 4)—into a kind of coarse meal, which is first warmed in pans, and then put in certain portions in woollen cloths or bags, so arranged as to be of uniform thickness; these are again wrapped in horse-hair cloths, and each parcel is placed

Fig. 1.

between two flat boards slightly fluted on their inner sides, and then placed in the wedge-press (fig. 1). In this *a*, *a* are two flannel bags filled

Fig. 2.

wedge, *g*, is lastly inserted, and the press is ready for action. The operation is very simple;

a heavy wooden stamper, from 500 to 600 pounds-weight, is raised by machinery about two feet, and allowed to fall upon the wedge *g*. This tightens all the other wedges and pressing-plates, and exerts a pressure of about 60 tons on each bag when fully driven home. The pressing-plates, *i*, *i*, *i*, *i*, are pierced with holes, and so are the plates *b*, *b*, *b*, *b*; and through these holes the oil trickles and passes away by the pipe, *k*, shewn in fig. 2.

One of the chief seed oils is that of linseed (*q. v.*). Very little linseed oil is imported into Britain; the improved machinery, and the great demand for the oil-cake (see OIL-CAKE), cause it to be manufactured at home, and at present it is exported in considerable quantities; thus, from Hull alone there was exported in 1880, of seed-oil, expressed chiefly from foreign seed, no less than 5,890,500 gallons, and over 10,000 tons of oil-cake; and from London and Liverpool together about 7,439,300. The total production of Great Britain for 1871 was estimated at 69,000 tons; and for 1872, 67,000 tons, and fluctuates from 60,000 to 70,000 tons a year. In 1880, 14,508,000 gallons of seed-oil were exported. It is worth about £36 per ton. Rape or Colza Oil is a name which covers the product of several cruciferous seeds, as rape, turnip, and other species of *Brassica*, radish, *Sinapis toria*, Gold of Pleasure, &c. The oil is clear brown and usually sweet, but with a mustard-like flavour; its illuminating powers are excellent, and it is also well adapted for wool-dressing. Very large quantities are made in Great Britain, chiefly from *Sinapis toria* and other Indian mustard seeds, which are imported under the name of Surzee Seed. The imports of these seeds are occasionally as much as 60,000 quarters per annum. Hemp Seed yields a green oil which is much used in making soft soap, especially in Holland. In Russia it is eaten with various kinds of food, and is greatly liked by all classes.

The following are the names of a number of oils which are more or less used in this country: Cotton-seed Oil. Palm-nut Oil, a clear limpid oil from the hard nut of the oil-palm; this nut was formerly rejected as useless after the oil had been obtained from the fruit. Safflower-seed Oil, from the seeds of *Carthamus tinctorius*; it constitutes the real Macassar Oil. Sunflower-seed Oil, from seed imported from the Black Sea provinces of Russia; a rapidly increasing trade is springing up in this excellent oil. Poppy-seed Oil, from the seed of *Papaver somniferum*, largely imported from India; it is as sweet as olive oil, and is extensively substituted for it, especially in France, where it is also very largely cultivated. Gingelli-seed Oil, from the seed of *Sesamum orientale*, an important Indian staple of which we are large consumers; the oil is much used for wool dressing, &c. Ground-nut Oil, from the seeds of *Arachis hypogaea*, imported from Western Africa and India; this oil is particularly adapted for fine machinery, as it is not affected by cold. Niger, Til, or Teel-seed Oil, from the seeds of *Guizotia oleifera*, much imported from Bombay. Croton Oil, from the seeds of *Jatropha curcas*, largely used in wool dressing. The Croton Oil used in medicine is from *Croton tiglium*, of which only small quantities are imported; whereas of the other 1200 or 1400 tuns, besides a quantity of the seed, often reach us in one year. Another highly valuable medicinal oil, Castor Oil (*q. v.*), is of great commercial importance. Almond Oil, chiefly used for perfumery purposes, is made from the kernels of the sweet and bitter almond; it is the most free from flavour and odour of any oil in use, notwithstanding that the essential oil of bitter almonds is so strongly flavoured.

Oils made from the seeds of the following plants

have some commercial value in other countries: *Madia sativa*; *Argemone Mexicana*; various species of Gourds; Garden Cress (*Lepidium sativum*); tobacco, now extensively used in Southern Russia, Turkey, and Austria; hazel-nuts; walnuts; nuts of stone pine; pistachio nut; tea-seed; this in China is a common painter's oil; the grape, from the seeds or stones, as they are called, saved from the wine-presses, used in Italy; Brazil-nuts (*Bertholetia excelsa*); *Calophyllum inophyllum*, called Pinnacottay Oil in India; *Melia azadirachta*, called in India by the names Neem and Margosa Oil; *Aleurites triloba*, called in India, Country Almond Oil, and much used for burning in lamps and torches; *Psoralea corylifolia*, called Baw-chee-seed Oil. The seed is sometimes imported to this country for pressing. Ben-seeds (*Moringa Pterygosperma*); Bonduc-nuts, the seeds of *Guilandina bonduc* and *G. bonducella*.

The following oils, new to European commerce, were shewn in the International Exhibition of 1862. India.—Teorah Oil, from the seeds of *Brassica erucastrum*; Capala Oil, from the seeds of *Rottlera tinctoria*; Cardamom Oil, from the seeds of *Elettaria Cardamomum*; Hidgee Badham Oil, from the seeds of *Anacardium occidentale*, or Cashew-nut, now largely cultivated in India; Cassia-seed Oil; Chaulmoogra Oil, from the seeds of *Hydnocarpus odorata*; Cheerongee Oil, from the seeds of *Buchanania latifolia*; Chemmarum Oil, from the seeds of *Amoora rohituka*; Circassian-bean Oil, from the seeds of *Adenanthra pavonina*; Hoorhoorya Oil, from the seeds of *Polanisia tocosandra*; Custard Apple-seed Oil, from the seeds of *Anona squamosa*; Exile Oil, from the seeds of *Cerbera Thevetia*; Monela-grain Oil, from the seeds of *Dolichos uniflorus*; Kanari Oil, from the seeds of *Canarium commune*; Khaliziri Oil, from the seeds of *Vernonia Anihelminthica*; Malkungunnee Oil, from the seeds of *Celastrus paniculatus*; Bakul Oil, from the seeds of *Mimusops elengi*; Rana Oil, from the seeds of *Mimusops Kaki*; Moodooga or Pulas Oil, from the seeds of *Butea frondosa*; Nahor or Nageshur Oil, from the seeds of *Mesua ferox*; Hone-seed Oil, from seeds of *Calophyllum calaba*; Poonga, Caron, or Kurmig Oil, from the seeds of *Pongamia glabra*; Vappanley Oil, from seeds of *Wrightia antidysenterica*; Babool Oil, from seeds of *Acacia Arabica*; Gamboge Oil, from seeds of the Gamboge-tree (*Garcinia pictoria*); Coodiri Oil, from the seeds of *Sterculia fetida*; Kikool Oil, from the seed of *Salvadora persica*; Marotty, Surrate, or Neeradiimootoo Oil, from the seeds of *Hydnocarpus inebrians*; and Pundi-kai Oil, from the nutmegs of *Myristica malabarica*.

From Brazil.—Oils from the seeds of *Feuillea cardifolia*, *F. monosperma*, *Anisosperma passiflora*, *Cucurbita citrullus*, *Mabea fistuligera*, *Anda gomesii*, *Myristica bicuhiba*, *Carpotroche Brasiliensis*, *Dipteris odorata*, *Theobroma cacao*, *Acrocomia sclerocarpa*, *Nectandra cymbarum*, and from the fat of the Alligator and the Tapir, all for medicinal and perfumery purposes; and oils from the seeds of *Enocarpus Bacaba*, *E. palaua*, *Caryoca Brasiliensis*, and *Euterpe edulis*, used for culinary and lighting purposes.

From British Guiana.—Oil drawn from the stem of *Oreodaphne opifera*; it resembles refined turpentine. Wallaba Oil, from the wood of the Wallaba-tree (*Eperera falcata*), medicinal. Other oils have become known at various International Exhibitions. The preparation of the essential oils is treated of under PERFUMERY.

The importance of the manufacture of oils is very great; in 1880 the value of the imports of the leading staples of this trade—viz., fish, palm, cocoa, and olive oils—was no less than £3,444,599.

The aggregate of the other kinds was £1,416,347. In addition, oil seeds to the value of about £5,500,000 are imported for crushing in Great Britain; whilst the exports of oil amount in value to about £1,600,000. Thus, it will be seen that this trade represents a capital of near £12,000,000 sterling. See OIL-VELLS and OIL-TRADE in SUPP., Vol. X.

OIRIR-GAEL, a name which, in the early times of Scottish history, was applied to the Gaels of the coasts, in contradistinction from the Gall-Gael or islesmen. There was long a struggle for superiority between these two races, represented respectively by Somerled of the Isles and the later kings of Man, in which the latter were eventually successful, uniting under one head the dominion of Argyle and the Isles.

OISE, a river of France, one of the chief affluents of the Seine, rises in the vicinity of Rocroy, in the north of the department of Ardennes, and flows south-west, joining the Seine at Conflans-Sainte-Honorine, after a course of 150 miles, for the last 75 of which it is navigable. The fall of the river is very gradual, and its course is extremely sinuous. It is connected by canals with the Somme, the Sambre, and the Scheldt, and forms one of the chief commercial routes between Belgium and Paris. It becomes navigable at Chaunty.

OISE, a department in the north of France, is bounded on the E. by the department of Aisne, and on the W. chiefly by that of Seine-Inférieure, which intervenes between it and the English Channel. Area, 2250 square miles, of which two-thirds are in arable land; pop. (1881) 404,555. The principal rivers are the Oise—from which the department derives its name—and its tributaries the Aisne and Therain. The department is almost wholly included in the basin of the Oise; and as the course of that river indicates, the surface—consisting for the most part of extensive plains—has a general slope toward the south-west. The soil is in general fertile, and agriculture is well advanced. The products are the usual grain-crops, with an immense quantity of vegetables, which are sent to the markets of the metropolis. The department is divided into the four arrondissements of Beauvais, Clermont, Compiègne, Senlis; capital, Beauvais.

OITI (*Mouquilea tomentosa*), a tree of the natural order *Chrysobalanaceae*—by many botanists regarded as a suborder of *Rosaceae* (q. v.)—a native of the north of Brazil, and valuable on account of its timber, which is very good for ship-building.

O'KA, an important commercial river of Central Russia, the principal affluent of the Volga from the south, rises in the government of Orel, and flows in a generally north-east direction, forming a common boundary between the governments of Tula, Kaluga, and Moscow; and afterwards flowing through the governments of Riazan, Vladimir, and Nijni-Novgorod. It joins the Volga at the city of Nijni-Novgorod, after a course of 837 miles. Its basin, estimated at 127,000 square miles in extent, comprises the richest and most fertile region of Russia. The principal towns on its banks are Orel, Beleff or Bieleff, Kaluga, Riazan, and Murom; the most important affluents are the rivers Moscow, Kliasma, and Tzna. During spring, the Oka is navigable from Orel to the Volga; but in summer the navigation is obstructed by sandbanks. It communicates with the ports on the Baltic, Caspian, and White Seas; and the cargoes annually shipped down the river amount in value to several million pounds sterling.

O-KEE-CHO-BEE, a lake bordering on the Everglades of Southern Florida (see FLORIDA), about 120 miles in circuit, receiving several small rivers,

and having for its outlet the river Caloo-sa-hatchee, which flows westerly into the Gulf of Mexico.

OKEN (originally OCKENFUSS), LORENZ, a celebrated German naturalist, was born at Bohlsbach, in Würtemberg, August 1, 1779. He studied at Würzburg and Göttingen; became extra-ordinary professor of medicine at Jena in 1807, where his lectures on natural philosophy, natural history, zoology, comparative anatomy, vegetable and animal physiology, attracted much notice. In 1812, he was appointed ordinary professor of natural science; and in 1816, commenced the publication of a journal partly scientific and partly political, called *Iris*, which continued to appear till 1843. The opinions promulgated in the *Iris* led to government interference, and O. resigned his chair, and became a private tutor, devoting his leisure to the composition of works on natural history. In 1823, he obtained a professorship in the newly-established university of Munich; but in 1832, exchanged it for another at Zürich, where he died, 11th August 1851. O. aimed at constructing all knowledge *a priori*, and thus setting forth the system of nature in its universal relations. The two principal works in which this idea is developed are his *Lehrbuch der Naturphilosophie* (Jena, 1808—1811), and his *Lehrbuch der Naturgeschichte* (3 vols. Leip. 1813—1827). The former has been translated into English, and published by the Ray Society under the title of *Elements of Physio-philosophy*. As O.'s philosophic system of nature was very peculiar, and quite unlike anything that had preceded it, O. invented a nomenclature of his own, which, however, in many cases is forced and pretentious, composed for the most part of new-coined words, and difficult to remember. It therefore found little favour, and O. was long regarded—particularly by French and English savans—as a mere dreamer and transcendental theorist; nor can it be denied that he is largely such, infected with the worst vices of the school of Schelling, to which he belonged; but some of his 'intuitions'—if we may so term his scientific suggestions—were remarkably felicitous, and in the hands of rigorous demonstrators, have led to great results. In his work *Die Zeugung* (On Generation, Bam. 1805), he first suggested that all animals are built of vesicles or cells; in his *Beitrage zur vergleichenden Zoologie, Anatomie und Physiologie* (1806), he pointed out the origin of the intestines in the umbilical vesicle; and in the same year lighted accidentally upon the idea, since so prolific of results, that the bones of the skull are modified vertebrae. On account of this discovery, he has been termed 'the father of morphological science.' That O., and not Gütthe, was the original discoverer of the vertebral relations of the skull, has been conclusively shewn by Owen, in a valuable notice of O. in the *Encyclopædia Britannica*.

OKHOTSK, SEA OF, an extensive inlet of the North Pacific Ocean, on the east coast of Russian Siberia. It is bounded on the N. by the wastes of Siberia, on the E. by the peninsula of Kamchatka, and is partially enclosed by the Kurile Islands on the S., and by the island of Saghalien on the W. It is 1000 miles in length, and 500 miles in breadth. The river Ud, which enters it on the north, is 400 miles in length. Owing to climate and position, the Sea of O. is unlikely ever to become the scene of much commerce. On its northern shore, at the mouth of the Okhota—from which it derives its name—is the small seaport of Okhotak, lat. 57° 21' N., long. 143° 17' E. This town has only 236 inhabitants, and has been entirely superseded by the ports of Nikolaevsk and Vladivostok.

OLAF, the Saint, one of the most revered of the early Norwegian kings, was born in 995; and after

having distinguished himself by his gallant exploits, and made his name a terror in several warlike expeditions on the coasts of Normandy and England, succeeded, in 1015, in wresting the throne of Norway from Eric and Svend Jarl. The cruel severity with which he endeavoured to exterminate paganism by fire and sword, alienated the affection of his subjects, many of whom sought security from his persecution in the territories of Knut or Canute the Great, king of Denmark; and it was only through the powerful aid of his brother-in-law, the Swedish Anund Jacob, that his authority could be upheld. O.'s hot-headed zeal, however, after a time exhausted the patience of the people, who hastened to tender their allegiance to Knut, on his landing in Norway in 1023, when O. fled to the court of his brother-in-law, Jaroslav of Russia, who gave him a band of 4000 men, at the head of whom he returned, in 1030, and gave Knut battle at Stiklestad, where O. was defeated by the aid of his own subjects, and slain. The body of the king, which had been left on the field of battle, and buried on the spot by a peasant, having begun to work miracles, his remains were carefully removed to the cathedral of Trondhjem, where the fame of their miraculous power spread far and wide, attracting pilgrims from all parts of the Scandinavian peninsula. O. was solemnly proclaimed patron saint of Norway, in the succeeding century; and from that period till the Reformation, he continued to gather round him a rich heritage of mythical legends and popular sagas, the memory of which still lingers in the folk-lore of Norway. In 1847, the order of Olaf was created, in honour of the Saint, by King Oscar I. of Sweden and Norway.

OLBERS, HEINRICH WILHELM MATHIAS, a celebrated German physician and astronomer, was born at Arbergen, a small village of Bremen, October 11, 1758. He studied medicine at Göttingen from 1777 till 1780, and subsequently commenced to practise at Bremen, where, both as a physician and as a man, he was highly esteemed by his fellow-citizens. In 1811, he was a successful competitor for the prize proposed by Napoleon for the best 'Memoir on the Croup.' O. wrote little on medical subjects, for, from 1779, all the leisure time which he could abstract from professional occupations was devoted to the enthusiastic study of astronomy. The first thing which brought him into notice, was his calculation of the orbit of the comet of 1779, which was performed by him while watching by the bedside of a sick patient, and was found to be very accurate. Comets were the chief objects of his investigation, and he seems to have been seized with an irresistible predilection for these vagabonds of the solar system, which his two important discoveries of the planets Pallas (1802) and Vesta (1807) could not diminish. In 1781, he had the honour of first re-discovering the planet Uranus, which had previously been supposed, even by Herschel himself, to be a comet, and which had been sought for in vain. He also discovered five comets, in 1798, 1802, 1804, 1815, and 1821, all of which, with the exception of that of 1815 (hence called *Olbers' comet*), had been some days previously observed at Paris. His observations, calculations, and notices of various comets, which are of inestimable value to astronomers, were published in the *Annuaire of Bode* (1782—1829), in the *Annuaire of Encke* (1833), and in three collections by the Baron de Zach. Most of these calculations were made after a new method, discovered by himself, for determining the orbit of a comet from three observations; a method which, for facility and accuracy, he considered as greatly preferable to those then in use. A detail of it appeared in a journal published at Weimar (1797), and a new edition by Encke in 1847. O. was one of that small band of astronomers

which included also Schröter, Gauss, Piazzi, Bode, Harding, &c., who in the first ten years of the 19th c. devoted their energies to the observation of those planets which were coming to light between Mars and Jupiter. As above stated, two of them, the second and fourth in order of discovery, were detected by O. himself; and the general equality of the elements of the four planetoids, led him to propound the well-known theory, that these, and the other planetoids (q. v.) since discovered, are but fragments of some large planet which formerly revolved round the sun at a distance equal to the mean of the distances of the planetoids from the same luminary. It was this theory which led him, after the discovery of Pallas, to seek for more fragments of the supposed planet, a search resulting in the discovery of Vesta. O. also made some important researches on the probable lunar origin of meteoric stones, and invented a method for calculating the velocity of falling stars. O. died at Bremen, 2d March 1840; and in 1850, his fellow-citizens erected a marble statue in honour of him. O., as a writer, possessed great powers of thought, combined with equal clearness and elegance of expression. His valuable dissertations are scattered through various journals.

OLD CATHOLICS. See DÖLLINGER and FRIEDRICH, both in SUPP., Vol. X.

OLD POINT COMFORT, a village and watering-place in Virginia, U. S., at the entrance of Hampton Roads, and James River, 12 miles from Norfolk, and the site of Fortress Monroe, the largest military work in the United States.

OLD RED SANDSTONE, the name given to a large series of Palaeozoic rocks, of which red sandstones are the most conspicuous portions, but which contains also white, yellow, or green sandstones, as well as beds of clay and limestone. The group lies below the Carboniferous strata, and was called 'Old' to distinguish it from a newer series of similar beds which occur above the Coal Measures. The discovery that the highly fossiliferous calcareous rocks of Devonshire and the continent occupied the same geological horizon, shewed that the name was very far from being descriptive of all the deposits of the period, and suggested to Murchison and Sedgwick the desirableness of giving them a new designation. They consequently proposed Devonian, which has been extensively adopted; but it is liable to the same objection as that urged against the name it was intended to supplant, inasmuch as it incorrectly limits geographically what the other limits lithologically. Many names used by geologists are similarly at fault; there is therefore no good reason why the old name should be given up, especially as it has been rendered classical by the labours and writings of Hugh Miller, the original monographer of these rocks.

The position of the O. R. S. series is easily determined, though the sequence of the various beds which form it is somewhat obscure. All the rocks are situated between the beds of the Silurian and Carboniferous periods. In Wales, Scotland, and Ireland it has been observed that there is an old series of red sandstones which are more or less conformable with the underlying Silurians, and a newer series unconformable with the older strata, but conformable with the overlying Carboniferous rocks. The great interval represented by this break has been believed to be that during which the Calcareous Devonian rocks were deposited. The recent researches, however, of Mr Salter shew that the one set of beds do not alternate with the other, but that they are really contemporaneous—the coarse shallow water deposits of conglomerate and

sandstone having been formed on the shores of that sea in whose depths the deposits of thicker mass, finer grain, and lighter colour, full of marine shells and corals, were at the same time being aggregated.

The strata of the period have been arranged in four groups. 1. Upper Old Red Sandstone, including the Marwood and Petherwin groups. 2. Middle Old Red Sandstone, including the Dartmouth and Plymouth groups. 3. Lower Old Red Sandstone, including the North Foreland and Torbay groups. 4. Tilestones or Ledbury Shales.

1. The Upper Old Red Sandstones are conformable with the inferior strata of the Coal Measures, and differ so little petrologically, or even palaeontologically from them, that they have been considered as the basement series of that period. They consist of yellowish and light-coloured sandstones, which are at Dura Den, in Fifeshire, remarkably rich in some of their layers in the remains of *Holoptychius*, *Pterichthys*, *Dendrodon*, &c. In the south of Ireland, and at Dunse, similar beds contain a fresh-water shell very like the modern *Anodon*, and fragments of a fern called *Cyclopteris Hibernicus*. Mr Salter has shewn, from the intercalation of the marine beds with the red sandstone, and from the identity of the fossils, that the Devonian representatives of these beds are the Marwood and Petherwin groups. These consist of dark-coloured calcareous and argillaceous beds, and gray and reddish sandstones. The fossils found in them are shells and land-plants, many of them belonging to the same genera, but different species to those which are found in the Carboniferous system. The little crustacean *Cypridina* and *Clymenia* are so characteristic of this division, that in Germany the strata are known as the *Cypridinien Schiefer* and *Clymenien Kalk*.

2. The Middle Old Red Sandstone is represented in the north of Scotland by the Caithness flags, a series of dark-gray bituminous schists, slightly micaceous or calcareous, and remarkably tough and durable. Throughout their whole thickness they are charged with fossil fish and obscure vegetable remains. The characteristic fishes belong to the genera *Coccosteus*, *Asterolepis*, and *Dipterus*. The corresponding beds in Devonshire are the Dartmouth and Plymouth groups, which consist of extensive deposits of limestones and schists, all of them abounding in the remains of corals, trilobites, and shells. In the German equivalent, the Eifel Limestone, but especially in the Russian, the characteristic invertebrate fossils of the Devonshire calcareous beds have been found associated with the remains of *Coccosteus*, shewing beyond doubt the identity of these various beds. The *Calceola Schiefer* of German geologists belongs to the Middle Old Red; it receives its name from the abundance in it of a singular brachiopod (*Calceola sandalina*).

3. The Lower Old Red Sandstone consists of strata of red shale and sandstone, with beds of impure arenaceous limestone (cornstone), and frequently at the base great deposits of red conglomerate. The fossils peculiar to this division are the remarkable fish *Cephalaspis*, and the huge crustacea of the genus *Pterygotus*, besides a few shells. To the south of the Grampians, the strata consist of a gray paving-stone and coarse roofing-slate. The Devonian representatives of this section are the sandstones and slates of the North Foreland, Linton, and Torbay, and the series of slaty beds and quartz ore sandstones developed on the banks of the Rhine near Coblenz. The *Cephalaspis*, so characteristic of the cornstones, has been found in the Rhenish beds.

4. The Tilestones or Ledbury Shales consist of finely laminated reddish and green micaceous

sandstones, which have been noticed underlying the Old Red only on its western borders in Herefordshire. The fossils of these beds shew a Silurian fauna with a number of Old Red forms; the Tilestones are consequently referred sometimes to the one period, and sometimes to the other.

The O. R. S. occupies a considerable portion of the surface of Great Britain. In the north, it forms the boundary lands of the Moray Firth; beginning even as far north as the Shetlands and Orkneys, it covers the whole of Caithness, and in more or less broken tracts the east of Sutherland, Ross, and Cromarty, and the north of Inverness, Nairn, and Elgin. In the great central valley of Scotland it is the setting in which the coal measures are placed, stretching across the country on the one margin from Forfar to Dumbarton, and occurring on the other in separated tracts in Lanark and Berwick. In the southern division of the island it is limited to a large triangular district in the south-west. The apex of the triangle is at Wenlock, in Shropshire; a line thence to Start Point, in Devon, would limit it on the east, and a second to Milford Haven would do so on the west. The Bristol Channel bisects it. A depression in the Welsh portion is occupied with South Wales coal-field; and in a similar depression in Devon, the culm-beds are situated. In Ireland, strata of this age are found in the counties of Kilkenny, Waterford, Cork, and Kerry. The Devonian rocks have been carefully studied in Belgium and the Rhine district, and also in Russia, where they cover a larger district in the north of the empire. The American representatives of this period are extensively developed in New York, Pennsylvania, and Canada. The invertebrate animals found in the Old Red do not differ much from those of the Upper Silurian. Corals are remarkably abundant and beautiful in the Devonian limestones. *Goniatites* and *Clymenia* make their first appearance in this period, with several forms of lower mollusca. Trilobites are still numerous. But the most striking feature in the period is the abundance of fish of curious forms, strongly protected outside by hard bony cases, or by a dense armour of ganoid scales.

OLDBURY, an important manufacturing town of England, in the county of Worcester, 29 miles north-north-east of the city of that name, on the river Tame. It contains numerous churches, meeting-houses, and schools. Owing to the extension of the iron-trade, O. has greatly increased in size and prosperity within recent years. There are coal and iron mines in the neighbourhood; and in the town, iron, steel, locomotive engines, mills, edge-tools, draining-pipes, &c., are made and constructed. The Stour Valley Railway passes close by the town, and there is a station here. Pop. (1871) 16,410; (1881) 18,821.

OLDCASTLE, SIR JOHN, once popularly known as the 'good Lord Cobham,' whose claim to distinction is, that he was the first author and the first martyr among the English nobility, was born in the reign of Edward III.; the exact year is not known. He acquired the title of Lord Cobham by marriage, and signalled himself by the ardour of his attachment to the doctrines of Wickliffe. At that time, there was a party among the English nobles and gentry sincerely, and even strongly desirous of ecclesiastical reform—the leader of which was 'old John of Gaunt—time-honoured Lancaster.' O. was active in the same cause, and took part in the presentation of a remonstrance to the English Commons on the subject of the corruptions of the church. At his own expense, he got the works of Wickliffe transcribed, and widely disseminated among the people, and paid a large body

of preachers to propagate the views of the reformer throughout the country. During the reign of Henry IV., he commanded an English army in France, and forced the Duke of Orleans to raise the siege of Paris; but in the reign of Henry V. he was accused of heresy, and having, in a disputation with his sovereign, declared that 'as sure as God's word is true, the pope is the great Antichrist foretold in Holy Writ,' he was thrown into the Tower, whence, after some time, he escaped, and concealed himself in Wales. A bill of attainder was passed against him, and 1000 marks set upon his head. After four years' hiding, he was captured, brought to London, and—being reckoned a traitor as well as a heretic—he was hung up in chains alive upon a gallows, and fire being put under him, was burned to death, December 1417. O. wrote *Twelve Conclusions addressed to the Parliament of England*, several monkish rhymes against 'fleshly livers' among the clergy, religious discourses, &c. Halliwell proved that Shakspeare's Sir John Falstaff was originally Sir John O.

OLDENBURG, a grand-duchy of Northern Germany, consisting of three distinct and widely separated territories, viz., Oldenburg Proper, the principality of Lübeck, and the principality of Birkenfeld. Total area, 2461 sq. m.; pop. (1880) 337,478. Oldenburg Proper which comprises $\frac{1}{3}$ ths of this area, and $\frac{1}{3}$ ths of the entire population, is bounded on the N. by the German Ocean, on the E., S., and W. by the kingdom of Hanover. The principal rivers of O. are the Weser, the Jahde, and the Haase, Vehn, and other tributaries of the Ems. The grand-duchy of Oldenburg Proper is divided into eight circles. The country is flat, belonging to the great sandy plain of Northern Germany, and consists for the most part of moors, heaths, marsh or fens, and uncultivated sandy tracts; but here and there, on the banks of the rivers, the uniform level is broken by gentle acclivities, covered with wood, or by picturesque lakes surrounded by fruitful pasture-lands. Agriculture and the rearing of cattle constitute the chief sources of wealth. The horses and cattle raised in the marsh-lands are excellent of their kind, and in great request; the horse-markets at Oldenburg, and the cattle-sales at Ovelgönne, being frequented by purchasers from every part of Germany. The scarcity of wood for fuel, and the absence of coal, are compensated for by the existence of turf-beds of enormous extent. With the exception of some linen and stocking looms, and a few tobacco-works, there are no manufactories. There are, however, numerous distilleries, breweries, and tan-yards in all parts of the duchy.

The trade is principally a coasting-trade, carried on in small vessels, from 20 to 40 tons, which can thread their way along the shallow channels connecting the larger rivers.

The exports are horses, cattle, linens, thread, hides, and rags, which find their way chiefly to Holland and the Hanseatic cities; while the imports include the ordinary colonial goods, and manufactures of numerous kinds.

The receipts for the collective grand-duchy were in the budget for 1881, £360,540, and the expenditure, £380,774. The public debt, at the close of 1880, was £1,840,565.

The principality of Lübeck, consisting of the secularised territories of the former bishopric of the same name, is surrounded by the duchy of Holstein, and is situated on the banks of the rivers Schwartau and Trave. It contributes 199 square miles to the general area of the grand-duchy, and 34,961 inhabitants to the collective population. It is divided into four administrative districts. It has several large lakes, as those of Plön—noted for

OLDENBURG.

its picturesque beauty—Keller, Uklei, and Gross-Eutin; while in regard to climate, soil, and natural products, it participates in the general physical characteristics of Holstein. The chief town is Eutin (pop., in 1881, 3700), pleasantly situated on the lake of the same name, with a fine castle surrounded by a magnificent park.

The principality of Birkenfeld, lying south-west of the Rhine, among the Hunsrück Mountains, and between Rhenish Prussia and Lichtenberg, is an outlying territory, situated in lat. $49^{\circ} 30' - 49^{\circ} 52' N.$, and in long. $7^{\circ} - 7^{\circ} 30' E.$ Its area is 192 square miles, and its pop. 37,093. The soil of Birkenfeld is not generally productive; but in the lower and more sheltered valleys, it yields wheat, flax, and hemp. Wood is abundant. The mineral products, which are of considerable importance, comprise iron, copper, lead, coal, and building-stone; while in addition to the rearing of cattle, sheep, and swine, the polishing of stones, more especially agates, constitutes the principal source of industry. The principality is divided into three governmental districts.

O. is a constitutional ducal monarchy, hereditary in the male line of the reigning family. The constitution, which is based upon that of 1849, revised in 1852, is common to the three provinces, which are represented in one joint chamber, composed of 33 members, chosen by free voters. Each principality has, however, its special provincial council, the members of which are likewise elected by votes; while each governmental district within the provinces has its local board of councillors, and its several courts of law, police, finance, &c.; although the highest judicial court of appeal, and the ecclesiastical and ministerial offices, are located at Oldenburg.

Perfect liberty of conscience was guaranteed by the constitution of 1849. The Lutheran is the predominant church, upwards of 200,000 of the population belonging to that denomination; while about 70,000 persons profess the Roman Catholic religion.

There are two gymnasia, one higher provincial college, several secondary, and 500 elementary schools; but in consequence of the scarcity of villages in the duchy, and the isolated position of many of the houses of the peasantry, schools are not common in the country districts, and the standard of education of the lower classes is, from these causes, scarcely equal to that existing in other parts of Northern Germany. The military forces of O.—above 2000 men on the peace footing—form a portion of the Prussian army. The merchant navy consists of about 350 vessels of some 70,000 tons. O. is represented in the Bundesrath or Federal Council of the German Empire by 1 member, and in the Reichstag or Diet by 3 members.

History.—The territory now included in the grand-duchy of O., was in ancient times occupied by the Teutonic race of the Chauci, who were subsequently merged with the more generally known Frisii, or Frisians; and the land, under the names of Ammergau and Lerigan, was for a long period included among the dominions of the Dukes of Saxony. In 1180, the Counts of O. and Delmenhorst succeeded in establishing independent states from the territories of Henry the Lion, which fell into a condition of disorganisation after his downfall.

This family has continued to rule O. to the present day, giving, moreover, new dynasties to the kingdom of Denmark, the empire of Russia, and the kingdom of Sweden. See OLDENBURG, HOUSE OF. On the death, in 1667, of Count Anthony Gunther, the wisest and best of the O. rulers, his dominions, in default of nearer heirs, fell to the

Danish reigning family, and continued for a century to be ruled by viceroys nominated by the kings of Denmark. This union was, however, severed in 1773, when, by a family compact, Christian VII. made over his O. territories to the Grand Duke Paul of Russia, who represented the Holstein-Gottorp branch of the family. Paul having renounced the joint countships of Delmenhorst and O. in favour of his cousin, Frederick Augustus, of the younger or Kiel line, of the House of O., who was Prince-bishop of Lübeck, the emperor raised the united O. territories to the rank of a duchy. The present reigning family is descended from Duke Peter Friedrich Ludwig, cousin to the Prince-bishop, Frederick Augustus. For a time, the duke was a member of Napoleon's Rhenish Confederation; but French troops having, in spite of this bond of alliance, taken forcible possession of the duchy in 1811, and incorporated it with the French empire, the ejected prince joined the ranks of the allies. In recognition of this adhesion, the Congress of Vienna transferred certain portions of territory, with 5000 Hanoverians and 20,000 inhabitants of the quondam French district of the Saar, to the O. allegiance. From these new acquisitions were organised the district Amme, and the principality of Birkenfeld; while O. was raised to the dignity of a grand-duchy. The revolutionary movement of 1848 was quite as productive of violent and compulsory political changes in this as in other German states; and in 1849, after having existed for centuries without even a show of constitutional or legislative freedom, it entered suddenly into possession of the most extreme of liberal constitutions. The reaction in favour of absolutism, which the licence and want of purpose of the popular party naturally induced all over Germany, led in 1852 to a revision and modification of the constitution, which, however, in its present form contains the essential principles of popular liberty and security, though it must be confessed this is more verbal than real. In the German-Italian war, O. sided with Prussia, and afterwards joined the North German Confederation. The duchy concluded, in 1866, a treaty with Prussia, by which the Grand-Duke renounced his claims to the Holstein succession, for the cession to him of a small portion of Holstein territory, and an indemnity of 1,000,000 thalers. O. is now included in the German Empire.

OLDENBURG, capital of the grand-duchy of the same name, is pleasantly situated on the banks of the navigable river Hunte, 25 miles west-north-west of Bremen. Pop. (1880) 18,416. O. is the seat of the administrative departments, and the focus of the literary, scientific, and commercial activity of the duchy. It has a normal school, a military academy, a public library of 85,000 vols., a picture-gallery, museum, &c. The grand-ducal palace is worthy of note for its fine gardens, its valuable pictures, and other art collections, and its library. The principal church is St Lambert's, containing the burying-vaults of the reigning family. O. is the seat of an active river-trade, and is noted for its excellent studs, and the great cattle and horse fairs which are annually held here in the months of June and August.

OLDENBURG, THE HOUSE OF, which lays just claim to being one of the oldest reigning families of Europe, has been rendered still more illustrious by various matrimonial alliances, which, in the course of ages, have successively been the means of creating new royal dynasties. Thus, for instance, in 1448, a scion of this House being elected king of Denmark, under the title of Christian I., became the progenitor of the Danish House of Oldenburg, the imperial

House of Russia, the late royal family of Sweden, and the collateral and junior Danish lines of Angustenburg, Kiel, and Sonderburg-Glücksburg. Christian owed his election to the recommendation of his maternal uncle, Duke Adolph of Slesvig, who, when the throne was offered to him on the sudden death of King Christopher, refused, on the ground of age, and proposed Christian of Oldenburg, who, as the direct descendant of Eric Glipping's daughter, Princess Richissa, was allied to the old extinct House of Denmark. The death, in 1459, of Adolph, Duke of Slesvig and Count of Holstein, without male heirs, opened the question of succession to those states, which has since become one of such vexatious import. The ancient law of Denmark recognised hereditary fiefs only in exceptional cases; crown fiefs being generally held for life or merely for a time *ad gratiam*. Such being the case, Slesvig might, on the death of Adolph, have been taken by the crown as a lapsed tenure; but Holstein, being held under the empire, would have been separated from it. Adolph and his subjects were alike anxious that Slesvig and Holstein should continue united; but although the Slesvig estates, at the wish of the Duke Adolph, had recognised Christian as successor to the duchy before his accession to the throne of Denmark, the Holstein Chambers were divided on the question of succession, the majority shewing a preference for the claims of the counts of Schauenburg, who were descended from male agnates of the Holstein House. Christian, in his eagerness to secure both states, was willing to sacrifice his rights in Slesvig to his schemes in regard to Holstein; and having bought over the Holstein nobles by bribes and fair promises, he was elected Duke of Slesvig and Count of Holstein at Ribe in 1460, where he signed a deed, alike derogatory to the interests and unworthy the dignity of his crown. In this compact, by which he bartered away the just prerogatives and independence of himself and his successors, for the sake of nominal present gain, he pledged his word for himself and his heirs, that the two provinces should always remain undivided, '*ewig bliben tosamende ungedeelt*,' and not be dismembered by division or heritage. This document, which remained for ages unknown or forgotten, was discovered by the historian Dahlmann amid the neglected papers of the Holstein state archives at Preetz, and proclaimed in 1848 by that ardent admirer of Germany as the unchangeable fundamental law of the Slesvig-Holstein provinces. The confusion, dissension, and ill-will to which this fatal deed has given rise, are the fruits which Christian's unscrupulous desire to secure power at any cost has produced for his descendants, whose complicated claims on the duchies resulted, in 1864, in a war which cost Denmark a large portion of her territorial possession. From Christian I. descend two distinct branches of the Oldenburg line: 1. The royal dynasty, extinct in the male line in Frederick VII., late king of Denmark, and the collateral branches of Sonderburg-Augustenburg, and Sonderburg-Glücksburg; 2. The ducal Holstein-Gottorp line, descended from Duke Adolph, who died in 1586, and was the second son of King Frederick I. This prince had received, during his father's lifetime, a portion of the Slesvig and Holstein lands, which he was permitted, on the accession of his elder brother, Christian III., to retain for himself and his heirs. This line became illustrious by the marriage of Prince Karl Friedrich, the son of Hedwig-Sofia, eldest sister of Charles XII. of Sweden (a direct descendant of Duke Adolph) with the Grand-duchess Anna, daughter of Peter the Great, and thus gave to Russia the dynasty which still occupies the imperial throne; while Adolph-Friedrich,

a cousin of Prince Karl Friedrich, by his election to the throne of Sweden in 1751, added another crown to those already held by the House of Oldenburg. The conduct of his descendants rendered the new dignity short-lived, for with the abdication of Gustavus IV., in 1809, the Holstein-Gottorp dynasty became extinct in Sweden.

The complicated relations of the House of O. in regard to the Danish succession, after giving rise to much angry discussion among the princes interested in the question, and the Danish people themselves, led the great powers to enter into a treaty, known as the London Treaty of 1852, for settling the question of succession, on the ground that the integrity of the Danish monarchy was intimately connected with the maintenance of the balance of power and the cause of peace in Europe. England, France, Austria, Prussia, Russia, Sweden, and Denmark, were parties to this treaty, in the first article of which it was provided, that on the extinction of the male line of the royal House, Prince Christian of Slesvig-Holstein-Sonderburg-Glücksburg, and his male heirs, according to the order of primogeniture, should succeed to all the dominions, then united under the sway of the king of Denmark. The rights of succession, which rested with the Augustenburg family, were forfeited by a compact which the Duke of Augustenburg entered into for the surrender of his claims, in consideration of a sum of money paid to him by Denmark. The duke's morganatic marriage, and his subsequent rebellion, in 1848, against the Danish king, were the causes which led to the arrangement of this family compact on the existing terms. This treaty, known as the London Protocol of May 1852, was followed in October of the same year by the publication of a supplementary clause, which stipulated, that on the extinction of the heirs-male of Prince Christian of Slesvig-Holstein-Sonderburg-Glücksburg, the Holstein-Gottorp, or imperial Russian line should succeed to the Danish dominions. This article, even more than the original clauses of the treaty, met with the strongest opposition among the Danes, and after being twice rejected in the Landthing, the London Treaty was only ratified after a new election of members, and on the assurance of the king that in excluding all female cognate lines from the succession, there was no definite intention of advancing the claims of Russia. King Frederick's death, in 1863, brought on the crisis of the much-vexed question of the Danish succession; and although the London Treaty was so far followed that Prince Christian succeeded as king of Denmark, the evils that were anticipated from the measure were in 1864 made painfully manifest; for the Duke of Augustenburg, notwithstanding the renunciation by his family of all claims to the succession, appealed to the federal diet for the recognition of his rights on Holstein; and the German powers, glad of a pretext to extend their influence beyond the Eider, occupied the Slesvig-Holstein (q. v.) territory, and succeeded, by force of superior numbers, in advancing the boundary of Germany to the borders of Jutland. This led, however, to grave results affecting the whole of Europe. Prussia and Austria took possession of the conquests in their own names. The former power offered the latter pecuniary compensation for their assistance in the war, while indicating a determination to annex the duchies to its own dominions. Austria refused, and this led to the disastrous battle of Königgratz.

O'LDHAM, a parliamentary borough and flourishing manufacturing town of England, in the county of Lancashire, stands on the Medlock, six miles north-east of Manchester. It owes its rapid increase in population and in wealth to the

extensive coal-mines in the vicinity, and to its cotton manufactures, which have increased remarkably within late years. It is not only the great centre of the hat-manufacture, but is also celebrated for its manufactures of fustians, velveteens, cords, cotton, woollen, and silk goods. Numerous silk-mills, brass and iron foundries, machine-shops, tanneries, rope-works, &c., are in operation. The parish church, the town-hall, the Blue-coat and the Grammar-schools, are the chief edifices. Pop. of municipal borough, (1871) 82,629, (1881) 111,343; of parliamentary borough (which returns two members to parliament), (1871) 113,100, (1881) 152,511.

OLDHAMIA, a genus of fossil zoophytes, dedicated by Forbes to Professor Oldham, who was their discoverer. Only two species are known, but they are of peculiar interest, because, with their associated worm-tracks and burrows, they are the first distinct evidence of life on the globe. They exist as mere tracings on the surface of the laminae of metamorphosed shales, all remains of the substance of the organism having entirely disappeared. The form of the hard polypidom is preserved, and shews a jointed main stem, giving off at each joint, in the one species, a circle of simple rays, and in the other a fan-shaped group. Forbes pointed out their affinities in some respects to the Hydrozoa, and in others to the Polyzoa. Kinahan, who described the genus at some length, considers them to have been Hydrozoa allied to Sertularia; while Huxley places them among the Polyzoa.

OLDYS, WILLIAM, a most erudite and industrious bibliographer, was a natural son of Dr William Oldys, Chancellor of Lincoln, and advocate of the Admiralty Court, and was born in 1687. Regarding his early life, little is known. His father dying in 1708, left him a small property, which O. squandered as soon as he got it into his own hands. The most of his life was spent as a bookseller's hack. He drank hard; and was so scandalously fond of low company, that he preferred to live within the 'rules' of the Fleet Prison to any more respectable place. As may easily be supposed from his habits, the dissolute old bookworm was often in extremely necessitous circumstances, and when he died (April 15, 1761), he left hardly enough to decently bury him. It is but fair to add that O. had some sterling merits. Captain Grose, who knew him, praises his good-nature, honour, and integrity as a historian, and says that 'nothing would ever have biassed him to insert any fact in his writings which he did not believe, or to suppress any he did.' For about ten years, O. acted as librarian to the Earl of Oxford, whose valuable collection of books and MSS. he arranged and catalogued. His chief works are *The British Librarian, exhibiting a Compendious Review of all Unpublished and Valuable Books in all Sciences* (London, 1737, anonymously); a *Life of Sir Walter Raleigh*, prefixed to Raleigh's *History of the World* (1738); a translation of Camden's *Britannia* (2 vols.); *The Harleian Miscellany, or a Collection of Source, Curious, and Entertaining Tracts* (8 vols. Lond. 1753). Besides these, O. wrote a great variety of miscellaneous literary and bibliographical 'articles' for his friends the booksellers, which it would be tedious to mention.

OLEACEÆ, a natural order of exogenous plants, consisting of trees and shrubs, with opposite leaves, and flowers in racemes or panicles. The calyx is in one piece, divided, persistent; the corolla is hypogynous, generally 4-cleft, sometimes of four petals, sometimes wanting; there are generally two, rarely four stamens; the ovary is free, 2-celled, the cells 2-seeded; the fruit is a drupe, a capsule, or a samara (see these heads); the cotyledons are

foliaceous. Nearly 150 species are known, mostly natives of temperate countries. Among them are the olive, ash, lilac, privet, phillyrea, fringe tree, &c. Between some of these there is a great dissimilarity, so that this order is apt to be regarded as a very heterogeneous group; but the real affinity of the species composing it is manifested by the fact, that even those which seem most unlike can be grafted one upon another, as the lilac or the olive on the ash. Bitter, astringent, and tonic properties are prevalent in this order.

OLEANDER (*Nerium*), a genus of plants of the natural order *Apocynaceæ*, having a 5-parted calyx, set round on the inside at the base with many tooth-like points or glands, a salver-shaped 5-cleft corolla, in the throat of which is a 5-parted and toothed or lacerated corona, five stamens, the anthers adhering to the stigma, the fruit composed of two follicles. The species are evergreen shrubs with leathery leaves, which are opposite or in threes; the flowers in false umbels, terminal or axillary. The COMMON O. (*N. oleander*), a native of the south of Europe, the north of Africa, and many of the warmer temperate parts of Asia, is frequently planted in many countries as an ornamental shrub, and is not uncommon in Britain as a window-plant. It has beautiful red, or sometimes white, flowers. The English call it ROSE BAY, and the French ROSE LAUREL (*Laurier Rose*). It attains a height of eight or ten feet. Its flowers give a splendid appearance to many ruins in the south of Italy. It delights in moist situations, and is often found near streams. All parts of it contain a bitter and narcotic-acrid juice, poisonous to men and cattle, which flows out as a white milk when young twigs are broken off. Cases of poisoning have occurred by children eating its flowers, and even by the use of the wood for spits or skewers in roasting meat. Its exhalations are injurious to those who remain long under their influence, particularly to those who sleep under it. A decoction of the leaves or bark is much used in the south of France as a wash to cure cutaneous maladies.—*N. odoratum*, an Indian species, has larger flowers, which are very fragrant.—*N. piscidium* (or *Eschaltum piscidium*), a perennial climber, a native of the Kasya Hills, has a very fibrous bark, the fibre of which is used in India as hemp. The steeping of the stems in ponds kills fish.

OLEASTER. See **ELÆAGNUS**.

OLEFIANT GAS (C_4H_4) is transparent and colourless, possesses a disagreeable alliaceous odour, and acts as a poison when breathed. Its specific gravity is 0.981. It takes fire when brought in contact with a flame, and burns with a bright clear light. When this gas is mixed with oxygen or atmospheric air in the proportion of 1 volume with 3 volumes of oxygen, or with 15 volumes of atmospheric air, it forms a powerfully explosive mixture. It is more soluble in cold than in hot water—100 volumes of water at 32° absorbing 26.5 volumes of the gas, while at 68° they only absorb 14 volumes. It was liquefied by Faraday, under great pressure, but remained unfrozen at -166°. If it be conducted through strongly-heated tubes, or if a continuous series of electric sparks be passed through it, it is decomposed into a very dense black carbon, and double its own volume of hydrogen; and if it is subjected to a less intense heat, the products of decomposition are carbon and light carburetted hydrogen or marsh gas (C_2H_4). Chlorine acts upon this gas in a very remarkable manner. When the two gases are mixed in equal volumes, they combine to form a heavy oily liquid, to which the term chloride of olefant gas, or Dutch Liquid (q. v.), is

given. Olefant gas is a constituent of the gaseous explosive admixtures that accumulate in coal-pits, and of the gaseous products yielded by the distillation of wood, resinous matters, and coal; and the brightness of the flame of ordinary gas depends partly on the quantity of olefant gas present. This gas is most readily obtained by the action of sulphuric acid on alcohol.

O'LEIC ACID, at temperatures above 57°, exists as a colourless limpid fluid, of an oily consistence, devoid of smell and taste, and (if it has not been exposed to air) exerting no action on vegetable colours. At 40°, it solidifies into a firm, white, crystalline mass, and in this state it undergoes no change in the air; but when fluid, it readily absorbs oxygen, becomes yellow and rancid, and exhibits a strong acid reaction with litmus paper. It is not a volatile acid, and on the application of a strong heat, it breaks up into several substances, such as caproic, caprylic, and sebacic acids. If oleic acid be exposed to the action of hyponitric acid, it is converted into an isomeric, solid, fatty acid, termed *elaidic acid*. When distilled with moderately strong nitric acid, it is oxidised into a large number of products, including all the volatile fatty acids, from formic acid to capric acid. When heated with hydrated potash, it breaks up into palmitic and acetic acids. It is very difficult to obtain the acid in a state of purity, in consequence of the readiness with which it oxidises. It is obtained in a crude form, as a secondary product, in the manufacture of stearine candles; but almond oil is generally employed when the pure acid is required. Oleic acid forms normal (or neutral) and acid salts; but the only compounds of this class that require notice are the normal salts of the alkalies. These are all soluble, and by the evaporation of their aqueous solution, form *soaps*. Oleate of potash forms a soft soap, which is the chief ingredient in Naples soap; while oleate of soda is a hard soap, which enters largely into the composition of Marseille soap. The oleates of the alkalies occur in the animal body, in the blood, chyle, lymph, and bile; they have also been found in pus, in pulmonary tubercles, and in the excrements, after the administration of purgatives.

O'LEINE is proved, by the researches of Berthelot, to be a triglyceride of oleic acid. See GLYCERINE. Pure oleine is a colourless and inodorous oil, which solidifies into acicular crystals at about 23°, is insoluble in water, and only slightly soluble in cold alcohol, but dissolves in ether in all proportions. By exposure to the air, it darkens in colour, becomes acid and rancid (from the gradual decomposition of the oleic acid), and finally assumes a resinoid appearance. Hyponitric acid converts it into an isomeric, white, solid fat, named *elaidine*—the glyceride of elaidic acid. Pure oleine is obtained by cooling olive oil to 32°, which occasions the separation of the stearine and palmitine in a solid form. The fluid portion is then dissolved in alcohol, which, on being cooled to 32°, deposits in a solid form everything but oleine, which is obtained in a pure state by driving off by heat the alcohol from the decanted or filtered solution.

OLEOGRAPH. This is a name given to an ordinary chromo-lithograph which has been 'roughed,' as it is termed, on a lithographic stone engraved so as to imitate canvas. The resemblance to oil paintings which oleographs have when not looked at too closely, is produced partly by this roughing process and partly also by their being mounted on canvas, sized, and varnished. The colours used in printing oleographs, since they are meant to imitate oil pictures, are used a little

darker than in the case of chromo-lithographs in imitation of water-colour drawings.

OLEO-MARGARINE, also called Butterine, is animal grease in disguise, and is the outcome of an ingenious Frenchman's notion that the butter diffused through the milk of the cow is due to the absorption of the animal's fat. Taking some minced beef-suet, a few fresh sheep's stomachs cut into small pieces, carbonate of potash, and water, M. Mège-Mouriez subjected the mixture to a heat of 113° Fahrenheit; and so, by the action of the pepsine in the sheep's stomachs, separated the fat from the other tissues. By hydraulic pressure this fat was again separated into stearine and margarine; and on putting ten pounds of the latter into a churn with four pints of milk, three pints of water, and a little arnotto, and churning the compound, it was easy to turn out a compound sufficiently like butter to pass for that article. The inventor patented his process; and found no difficulty in selling licenses to work it in France, England, Holland, Germany, and America. In America the manufacture of oleo-margarine developed very rapidly. Of numerous factories working the process, the largest, in New York, began in 1876, and was soon converting half-a-million pounds of fat per week into sham butter, or butter-oil. That quantity of fat would produce 200,000 lbs. of oil or butter. In 1880 it was estimated that this one company exported yearly about 3,000,000 lbs. of oleo-margarine, and that other manufacturers exported from New York port alone as much more. Some is brought direct to Great Britain as oil or 'butter'; a large quantity of the oil finds its way to Holland and Germany, is there mixed with a certain proportion of milk, churned, and re-shipped to England as butterine or butter. In the House of Commons in 1881, it was declared by the best authorities that the substances so produced were innocuous, and that good butterine was much more wholesome than bad butter.

OLEOMETER, or ELAIOMETER, an instrument for ascertaining the densities of fixed oils. It consists of a very delicate thermometer-tube, the bulb being large in proportion to the stem. It is divided into fifty degrees, and floats at zero in pure oil of poppy-seed, at 38° to 38½° in pure oil of almonds, and at 50° in pure olive oil.

O'LEOPHOSPHORIC ACID is a yellow viscid substance, which is insoluble in water and cold alcohol, but dissolves readily in boiling alcohol and in ether. When boiled for a long time with water or with alcohol, or when treated with an acid, it resolves itself into oleine and phosphoric acid; while alkalies decompose it into phosphoric acid, oleates, and glycerine.

OLÉRON, ISLE OF (anc. *Uliarus*), an island of France, forming part of the department of Charente-Inférieure, lies off the west coast of France. It is 19 miles long, and about 5 miles broad, and is unusually fertile. Pop. 18,200, mostly Protestants. On O. are the port of Le Chateau, and the small towns of St Pierre d'O. and St George's d'O.

OLÉRON, LAWS OF, or JUGEMENTS D'OLÉRON, a celebrated code of maritime law compiled in France in the reign of St Louis, and so named from a groundless story, that it was enacted by Richard I. of England during the time that his expedition to Palestine lay at anchor at that island. The real origin of these laws was a written code, called *Il Consolato del Mare*, of about the middle of the 13th c., compiled either at Barcelona or at Pisa, forming the established usages of Venice and the other Mediterranean states, and acceded to by the kings of France and counts of Provence. Besides containing regulations simply mercantile, this system

defined the mutual rights of belligerent and neutral vessels, as they have been since understood in modern international law. The so-called laws of Oléron were a code of regulations borrowed from the *Consolato*, which for several centuries were adopted as the basis of their maritime law by all the nations of Europe. Copies of the *Jugements d'Oléron* are appended to some ancient editions of the *Coutumier de Normandie*. See NORMANDY, CUSTOMARY LAW OF.

OLGA, St., a saint of the Russian Church, wife of the Duke Igor of Kiev, who, having undertaken an expedition against Constantinople, which proved unsuccessful, was slain on his return to his own dominions. His widow O. avenged his death, assumed the government in his stead, and for many years governed with much prudence and success. Having resigned the government to her son Vratialaf about the year 952, she repaired to Constantinople, where she was baptized, by the patriarch Theophilaktos, and received into the church, assuming at baptism the name of Helena, in honour of St Helena, mother of Constantine. She returned to Russia, and laboured with much zeal for the propagation of her new creed; but she failed in her attempt to induce her son, Swântoslav, to embrace Christianity. Her grandson, Vladimir, having married Chrysoberga, the sister of the emperors of Constantinople, Basil and Constantine, was baptized in the year 988; but his grandmother did not live to enjoy this gratification, having died in 978, or, according to other authorities, as early as 970. She is held in high veneration in the Russian Church. Her festival is held on July 21, and the practice of venerating her appears to date from the early period of the Russian Church, before the schism between the Eastern and Western churches.

OLIBANUM, a gum-resin, which flows from incisions made in *Bonellia serrata*, a tree found in some parts of the East. See BOSWELLIA. It is the *Lebanah* of the Hebrews, *Libanos* or *Libanotos* of the Greeks, *Thus* of the Romans, of all which terms the ordinary English translation is *Frankincense* (q.v.). It occurs in commerce in semi-transparent yellowish tears and masses; has a bitter nauseous taste; is hard, brittle, and capable of being pulverised; and diffuses a strong aromatic odour when burned. It was formerly used in medicine, chiefly to restrain excessive mucous discharges; but its use for such purposes is now rare. It sometimes enters as an ingredient into stimulating plasters. It is chiefly employed for fumigation, and is used as incense in Roman Catholic churches. It is sometimes distinctively called *Indian O.*; a similar substance, in smaller tears, called *African O.*, being produced by *Bonellia papyrifera*, a tree found growing on bare limestone rocks in the east of Abyssinia, and sending its roots to a great depth into the crevices of the rock. The middle layers of the bark are of fine texture, and are used instead of paper for writing.

OLIFANT'S RIVER. Two considerable streams of this name are found in the Cape Colony. The Olifant's River West rises in the Winterhoek Mountains, and enters the Atlantic in lat. 31° 40', after a course of 150 miles, and a basin of drainage of 25,000 square miles.—The Olifant's River East drains a great part of the district of George, and joins the Gauritz River 60 miles above the entrance of that river into the sea. Its course is upwards of 150 miles in length, and it is more available for irrigation than almost any other Cape river.

O'LIGAROHY (*oligos*, few, and *archo*, to govern), a term applied by Greek political writers to that perversion of an aristocracy in which the rule of the

dominant part of the community ceases to be the exponent of the general interests of the state, owing to the cessation of those substantial grounds of pre-eminence in which an aristocracy originated. The governing power in these circumstances becomes a faction, whose efforts are chiefly devoted to their own aggrandisement and the extension of their power and privileges.

OLINDA, a suburb of Pernambuco (q. v.).

OLIPHANT, MRS MARGARET (*née* WILSON), one of the most distinguished of our living female novelists, was born about the year 1820. The prevalent impression that she is a Scotchwoman, naturally enough derived from the obvious fondness with which in her earlier works she has treated Scottish character and incident, is not strictly correct. She is a native of Liverpool; her mother was, however, a Scotchwoman of a somewhat remarkable type, strongly attached to old traditions. In 1849, Mrs O. published her first work, *Passages in the Life of Mrs Margaret Maitland of Sunnyside*, which instantly won attention and approval. Its most distinctive charm is the tender humour and insight which regulate its exquisite delineation of Scottish life and character at once in their higher and lower levels. This work was followed by *Merkland* (1851); *Adam Graeme of Mossgrey* (1852); *Harry Muir* (1853); *Magdalen Hepburn* (1854); *Lilliesleaf* (1855); and subsequently by *Zaidee*, *Katie Stewart*, and *The Quiet Heart*, which originally appeared in succession in *Blackwood's Magazine*. Though these are of somewhat various merit, in all of them the peculiar talent of the writer is marked. They are rich in the minute detail which is dear to the womanly mind; have nice and subtle insights into character, a flavour of quiet humour, and frequent traits of delicacy and pathos in the treatment of the gentler emotions. It is, however, on the *Chronicles of Carlingford* that her reputation as a novelist was first secured. In the first of the two sections separately published, apart from its other merits, which are great, the character of little Netty, the heroine, vivifies the whole work, and may rank as an original creation. The other, *Salem Chapel*, perhaps indicates a wider and more vigorous grasp than is to be found in any other work of the authoress. Certain of the unlovelier features of English dissent, as exhibited in a small provincial community, are here graphically sketched, and adapted with admirable skill to the purposes of fiction. In 1870, she published *Three Brothers*; in 1871, *Squire Arden*; in 1872, *Ombra*; in 1874, *A Rose in June*; in 1876, *Phoebe Junior*; in 1878, *The Primrose Path*; in 1879, *Within the Precincts*. Also: *Life of Edward Irving*; *St Francis of Assisi*; *Memoir of the Comte de Montalembert*; *The Makers of Florence*; *The Literary History of England*, from 1790 to 1825 (1882); *A Little Pilgrim: in the Unseen* (on Spiritualism); and *Dante and Cervantes* in the series of *Foreign Classics for English Readers*, for which she has also acted as editor.

OLIVAREZ, DON GASPARD DE GUZMAN, COUNT OF, Duke of San Lucar, and prime-minister of Philip IV. of Spain, was born on January 6, 1587, at Rome, where his father was ambassador. He belonged to a distinguished but impoverished family, received a learned education, became the friend of Philip IV., his confidant in his amours, and afterwards his prime-minister, in which capacity he exercised almost unlimited power for twenty-two years. O. shewed ability for government, but his constant endeavour was to wring money from the country that he might carry on wars. His oppressive measures caused insurrections in Catalonia and

Andalusia, and roused the Portuguese to shake off the Spanish yoke in 1640, and make the Duke of Braganza their king, an event which O. reported to Philip with satisfaction, as it enabled him to confiscate the duke's great estates in Spain. But the arms of Spain being unsuccessful, the king was obliged to dismiss the minister in 1643. He would probably have been recalled to the head of affairs, but for a publication in which he gave offence to many persons of influence. He was ordered to retire to Toro, and confine himself to that place, where he died, 12th July 1645. (Cespedes, *Hist. De Felipe IV.*)

OLIVE (*Olea*), a genus of trees and shrubs of the natural order *Oleaceæ*; having opposite, ever-green, leathery leaves, which are generally entire, smooth, and minutely scaly; small flowers in compound axillary racemes, or in thyrsi at the end of the twigs; a small 4-toothed calyx, a 4-cleft corolla, two stamens, a 2-cleft stigma; the fruit a drupe. The species are widely distributed in the warmer temperate parts of the globe. The **COMMON O.** (*O. Europæa*), a native of Syria and other Asiatic countries, and perhaps also of the south of Europe, although probably it is there rather naturalised than indigenous, is in its wild state a thorny shrub

Common Olive (*Olea Europæa*):

a, fruit reduced; b, flower; c, flower with corolla and stamens removed to shew the pistil.

or small tree, but through cultivation becomes a tree of 20–40 feet high, destitute of spines. It attains a prodigious age. The cultivated varieties are very numerous, differing in the breadth of the leaves, and in other characters. The leaves resemble those of a willow, are lanceolate, entire, of a dull dark-green colour above, scaly and whitish-gray beneath; the flowers small and white, in short dense racemes; the fruit greenish, whitish, violet, or even black, never larger than a pigeon's egg, generally oval, sometimes globular, or obovate, or acuminate. The fruit is produced in vast profusion, so that an old olive-tree becomes very valuable to its owner. It is chiefly from the pericarp that olive oil is obtained, not from the seed, contrary to the general rule of the vegetable kingdom. Olive oil is much used as an article of food in the countries in which it is produced, and to a smaller extent in other countries, to which it is exported also for medicinal and other uses (see **OILS**). Olives, gathered before they are quite ripe, are pickled

in various ways, being usually first steeped in lime-water, by which they are rendered softer and milder in taste. They are well known as a restorative of the palate, and are also said to promote digestion. Disagreeable as they generally are at first, they are soon greatly relished, and in the south of Europe are even a considerable article of food. Dried olives are there also used, as well as pickled olives.—The wood of the olive-tree takes a beautiful polish, and has black cloudy spots and veins on a greenish-yellow ground; it is principally used for the finest purposes by cabinet-makers and turners. The wood of the root is marked in a peculiarly beautiful manner, and is used for making snuff-boxes and small ornamental articles. The bark of the tree is bitter and astringent; and both it and the leaves have febrifuge properties. A gum resin exudes from old stems, which much resembles storax, has an odour like vanilla, and is used in all parts of Italy for perfumery.—Among the Greeks, the O. was sacred to Pallas Athene (Minerva), who was honoured as the bestower of it; it was also the emblem of chastity. A crown of olive-twigs was the highest distinction of a citizen who had merited well of his country, and the highest prize of the victor in the Olympic games. An olive branch was also the symbol of peace (compare Gen. viii. 11); and the vanquished, who came to supplicate for peace, bore olive-branches in their hands.—The O. has been cultivated in Syria, Palestine, and other parts of the east, from the earliest times. Its cultivation extends southwards as far as Cairo, and northwards to the middle of France. It is very generally propagated by suckers, but where great care is bestowed on it, inarching is practised. It grows from cuttings. The climate of England is too cold for the O., yet in Devonshire it ripens its fruit on a south wall.—*Olea similis* and several other species are useful trees of South Africa, yielding a very hard and extremely durable wood. Some of them bear the name of **IRONWOOD** at the Cape of Good Hope. The **AMERICAN O.** (*O. Americana*) is also remarkable for the hardness of its wood. It is found as far north as Virginia. It is a tree of 30–35 feet high, with much broader leaves than the Common Olive. Its fruit is fit for use. Its flowers are fragrant. The **FRAGRANT O.** (*O. fragrans*, or *Osmanthus fragrans*) of China and Japan has extremely fragrant flowers, which are used by the Chinese for flavouring tea.

O'LIVENITE, a mineral, consisting chiefly of arsenic acid and protoxide of copper, with a little phosphoric acid and a little water. It is generally of some dark shade of green, sometimes brown or yellow. It is found along with different ores of copper in Cornwall and elsewhere. It is often crystallised in oblique four-sided prisms, of which the extremities are acutely bevelled, and the obtuse lateral edges sometimes truncated, or in acute double four-sided pyramids; it is sometimes also spherical, kidney-shaped, columnar, or fibrous.

OLIVES, MOUNT or, called also **MOUNT OLIVET**, an inconsiderable ridge lying on the east side of Jerusalem, from which it is only separated by the narrow Valley of Jehosaphat. It is called by the modern Arabs Jebel-el-Tur, and takes its familiar name from a magnificent grove of olive-trees which once stood on its western flank, but has now in great part disappeared. The road to Mount Olivet is through St Stephen's Gate, and leads by a stone bridge over the now almost waterless brook Cedron. Immediately beyond, at the foot of the bridge, lies the Garden of Gethsemane; and the road here parts into two branches, northwards towards Galilee, and eastwards to Jericho. The

ridge rises in three peaks, the central one of which is 2556 feet above the level of the sea, and 416 feet above the Valley of Jehosaphat. The southern summit is now called 'the Mount of Offence,' and was the scene of the idolatrous worship established by Solomon for his foreign wives and concubines. The northern peak is the supposed scene of the appearance of the angels to the disciples after the resurrection, and is remarkable in Jewish history as the place in which Titus formed his encampment in the expedition against the fated city of Jerusalem. But it is around the central peak, which is the Mount of O. properly so called, that all the most sacred associations of Christian history converge. On the summit stands the Church of the Ascension, built originally by St Helen, the modern church being now in the hands of the Armenian community; and near it are shewn the various places where, according to tradition, our Lord wept over Jerusalem, where the apostles composed the apostles' creed, where our Lord taught them the Lord's Prayer, &c. Near the Church of the Ascension is a mosque and the tomb of a Mohammedan saint. In the Garden of Gethsemane, at the foot of the hill, is shewn the scene of our Lord's agony. The northern peak spreads out into a plain of considerable extent, which is painfully notable in Jewish history as the place where, after the Jews on occasion of the revolt under Bar-Kochab, were debarred by Adrian from entering Jerusalem, they were wont to assemble annually on the anniversary of the burning of the Temple to celebrate this mournful anniversary, and to take a distant look at their beloved Jerusalem. The scene is beautifully described, and with much dramatic feeling, by St Jerome.—*Com. in Sophoniam*, t. iii. p. 1665.

OLIVETANS, a religious order of the Roman Catholic Church, one of the many remarkable products of that well-known spiritual movement which characterised the 12th and 13th centuries. The O., or Brethren of Our Lady of Mount Olivet, are an offshoot of the great Benedictine Order (q. v.), and derive their origin from John Tolomei, a native of Siena, born in the year 1272. Tolomei had been a distinguished professor of philosophy in the university of his native city; but his career was suddenly interrupted by the loss of his sight. Although he was cured of his blindness (and, as he himself believed, miraculously), this visitation convinced him of the vanity of earthly things; and in company with some friends he withdrew to a solitary place near Siena, where he devoted himself to prayer and religious exercises. By the direction of the pope, John XXII., the new brethren adopted the Benedictine rule; but they chose as their especial province the cultivation of sacred science, and the duty of teaching. In the year 1319, Tolomei was chosen as the first general; and even in his lifetime the institute made rapid progress, especially in Italy. It numbered at one time eighty houses, but at present the number is reduced to four—namely, the parent house, so called, of Monte Oliveto, in the diocese of Arezzo in Tuscany, one at Rome, one at Genoa, and one at Palermo. The O. order has produced many distinguished ecclesiastics.

OLIVINE. See **CHRYSOLITE**.

OLLA PODRIDA (literally, *putrid pot*), a Spanish term, originally signifying an accumulation of remains of flesh, vegetables, &c., thrown together into a pot, but generally employed to designate a favourite national dish of the Spaniards, consisting of a mixture of different kinds of meat and vegetables stewed together. It has also come to be figuratively applied to literary productions of very miscellaneous contents. The French equivalent is

pot-pourri, and the Scotch *hotch-potch*, both of which, but especially the former, are also employed in a figurative sense.

OLMÜTZ, the chief fortress of Moravia, Austria, is the capital of a district of the same name, and is situated in lat. 49° 36' N., and in long. 17° 15' E., on an island of the river Morava, which, by means of sluices, can be opened into the moats, and thus made available for purposes of defence. O. is the see of an archbishop, nominated by the chapter, and is the chief seat of the administrative departments. Its university, founded in 1581, and reorganised in 1827, was reduced to a theological faculty in 1855. O. has a library of 65,000 vols.; good natural history, physical, and other museums; a gymnasium, an archiepiscopal seminary, artillery and infantry academies, polytechnic and other schools, a hospital, an asylum for widows and orphans, &c. The most noteworthy of its churches are the cathedral, a fine old building, and the church of St Mauritius, completed in 1412, with its celebrated organ, having 48 stops and more than 2000 pipes. The noble town-hall, with its complicated clock-work, set up in 1574, and the lofty column on the Oberring, with several fine fountains in the squares, and the splendid archiepiscopal palace and chapter-house, all contribute towards the picturesque aspect for which O. is distinguished. The deficiency in public gardens has of late years been in part supplied by the draining and planting of some of the inner moats, and the conversion of some portions of the fortifications into pleasure-grounds. A mile from the city lies the monastery of the Premonstratensians at Hradisch, founded in 1074, now a military hospital. O. has a few manufactories of kerseymer, cloth, linen, and porcelain, and is the seat of an extensive trade in cattle from Poland and Moldavia. Pop. (1880) 22,849. Prior to 1777, when O. was raised into an archbishopric, its bishops had long been in the enjoyment of the rank of princes of the empire. The city suffered severely during the Thirty Years' War, and again in the Seven Years' War of Silesia, when it more than once fell into the hands of the Prussians. In 1848, Ferdinand I. signed his abdication here in favour of his nephew, Franz-Joseph I.; while in 1850, O. was chosen as the place of conference between the Prussian, Austrian, and Russian plenipotentiaries, for the adjustment of the conflicting differences which had arisen in the German states generally, as the result of the revolutionary movement of 1848.

OLONETZ, a government in the north of Russia, bounded on the W. by Finland, and on the E. and N.E. by Archangel. Area, exclusive of water, 50,470 sq. miles. Pop. (1880) 314,500. Large lakes abound in this government, the chief, after Lake Onega (q. v.), being Lakes Wygo and Sego. The surface is in general elevated, and about four-fifths of it are covered with wood. The soil is sterile, and the climate is cold and damp. The wealth of the government consists principally in its minerals. Its iron-mines supply the iron-works of Petrasowodak, and from its quarries marbles are sent to St Petersburg. The principal employments of the inhabitants, who are principally Russians and Finns, and belong to the Greek Church, are carving in wood, fishing and hunting. Many of them also are employed in the ironworks and quarries. The women weave and spin. The government derives its name from the small but ancient town of Olonetz. Petrasowodak is the centre of administration.

OLORON, or **OLORON-SAINTE-MARIE**, a town of France, in the department of Basses-Pyrénées, on the Gave d'Oloron, 15 miles south-west of

Pau. Head-dresses are manufactured. Pop. 8000.

OLYMPIA, capital of Washington territory, U.S.A., at the head of an inlet from the south end of Puget's Sound, is becoming an important centre, especially since the opening of the North Pacific Railway. Pop. (1880) about 2000.

OLYMPIA, the scene of the celebrated Olympic Games (q. v.), is a beautiful valley in Elis, in the Peloponnesus, through which runs the river Alpheus. As a national sanctuary of the Greeks, O. contained, within a small space, many of the choicest treasures of Grecian art belonging to all periods and states, such as temples, monuments, altars, theatres, and multitudes of images, statues, and votive-offerings of brass and marble. In the time of the elder Pliny, there still stood here about 3000 statues. The Sacred Grove (called the *Altis*) of Olympia, enclosed a level space about 4000 feet long by nearly 2000 broad, containing both the spot appropriated to the games and the sanctuaries connected with them. It was finely wooded, and in its centre stood a clump of sycamores. The *Altis* was crossed from west to east by a road called the 'Pompic Way,' along which all the processions passed. The Alpheus bounded it on the south, the Cladeus, a tributary of the former, on the west, and rocky but gently swelling hills on the north; westward it looked towards the Ionian Sea. The most celebrated building was the *Olympieum*, or *Olympium*, dedicated to Olympian Zeus. It was designed by the architect Libon of Elis in the 6th c. B.C., but was not completed for more than a century. It contained a colossal statue of the god, the master-piece of the sculptor Phidias, and many other splendid figures; its paintings were the work of Panænus, a relative of Phidias. Next to the Olympieum ranked the *Heræum*, dedicated to Hera, the wife of Zeus, and the Queen of Heaven, containing the table on which were placed the garlands prepared for the victors in the games; the *Pelopieum*, the *Metroum*, the ten *Thesauri* or Treasuries, built for the reception of the dedicatory offerings of the Greek cities, the temples of Eileithyia and Aphrodite also deserve mention; the *Stadium* and the *Hippodrome*, where the contests took place, stood at the eastern end of the *Altis*. In 1875, explorations were undertaken by the German government at an annual expense of £8000, and threw much light on the plans of the buildings. Many valuable sculptures, bronzes, coins, and other objects were discovered. The third volume of *Excavations at Olympia* appeared in 1879.

OLYMPIAD (Gr. *olympias*), the name given to the period of four years that elapsed between two successive celebrations of the Olympic Games (q. v.); a mode of reckoning which forms the most celebrated chronological era among the Greeks. The first recorded olympiad dates from the 21st or 22d of July 776 B.C., and is frequently referred to as the Olympiad of Coræbus; for historians, instead of referring to the olympiad by its number, frequently designate it by the name of the winner of the foot-race in the Olympic games belonging to that period, though at times both the number and the name of the conqueror are given. A slight indefiniteness is frequently introduced into Greek chronology, from the custom of mentioning only the olympiad, neglecting to specify in which year of the olympiad a certain event happened. As this era commenced in 776 B.C., the first year of our present era (1 A.D.) corresponded to the last half of the fourth year of the 194th with the first half of the first year of the 195th olympiad, and 394 A.D. corresponds to the second year of the 293d olympiad, at which time reckoning by olympiads terminated. This era is used only by writers,

and is never found on coins, and very seldom on inscriptions. Another olympic era, known as the 'New Olympic Era,' was commenced by the Roman emperors, and dates from 131 A.D.; it is found both in writings, public documents, and inscriptions.

OLYMPIAS, the wife of Philip II., king of Macedon, and mother of Alexander the Great. She was the daughter of Neoptolemus I., king of Epirus. She possessed a vigorous understanding, but was of a most passionate, jealous, and ambitious character. Philip having, on account of disagreements, separated from her and married Cleopatra, niece of Attalus (337 B.C.), she went to reside with her brother Alexander, king of Epirus, where she incessantly fomented intrigues against her former husband, and is believed to have taken part in his assassination by Pausanias, 337 B.C. On the accession of her son Alexander to the throne, she returned to Macedonia, where she contributed to bring about the murder of Cleopatra and her daughter. Alexander was filled with indignation, but O. was his mother, and he could not obey the dictates of justice. During his brief but magnificent career he always treated her with the utmost reverence and esteem, though he never allowed her to meddle with his political schemes. After his death she endeavoured to get possession of the vacant throne, and obtained the support of Polyperchon in her designs. In 317, the two defeated Arrhidaeus, the weak-minded step-brother and successor of Alexander, and his wife Eurydice, whom she caused to be put to death in the same year. She now began to glut her revenge on such of the Macedonian nobles as had shewn themselves hostile to her; but her cruelties soon alienated the minds of the people from her, even though she was the mother of their heroic king, whereupon Cassander (q. v.), her principal adversary, marched north from the Peloponnesus, besieged her in Pydna, and forced her to surrender in the spring of 316 B.C. She was immediately afterwards put to death. O. was a woman of heroic spirit, but of fierce and uncontrollable passions, and in the perpetration of crime, when she reckoned it necessary, displayed an unscrupulousness peculiarly feminine.

OLYMPIC GAMES, the most splendid national festival of the ancient Greeks, were celebrated every fifth year in honour of Zeus, the father of the gods, on the plain of Olympia (q. v.). Their origin goes back into prehistoric ages. According to the myth elaborated or preserved by the Elean priests, they were instituted by the Itean Herakles in the time of Kronos, father of Zeus; according to others, by the later Herakles, son of Zeus and Alkmene; while Strabo, rejecting the older and more incredible legends, attributes their origin to the Herakleides after their conquest of the Peloponnesus. But the first glimpse of anything approaching to historic fact in connection with the games is their so-called revival by Iphitos, king of Elis, with the assistance of the Spartan lawgiver, Lycurgus, about 884 B.C.; or, according to others, about 828 B.C., an event commemorated by an inscription on a disc kept in the *Heræum* at Olympia, which Pausanias (flor. 2d c. A.D.) saw. That festive games were celebrated here, in other words, that Olympia was a sacred spot, long before the time of Iphitos, can indeed hardly be doubted: the universal tradition that the Elean king had only 'revived' the games proves this; but nothing whatever can be historically ascertained concerning their origin, character, or frequency, in this remoter time. Iphitos may, therefore, be regarded as their founder, yet the reckoning of time by Olympiads (q. v.)—the real dawn of the historical period in Greek history—did not begin till more than a century later. At

first, it is conjectured, only Peloponnesians resorted to the Olympic games, but gradually the other Greek states were attracted to them, and the festival became *Pan-Hellenic*. Originally, and for a long time, none were allowed to contend except those of pure Hellenic blood; but after the conquest of Greece by the Romans, the latter sought and obtained this honour, and both Tiberius and Nero figure in the list of Roman victors. Women—with one exception, the priestess of Demeter Chamyne—were forbidden to be present, on pain of being thrown headlong from the Typsean Rock. The games were held from the 11th to the 15th of the Attic month *Hekatombaion* (our July—August), during which, first throughout Elis, and then throughout the rest of Greece, heralds proclaimed the cessation of all intestine hostilities; while the territory of Elis itself was declared inviolable. The combatants were required to undergo a preparatory training for ten months in the gymnasium at Elis, and during the last of these months the gymnasium was almost as numerously attended as the games themselves. Much uncertainty prevails as to the manner in which the contests were distributed over the different days. Krause (*Olympia*, p. 106) suggests the following order: On the first day the great initiatory sacrifices were offered, after which the competitors were properly classed and arranged by the judges, and the contests of the trumpeters took place; the second day was set apart for the boys who competed with each other in foot-races, wrestling, boxing, the pentathlon, the pankration, horse-races; the third and principal day was devoted to the contests of men in foot-races of different kinds (as, for example, the simple race, once over the course; the *diakulos*, in which the competitors had to run the distance twice; and the *dolichos*, in which they had to run it seven or twelve times); wrestling, boxing, the *pankration* (in which all the powers and skill of the combatants were exhibited), and the race of *hoplites*, or men in heavy armour; on the fourth day came off the *pentathlon* (contest of five games—viz, leaping, running, throwing the discus, throwing the spear, and wrestling), the chariot and horse races, and perhaps the contests of the heralds; the fifth day was set apart for processions, sacrifices, and banquets to the victors (called *Olympionikoi*), who were crowned with a garland of wild olive twigs cut from a sacred tree which grew in the Altis (see *OLYMPIA*), and presented to the assembled people, each with a palm branch in his hand, while the heralds proclaimed his name, and that of his father and country. On his return home, he was received with extraordinary distinction: songs were sung in his praise (14 of Pindar's extant lyrics are devoted to *Olympionikoi*); statues were erected to him, both in the Altis and in his native city; a place of honour was given him at all public spectacles; he was in general exempted from public taxes, and at Athens was boarded at the expense of the state in the Prytaneion.

The regulation of the games belonged to the Eleans, from whom were chosen the *hellanodikai*, or judges, whose number varied. At first there were only two, but as the games became more and more national, and consequently more numerous, they were gradually increased to ten, sometimes even to twelve. They were instructed in their duties for ten months beforehand at Elis, and held their office only for one year. The officers who executed their commands were called *alytai*, and were under the presidency of an *alytarch*.—See Krause's *Olympia oder Darstellung der grossen Olympischen spiele* (1838) and Böttcher's work (1882).

OLYMPIODORUS, one of the latest of the Alexandrian Neoplatonists, flourished in the first

half of the 6th c. after Christ, during the reign of the Emperor Justinian. Regarding his life nothing is known. Of his writings, we possess a *Life of Plato*, with commentaries or scholia on several of his dialogues, the *Gorgias*, *Philebus*, *Phædo*, and *Alcibiades I*. In these he appears as an acute and vigorous thinker, and as a man of great erudition. —Another O., of the Peripatetic school, flourished in Alexandria in the 5th c. B.C., and was the teacher of Proclus (q. v.). —A third O., from Thebes in Egypt, wrote a history in the first half of the 5th c. A.D.

OLYMPUS, the ancient name of several mountains or chains of mountains—e. g., of the north-western continuation of Taurus in Mysia, of a mountain in the island of Cyprus, of one in Lycia, of another in Elis, of one on the borders of Laconia and Arcadia, and of another on the frontiers of Thessaly and Macedonia. Of these, the last-mentioned (now called *Elymbo*) is the most famous. Its eastern side, which fronts the sea, is composed of a line of vast precipices, cleft by ravines, filled with forest-trees. Oak, chestnut, beech, plane tree, are scattered abundantly along its base, and higher up appear great forests of pine, as in the days of the old poets of Greece and Rome. With Euripides, it is *poludendros Olympos*; with Virgil, *frondosus Olympus*; and with Horace, *opacus Olympus*. Its highest peak is 9754 feet above the level of the sea, and is covered with snow for about nine months of the year. It was regarded by the ancient Greeks as the chief abode of the gods, and the palace of Zeus was supposed to be upon its broad summit. According to Greek legend, it was formerly connected with Ossa, but was separated from it by an earthquake, allowing a passage for the Peneius through the narrow vale of Tempe to the sea. The philosophers afterwards transferred the abode of the gods to the planetary spheres, to which they likewise transferred the name of Olympus.

OM is a Sanscrit word which, on account of the mystical notions that even at an early date of Hindu civilisation were connected with it, acquired much importance in the development of Hindu religion. Its original sense is that of emphatic or solemn affirmation or assent. Thus, when in the White-Yajur-Veda (see *VEDA*) the sacrificer invites the gods to rejoice in his sacrifice, the god Savitrî assents to his summons by saying: 'Om (i. e., be it so); proceed!' Or, when in the Brîhad-Aranyaka-Upanishad, Prajâpati, the father of gods, men, and demons, asks the gods whether they have understood his instruction; he expresses his satisfaction with their affirmative reply, in these words: 'Om, you have fully comprehended it;' and, in the same Upanishad, Pravâhan's answers the question of Śvetaketu, as to whether his father has instructed him, by uttering the word 'Om,' i. e., 'forsooth (I am).' A portion of the Rîgveda, called the Aitareya-Brâhman'a, where describing a religious ceremony at which verses from the Rîgveda, as well as songs called Gâthâs, were recited by the priest called Hotrî, and responses given by another priest, the Adhvaryu, says: 'Om is the response of the Adhvaryu to the Rîgveda verses (recited by the Hotrî), and likewise *tathâ* (i. e., thus) his response to the Gâthâs, for Om is (the term of assent) used by the gods, whereas *tathâ* is (the term of assent) used by men' (the Rîgveda verses being, to the orthodox Hindu, of divine, and the Gâthâs of human, authorship). In this, the original sense of the word, it is little doubtful that om is but an older and contracted form of the common Sanscrit word *avam*, 'thus,' which, coming from the pronominal base 'a'—in some derivations changed to 'e'—may have at one time occurred in the form *avam*, when, by the elision

of the vowel following *u*—for which there are numerous analogies in Sanscrit—*avam* would become *aum*, and hence, according to the ordinary phonetic laws of the language, *om*. This etymology of the word, however, seems to have been lost, even at an early period of Sanscrit literature; for another is met with in the ancient grammarians, enabling us to account for the mysticism which many religious and theological works of ancient and medieval India suppose to inhere in it. According to this latter etymology, *om* would come from a radical *av* by means of an affix *man*, when *om* would be a curtailed form of *aman* or *oman*; and as *av* implies the notion of 'protect, preserve, save,' *om* would be a term implying 'protection or salvation'; its mystical properties and its sanctity being inferred from its occurrence in the Vedic writings, and in connection with sacrificial acts, such as are alluded to before.

Hence *Om* became the auspicious word with which the spiritual teacher had to begin, and the pupil had to end each lesson of his reading of the Veda. 'Let this syllable,' the existing *Prātisūkhya*, or grammar of the R'igveda, enjoins, 'be the head of the reading of the Veda, for alike to the teacher and the pupil, it is the supreme Brahman, the gate of heaven.' And Manu (q. v.) ordains: 'A Brahman, at the beginning and end (of a lesson on the Veda), must always pronounce the syllable *Om*; for unless *Om* precede, his learning will slip away from him; and unless it follow, nothing will be long retained.' At the time when another class of writings, the Purāṇas (q. v.), were added to the inspired code of Hinduism, for a similar reason, *Om* is their introductory word.

That the mysterious power which, as the foregoing quotation from the law-book of Manu shews, was attributed to this word, must have been the subject of early speculation, is obvious enough. A reason assigned for it is given by Manu himself. 'Brahmā,' he says, 'extracted from the three Vedas the letter *a*, the letter *u*, and the letter *m* (which combined result in *Om*), together with the (mysterious) words *Bhūh* (earth), *Bhuvah* (sky), and *Swah* (heaven);' and in another verse: 'These three great immutable words, preceded by the syllable *Om*, and (the sacred R'igveda verse, called) *Gāyatrī*, consisting of three lines, must be considered as the mouth (or entrance) of Brahman (the Veda)'—or, as the commentators observe—the means of attaining final emancipation; and 'The syllable *Om* is the supreme Brahman, (three) regulated breathings (accompanied with the mental recitation of *Om*, the three mysterious words, *Bhūh*, *Bhuvah*, *Swah*, and the *Gāyatrī*), are the highest devotion. . . . All rites ordained in the Veda, such as burnt and other sacrifices, pass away; but the syllable *Om* must be considered as imperishable, for it is (a symbol of) Brahman (the supreme Spirit) himself, the Lord of Creation.' In these speculations, Manu bears out, and is borne out by, several Upanishads. See *VEDA*. In the *Kathu-Upanishad*, for instance, *Yama*, the god of death, in replying to a question of *Nachiketas*, says: 'The word which all the Vedas record, which all the modes of penance proclaim, of which desirous the religious students perform their duties, this word I will briefly tell thee, it is *Om*. This syllable means the (inferior) Brahman and the supreme (Brahman). Whoever knows this syllable, obtains whatever he wishes.' And in the *Prasna-Upanishad*, the saint *Pippalāda* says to *Satyakāma*: 'The supreme and the inferior Brahman are both the word *Om*; hence the wise follows by this support the one or the other of the two. If he meditates upon its one letter (*a*) only, he is quickly born on the earth; him carry the verses of the R'igveda to the world of man; and if

he is devoted there to austerity, the duties of a religious student, and faith, he enjoys greatness. But, if he meditates in his mind on its two letters (*a* and *u*), he is elevated by the verses of the *Yajur-Veda* to the intermediate region; he comes to the world of the moon, and having enjoyed there power, returns again (to the world of man). If, however, he meditates on the supreme Spirit by means of its three letters (*a*, *u*, and *m*), he is produced in light, in the sun; as the snake is liberated from its skin, so he is liberated from sin.' According to the *Mān'dūkya-Upanishad*, the nature of the soul is summarised in the three letters *a*, *u*, and *m*, in their isolated and combined form—*a* being *Vaisvānara*, or that form of Brahman which represents the soul in its waking condition; *u*, *Taijasa*, or that form of Brahman which represents it in its dreaming state; and *m*, *Prājna*, or that form of Brahman which represents it in its state of profound sleep (or that state in which it is temporarily united with the supreme Spirit); while *a*, *u*, *m* combined, i. e., *Om*, represent the fourth or highest condition of Brahman, 'which is unaccountable, in which all manifestations have ceased, which is blissful and without duality. *Om*, therefore, is soul; and by this soul, he who knows it enters into (the supreme) soul.' Passages like these may be considered as the key to the more enigmatic expressions used, for instance, by the author of the *Yoga* (q. v.) philosophy, where, in three short sentences, he says: 'His (the supreme Lord's name) is *Pranava* (i. e., *Om*); its muttering (should be made) and reflection on its signification; thence comes the knowledge of the transcendental spirit, and the absence of the obstacles' (such as sickness, languor, doubt, &c., which obstruct the mind of an ascetic). But they indicate, at the same time, the further course which superstition took in enlarging upon the mysticism of the doctrine of the Upanishads. For as soon as every letter of which the word *Om* consists was fancied to embody a separate idea, it is intelligible that other sectarian explanations were grafted on them, to serve their special purposes. Thus, while *S'ankara*, the great theologian and commentator on the Upanishads, is still contented with an etymological punning, by means of which he transforms '*a*' (or rather '*d*') into an abbreviation of *apti* (pervading), since speech is pervaded by *Vaisvānara*; '*u*' into an abbreviation of *ulkarsha* (superiority), since *Taijasa* is superior to *Vaisvānara*; and '*m*' into an abbreviation of *miti* (destruction), *Vaisvānara* and *Taijasa*, at the destruction and regeneration of the world, being, as it were, absorbed into *Prājna*—the Purāṇas (q. v.) make of '*a*' a name of *Vishṇu*; of '*u*' a name of his consort *S'ri*; and of '*m*,' a designation of their joint-worshipper; or they see in *a*, *u*, *m* the Triad, *Brahmā*, *Vishṇu*, and *S'iva*; the first being represented by '*a*,' the second by '*u*,' and the third by '*m*'—each sect, of course, identifying the combination of these letters, or *Om*, with their supreme deity. Thus, also, in the *Bhagavadgītā*, which is devoted to the worship of *Vishṇu* in his incarnation as *Krishṇa*, though it is essentially a poem of philosophical tendencies, based on the doctrine of the *Yoga*, *Krishṇa* in one passage says of himself that he is *Om*; while, in another passage, he qualifies the latter as the supreme Spirit.—A common designation of the word *Om*—for instance, in the last-named passages of the *Bhagavadgītā*—is the word *Pranava*, which comes from a so-called radical *nu*, 'praise,' with the prefix *pra*, amongst other meanings, implying emphasis, and therefore literally means 'eulogium, emphatic praise.' Although *Om*, in its original sense, as a word of solemn or emphatic assent, is, properly speaking, restricted to the Vedic literature, it deserves notice

that it is now-a-days often used by the natives of India in the sense of 'yes,' without, of course, any allusion to the mystical properties which are ascribed to it in the religious works. See also the article OM MANI PADME HŪM'.

That there exists no connection whatever, as has been supposed by some writers to be the case, between *Om* and *Amen*, requires scarcely any remark, after the etymological explanations given above; but it may not be without interest to observe that, though the derivation of *Om*, as a curtailment of *av-man*, from *av*, 'protect, save,' is probably merely artificial, and, as stated before, invented to explain the later mystical use of the Vedic word, it seems more satisfactory to compare the Latin *omen* with a Sanscrit *avman*, 'protection,' as derived by the grammarians from *āv* (in the Latin *āve-o*), than to explain it in the fashion of the Roman etymologists: 'Omen, quod ex ore primum elatum est, omen dictum;' or, 'Omen velut orem, quod fit ore augurium, quod non avibus aliove modo fit.' And since *pra-nava*, from Sanscrit *nu*, 'praise,' is, like *Om*, used in the sense of 'the deity,' it is likewise probable that *numen* does not come, as is generally believed, from Latin *nu-(ere)*, 'nod,' but from a radical corresponding with the Sanscrit *nu*, 'praise.'

OM MANI PADME HŪM' is the 'formula of six syllables' which has acquired much celebrity from the conspicuous part which it plays in the religion of the Buddhists, and especially in that form of it called *Lamaism* (q.v.). It is the first subject which the Tibetans and Mongols teach their children, and it is the last prayer which is muttered by the dying man; the traveller repeats this formula on his journey, the shepherd when attending his flock, the housewife when performing her domestic duties, the monk when absorbed in religious meditation, &c. It is met with everywhere; on flags, rocks, trees, walls, columns, stone-monuments, domestic implements, skulls, skeletons, &c. It is looked upon as the essence of all religion and wisdom, and the means of attaining eternal bliss. 'These six syllables,' it is said, 'concentrate in themselves the favour of all the Buddhas, and they are the root of the whole doctrine . . . ; they lead the believer to re-birth as a higher being, and are the door which bars from him inferior births; they are the torch which illuminates darkness, the conqueror of the five evils;' &c. They are likewise the *symbol* of transmigration; each syllable successively corresponding with, and releasing from, one of the six worlds in which men are reborn; or they are the mystical designation of the six transcendental virtues, each successive syllable implying self-offering (*dāna*), endurance (*keśānti*), chastity (*śīla*), contemplation (*dhyāna*), mental energy (*vīrya*), and religious wisdom (*prajñā*). The reputed author of this formula is the Dhyāni-Bodhisattwa, or deified saint, *Avalokites'vara*, or, as the Tibetans call him, *Padmapānī*' (i. e., the lotus-handed). It would not belong, accordingly, to the earliest stage of Buddhism, nor is it found in the oldest Buddhist works of the north of India or of Ceylon. Its original sense is rather obscure. Some suppose that it means O! (*om*), the jewel (*man*'s) in the lotus (*padme*), amen (*hūm*); 'the jewel' being an allusion to the saint *Avalokites'vara* himself, and the word '*padme*, or in the lotus,' to the belief that he was born from a lotus. It is probably, however, more correct to interpret the formula thus: 'Salvation (*om*) [is] in the jewel-lotus (*man*'s-*padme*), amen (*hūm*);' when the compound word 'jewel-lotus' would mean the saint and the flower whence he arose. If this interpretation be correct, the formula would be originally nothing more than

a salutation addressed to *Avalokites'vara* or *Padmapānī*; and the mystical interpretation put upon each syllable of it, would then be analogous to that which imparted a transcendental sense to each of the letters of the syllable *Om* (q. v.). Dr Emil Schlagintweit, in his valuable work on *Buddhism in Tibet* (Leipzig, 1863), relates (p. 120) that 'in a prayer-cylinder which he had the opportunity of opening, he found the formula printed in six lines, and repeated innumerable times upon a leaf 49 feet long and 4 inches broad. When Baron Schilling de Canstadt paid a visit to the temple Subulin, in Siberia, the Lamas were just occupied with preparing 100,000,000 of copies of this prayer to be put into a prayer-cylinder; his offer to have the necessary number executed at St Petersburg was most readily accepted, and he was presented, in return for the 150,000,000 of copies he forwarded to them, with an edition of the Kanjur, the sheets of which amount to about 40,000. When adorning the head of religious books, or when engraved upon the slabs resting on the prayer-walls, the letters of the formula are often so combined as to form an anagram. The longitudinal lines occurring in the letters '*man*'s *padme hūm*' are traced close to each other, and to the outer longitudinal line at the left are appended the curved lines. The letter '*om*' is replaced by a symbolical sign above the anagram, shewing a half-moon surmounted by a disc indicating the sun, from which issues a flame. Such a combination of the letters is called in Tibetan *nam chu vangdan*, "the ten entirely powerful (viz, characters, six of which are consonants, and four vowels);" and the power of this sacred sentence is supposed to be increased by its being written in this form. These kind of anagrams are always bordered by a pointed frame indicating the leaf of a fig-tree."—See also E. Burnouf, *Introduction à l'Histoire du Bouddhisme Indien* (Paris, 1844); C. F. Koepfen, *Die Religion des Buddha* (Berlin, 1857—1859); and the works quoted by these authors.

OMA'GH (Irish, *Oigh magh*, 'seat of the chiefs'), an ancient town, capital of the county of Tyrone in Ireland, situated on the river Strule, distant 34 miles south from Londonderry, and 110 miles north-west from Dublin, with both which cities it is connected by railway. O. grew up around an abbey founded in the year 792, but is first heard of as a fortress of Art O'Nial in the end of the 15th c., about which time it was forced to surrender to the English, although its possession long continued to alternate between Irish and English hands. It formed part of James I.'s 'Plantation' grants, and was strongly garrisoned by Mountjoy. On its being evacuated by the troops of James II. in 1689, it was partially burned, and a second fire in 1743 completed its destruction. But it has been well rebuilt, and is now a neat and prosperous town. Pop. (1881) 4126. O. contains a very handsome court-house, where the assizes for County Tyrone are held, several neat churches (Roman Catholic, Episcopal, and Presbyterian), a convent, several partially endowed and national schools, a district lunatic asylum, and the workhouse of the Poor-Law Union of which it is the centre. There is also a barrack station—it being within the Belfast military district. Its trade is chiefly in brown linens, corn, and agricultural produce.

O'MAHA CITY, the chief city of the state of Nebraska, U. S., is on the right bank of the Missouri, opposite Council Bluffs, and 20 miles north of the mouth of the Nebraska River. Besides the government offices, it has a large trade by the rivers, and across the prairies, and is the eastern terminus of the Union Pacific Railway, and also of the Omaha

and North-western, and the Omaha and South-western lines. Pop. (1860) 1912; (1870) 16,083; (1880) 30,518.

OMAN, the most eastern portion of Arabia, a strip of maritime territory, extending between Ras-el-Jiboul and Ras-el-Had, bounded on the north-east by the Gulf of Oman, and on the south-west by the deserts of the interior. It is about 370 miles in length; its greatest breadth is 120 miles. At a distance of from 20 to 40 miles from the coast, a chain of mountains runs parallel to it, which reaches in its highest ridge, called *Gebel Achdar* ('Great Mountain'), an elevation of 6000 feet; the average height is 4000 feet. There are a few not inconsiderable streams, and some richly fertile tracts in this region, but the greater part is a waste of sand, with here and there a small oasis, where, however, the vegetation is most luxuriant. Groves of almond, fig, and walnut-trees, tower to an enormous height, overshadowing the orange and citron trees, but are themselves overtopped by the splendid date-palma. The most powerful state of O. is *Muscat* (q. v.).

OMAR, ABŪ-HAFSA-IBN-AL-KHETTAB, the second calif of the Moslems, was born about 581. His early history is little known, but previous to his conversion he was an ardent persecutor of Mohammed and his followers. After his conversion he became as zealous an apostle as he had formerly been a persecutor, and rendered valuable aid to the prophet in all his warlike expeditions. After Mohammed's death, he caused Abu-bekr to be proclaimed calif, and was himself appointed *haujeb*, or prime-minister. Though of a fiery and enthusiastic temperament, he proved a sagacious adviser, and it was at his suggestion that the calif put down with an iron hand the many dissensions which had arisen among the Arabs after the prophet's decease, and resolved to strengthen and consolidate their new-born national spirit, as well as propagate the doctrines of Islam, by engaging them in continual aggressive wars. On the death of Abu-bekr, O. succeeded as calif, and pushed on the wars of conquest with increased vigour. He was summoned to Jerusalem in 637, to receive the keys of that city, and before leaving gave orders to build a mosque, now called by his name, on the site of the temple of Solomon. O. now took the command of a portion of the army, and reduced the other chief cities of Palestine. He then planned an invasion of Persia, which was commenced the same year, and by 642 the whole of what is now known as Persia was subdued. In the meantime the war in Syria was vigorously prosecuted, and the Byzantine armies, repeatedly defeated, at length gave up the contest. In 639, Amrŭ, one of his generals, had invaded Egypt with a considerable force; but such was the prestige of the Arabs, or the incapacity of the lieutenants of the Emperor Heraclius, that this valuable country, with its six millions of people, was reduced under the calif's authority without a single contest, and only two towns, Mir and Alexandria, were even attempted to be defended. (For the story which was till lately believed concerning the destruction of the Alexandrian Library, see ALEXANDRIAN LIBRARY.) Barca and Tripoli were next subdued by Amrŭ. On the north, Armenia was overrun in 641, and the calif's authority now reached from the Desert of Khiva to the Syrtis, an enormous extension in ten years. In 644, O. was assassinated in the mosque of Medina by a Persian slave from motives of revenge. He languished five days after receiving the wound, but refused to appoint a successor, and named six commissioners who were to choose one from themselves. He was buried in the mosque of

Medina, near the prophet and Abu-bekr, and his tomb is still visited by pilgrims.

O. may be called the founder of the Mohammedan power, as from a mere sect he raised it to the rank of a conquering nation, and left to his successor an empire which Alexander the Great might have envied. In him we find a rare combination of qualities, the ardent zeal of the apostle side by side with the cautious foresight and calm resolution of the monarch. His great military talents, and severity to 'obstinate unbelievers,' rendered him formidable to his enemies, and his inexorable justice rendered him no less obnoxious to the more powerful of his subjects, and gave rise to many attempts at his assassination. O. was the founder of many excellent institutions; he assigned a regular pay to his soldiers, established a night-police in towns, and made some excellent regulations for the more lenient treatment of slaves. He also originated the practice of dating from the era of the *Hejrah* (q. v.). He assumed the title of *Emir-al-mumenin* ('Commander of the Faithful') in preference to that of *Khalifah-rasouli-Nabi*, the ordinary designation; and to the present day his name is held in the greatest veneration by the orthodox or Suni sect of Moslems.

OMAR PASHA, a celebrated Turkish general, was born at Plaski, an Austrian village in the Croatian Military Frontier, in 1806 (according to some authorities, in 1811). His real name was Mikail Lattas, and his father being an officer in the Austrian army, Mikail was educated at the military school of Thurn, near Carlsstadt, where he greatly distinguished himself. He afterwards joined one of the frontier regiments as a cadet, and was employed as secretary by the military inspector of roads and bridges; but having by some breach of discipline rendered himself amenable to punishment, he fled to Bosnia, where he became book-keeper to a Turkish merchant, and embraced Mohammedanism. He was next employed by Hussein Pasha, the governor of Widin, as tutor to his sons; and in 1834 was sent in charge of them to Constantinople, where his beautiful calligraphy gained for him the post of writing-master in the military school. Omar Effendi (as he was now called) was next appointed writing-master to Abdul-Medjid, the heir to the throne, and received the honorary rank of captain in the Turkish army, and the hand of a rich heiress. On his pupil's accession in 1839, O. was raised to the rank of colonel, and sent to Syria to aid in the suppression of disturbances which had broken out in that province, and in 1842 he was appointed military governor of the Lebanon district. The severity of his rule did not hinder the Maronites from desiring to have him as chief of the Mountain; but in the following year he was recalled, received the title of pasha, and was sent, along with Redeschid Pasha, against the revolted Albanians. The skill and energy with which he suppressed this insurrection, as well as others in Bosnia and Kurdistan, raised him high in favour with the sultan. Towards the end of 1852 he opened the campaign against the Montenegrins, who were being rapidly subdued, when Austria interfered and compelled a treaty. On the invasion of the Principalities by the Russians (July 1853), O. collected at Schumla an army of 60,000 men to cover Constantinople; but being no less a politician than a soldier, he soon divined that the Russians would not immediately cross the Danube, and accordingly pushed on to Widin, where he crossed the river in presence of the enemy and intrenched himself at Kalafat. Another part of the Turkish army moved down the Danube to Turtukai, near Silistria, crossed the river at that

place, and intrenched themselves at Oltenitza. On November 4, the latter division were attacked by 9000 Russians, whom they totally defeated with a loss of nearly 4000 men and almost all their officers. The Russians also received two severe checks at Kalafat, on January 6 and March 15, 1855. O. kept up the spirit of his troops by occasional successful skirmishes with the Russians, and threw a garrison of 8000 men into Silistria. In the following spring the Russians passed the Danube at two points, and laid siege to Silistria (q. v.), but their assaults were invariably repulsed with severe loss. The Russians then withdrew from the Principalities, and O. entered Bucharest in triumph in August 1854. On 9th February 1855, he embarked for Eupatoria, where, on the 17th of the same month, he was suddenly attacked by 40,000 Russians, who were repulsed with great loss. He was soon afterwards (October 3, 1855) sent to relieve Kars, but arrived too late, and the armistice which followed (February 29, 1856) put a stop to his military career. He was subsequently made governor of Bagdad; but having been accused of maladministration, was banished to Kaarport in 1859. He was recalled in the following year, and in September 1861 was sent to pacify Bosnia and Herzegovina, which were again in insurrection. This being accomplished, he attacked the Montenegrins, captured their chief town of Cetinji, and overran the country in 1862. O. held the Grand-cross of the Legion of Honour, and was a Knight of the Russian Order of St. Anna. He ceased to take part in public life in 1869, being thereafter regarded as a minister without portfolio; and died in 1871.

OMBAY, or MALOEWA (Maluwa), an island between Celebes and the north-west coast of Australia, lies to the north of Timor, from which it is separated by the Strait of Ombay, lat. 8° 8'—8° 28' S., long. 124° 17'—125° 7' E. Area, 961 square miles. The population amounts to about 193,800. The hills of O. are volcanic, and the coasts steep and difficult to approach. The inhabitants are dark brown, have thick lips, flat nose, and woolly hair; appearing to be of mixed Negro and Malay origin. They are armed with the bow, spear, and creese, and live on the produce of the chase, with fish, cocoa-nuts, rice, and honey. A portion of the island formerly belonged to the Portuguese, but since August 6, 1851, it is entirely a Netherlands possession. The Dutch postholder resides at the village of Alor, to which iron wares, cotton goods, &c., are brought from Timor, and exchanged for wax, edible nests, provisions, and other native products. O. has oxen, swine, goats, &c., and produces maize, cotton, and pepper. Amber is also found, and the Boeginese of Celebes import European and Indian fabrics, exchanging them for the produce of the island, which they carry to Singapore.

O'MEARA, BARRY EDWARD, was born in Ireland in the year 1786. Otherwise without claim to be remembered, his name remains notable from his connection with the first Napoleon, whom he accompanied to St Helena as household physician. At the age of 18 he entered the British army as assistant-surgeon. In 1808, being stationed at Messina, he became concerned in a duel as second, under circumstances which must more or less have been held discreditable, as his dismissal from the service by sentence of court-martial was the result. Afterwards he succeeded in procuring an appointment as surgeon in the navy, and as such for some years is certified to have discharged his duties with zeal and efficiency. As it chanced, he was serving with Captain Maitland in the Bellerophon when the Emperor Napoleon (q. v.) surrendered himself to

that officer. During the voyage from Rochefort to Plymouth he was introduced to Napoleon, on whom the impression he produced was favourable, leading to a proposal that he should accompany the emperor into exile as private physician, an arrangement to which he acceded, stipulating that he should retain his rank in the navy, and be permitted to return to it at pleasure. By Napoleon, with whom he remained in daily intercourse at St Helena for about three years, he seems to have been admitted to something more or less like intimacy; and occasionally it might well be, as he says, that the great captive would kill the creeping hours by loose talk with his attendant over the events of his strange life. Of these conversations O'M. naturally enough took notes, which he afterwards published. Meantime he became involved in the interest of Napoleon, in the series of miserable and petty squabbles which he waged with the governor, Sir Hudson Lowe (q. v.). The result of these, as regards O'M., was that in 1818, after a violent altercation with Sir Hudson, he was committed to close arrest, and was authorised by the emperor to resign his post. On his return to England, he addressed a letter to the Admiralty, in which, among other things, he accused Sir Hudson Lowe of intentions against the life of his captive, and even of having, by dark hints to himself, insinuated a desire for his services as secret assassin. For this he was instantly dismissed the service. The accusation was plainly monstrous and incredible. In 1822, after Napoleon's death, O'M. published *Napoleon in Exile*, by which book alone he is now remembered. As conveying to the world the first authentic details of the prison-life of the great deceased, it made on its appearance an immense sensation, and—though for obvious reasons everywhere to be accepted, if at all, with caution—it is still not utterly without interest. The last years of O'M.'s life were passed in obscurity in the neighbourhood of London, where, in 1836, he died.

O'MELET, or OMELETTE, French, a dish chiefly composed of eggs. These are broken, and their contents put into a proper vessel, in which they are whipped into a froth, which is poured into a very clean and dry frying-pan, with the addition of lard or butter to prevent sticking, and then fried carefully, so that the outside is nicely browned. Before frying, one of a number of ingredients may be added to vary the omelette, such as chopped savoury herbs, minced ham or bacon, salt-fish, shell-fish, game, &c. Or sweet omelettes may be made by placing preserved fruits upon them when quite or nearly cooked. The omelette is an excellent dish, and, simple though it be, it requires much skill to prepare it successfully.

O'MEN (for the deriv., see OM), or PRODIGY (generally said to be from *pro* and *disco*, but more probably from *pro* and *ago*, to lead; hence anything conspicuous, or extraordinary), the name given by the Romans to signs by which approaching good or bad fortune was supposed to be indicated. The terms *Omen* and *Prodigy* were not, however, exactly synonymous; the former being applied rather to signs received by the ear, and particularly to spoken words; the latter to phenomena and occurrences, such as monstrous births, the appearance of snakes, locusts, &c., the striking of the foot against a stone or the like, the breaking of a shoe-tie, and even sneezing, &c. If an omen or prodigy was promised on the part of a god, it was to be interpreted according to the promise; but otherwise, the interpretation was extremely arbitrary. It was supposed that evil indicated as approaching might be averted by various means, as by sacrifices,

or by the utterance of certain magic formulas; or by an extempore felicity of interpretation, as when Cæsar, having fallen to the ground on landing in Africa, exclaimed: 'I take possession of thee, Africa.' Occasionally, it is true, we read of a reckless disregard of omens; as, for example, when P. Claudius, in the First Punic War, caused the sacred chickens, who would not leave their cage, to be pitched into the sea, saying: 'If they won't eat, they must drink.' Still the belief in them was universal, and in general the greatest care was taken to avoid unfavourable omens. The heads of the sacrificial priests were covered, so that nothing distracting might catch their eyes; silence was enjoined at the commencement of every sacred undertaking, and at the opening of the *Ludi*. Before every sacrificial procession ran the heralds, calling on the people to 'pay respect to it,' and admonishing them to cease working till it should have passed, that the priests might not hear unfavourable sounds. At the beginning of a sacrifice, the bystanders were addressed in the words *Favete Linguis* ('Speak no word of evil import'), and the aid of music was sought to drown whatever noises might prove unpropitious. Compare *AUGURIES* AND *AUSPICES*, and *DIVINATION*. See also Fallati, *Ueber Begriff und Wesen des Rom. Omen* (Tüb. 1836).

The belief in omens has existed in all ages and countries, and traces of it linger even yet in the most civilised communities; in the dread, for instance, that many entertain at sitting down to table in a party of thirteen. Not a little of the philosophy of omens is contained in the Scottish proverb: 'Them who follow freits, freits follow;' meaning, that a fatalistic belief in impending evil paralyses the endeavour that might prevent it.

OMENTUM. See PERITONEUM.

OMMI'ADES (Omaïades, or Ommeyyades), a dynasty (deriving its name from an ancestor, Ommeyyah) which succeeded to the Arabian califate on the death of Ali, the fourth calif after Mohammed, and possessed it till superseded by the Abbasides (q. v.) in 750. Moawiyah, the founder of the dynasty, was the son of Abu-Sofian, who defeated Mohammed at Beder, and his mother was the notorious Hinda. After the death of Othman the third calif, Moawiyah, who was his cousin, claimed the throne, and during the whole of Ali's reign ruled over the western provinces of Syria and Egypt; but it was not till the death of that calif, and the abdication of his son Hassan in 661, that MOAWIYAH's authority was fully recognised. In that year he transferred the seat of the califate to Damascus; Kufa having been the residence of Ali, and Medina of the first three califs. The Arabs continued to extend their conquests during his reign; the Turks in Khorassan were subdued, Turkestan invaded, and several important acquisitions made in Asia Minor. But besides aggrandising his empire, the calif neglected no means of consolidating it, and partly for this reason he made the succession hereditary, and caused his son YEZID (680—683) to be recognised as his heir. The reigns of Yezid and his successors, MOAWIYAH II. (683) and MERWÂN I., formerly the traitorous secretary of the calif Othman (683—685), are devoid of importance, as their sway extended only over Syria and Palestine. ABDULMELEK (685—705), an able and warlike prince, after a long and varying struggle of eight years, succeeded in rendering himself undisputed ruler of the Mohammedan world (692), but the latter part of his reign was much disturbed by rebellions in the eastern provinces. He was the first calif who interested himself in the promotion of liberal knowledge, by causing the most celebrated

poetical and other works of the Persians to be translated into Arabic; and under his reign coined money was first introduced. It was to this prince that his court-fool related the celebrated fabulous conversation between the owl of Bassora and that of Mosul. Four of his sons, WALID I. (705—716), SULIMAN (716—717), YEZID II. (720—723), and HESHÂM (723—742), successively occupied the throne, and a fifth son, Moaslemah, was, from his great military abilities and zealous devotion to the interests of his brothers, the terror of all their enemies, both domestic and foreign. Under Walid, the Ommiade califate reached the summit of its power and grandeur; Northern Africa (709) and Spain (712), Turkestan (707), and Galatia (710) were conquered; while towards the close of his reign, his empire was extended even to the Indus. The slender structure of the minaret was now for the first time introduced into mosque architecture. OMAR II. (717—720), who, in the justice and mildness of his government, surpassed the whole of the race of Ommeyyah, was appointed to succeed Suliman; but having excited discontent among his relatives, by suppressing the formula of malediction, which had hitherto been regularly pronounced at all public ceremonies against Ali and his descendants, he was poisoned. During his reign, Moaslemah had completed the conquest of Asia Minor, and even compelled the Emperor Leo to submit to the humiliation of walking beside his horse through the principal streets of Constantinople itself, and paying a large ransom (equivalent to about £140,000) for his capital. Heshâm, though like his immediate predecessor, fond of pleasure, possessed all the qualities necessary for a sovereign. The Greeks, who still strove for the possession of Asia Minor, were repeatedly defeated: the fierce Turks of Northern Persia and Turkestan, were kept in stern subjection; and the civil affairs of the empire carefully and strictly administered. The death of Moaslemah, the champion of the Ommiade dynasty, seems to have been the signal for insurrection; the descendants of Ali raised the standard of revolt, and no sooner were they subdued than Ibrahim, the fourth in direct descent from Abbas the uncle of Mohammed, solemnly invested the celebrated Abu-Moslem (stated to be a descendant of Koderz, one of the most distinguished heroes of Firdusi's admired work the *Shah-namêh*) with the arduous duty of enforcing his long-agitated claims to the throne. During this reign the progress of Arab conquest in Western Europe was checked by Charles Martel, who inflicted upon the Arabs a severe defeat at Tours (732), and almost annihilated their army at Narbonne (736). The reigns of WALID II. (742—743), YEZID III. (743—744), and IBRAHIM (744), though of ephemeral duration, were long enough to produce a complete disorganisation of the empire; and though MERWÂN II. (744—750), the next and last calif of the house of Ommeyyah, was both an able and politic ruler, and a skilful warrior, the declining fortune of his family was beyond remedy. Abu-Moslem, who had published the claims of the Abbasides amidst the ruins of Meru in 747, took the field at the head of a small but zealous band, and carried the black flag of the Abbasides from victory to victory, till before the close of the following year the whole of Khorassan acknowledged his authority. Irak was subdued in 749; and though Ibrahim the Abbaside claimant was seized by Merwân, and executed in the same year, his brother Abul-Abbas succeeded to his claims, and the unfortunate calif, defeated in two engagements, fled to Egypt (750), whither he was pursued and slain. Abdallah, the uncle of the successful claimant, treacherously invited the remaining members of the house of Ommeyyah to a

conference, and ordered a general massacre of them. Two only escaped: the one to the south-east of Arabia, where he was recognised as calif, and his descendants reigned till the 16th century; the other, Abderrahman, to Spain, where he founded the califate of Cordova.

OMMIADES OF SPAIN.—ABDERRAHMAN I. (755—787), on accepting the Spanish throne which was offered him by the Arab chiefs, assumed the titles of *Calif* and *Emir-al-mumenin*, and in spite of numerous revolts, strengthened and extended his power in Spain, till, with the exception of Asturias and the country north of the Ebro, his authority was everywhere acknowledged. His defeat of Charlemagne at Roncevalles (q. v.) is too widely known to require further notice. He divided his kingdom into six provinces, whose rulers, with the *walis* of the twelve principal towns, formed a sort of national diet. His successors, HESHAM I. (787—796) and AL-HAKEM I. (796—821), were much troubled with internal revolts, under cover of which the Christians in the north-east established the state known as the 'Spanish March.' ABDERRAHMAN II. (821—852) re-established internal quiet, and occupied his subjects with incessant wars against the Christians. These conflicts developed among the Arabs that chivalrous heroism which is found nowhere else in the Mohammedan world. Abderrahman, himself a man of learning, greatly encouraged the arts and sciences, and diffused information among his people; he also attempted, by regulating the laws of succession to property, to constitute his kingdom on a basis analogous to that of other European nations. During his reign Mohammedan Spain was the best governed country in Europe. His successors, MOHAMMED I. (852—880), MONDHAR (880—882), and ABDALLAH (882—912), followed in his footsteps. ABDERRAHMAN III. (912—961), after suppressing some dangerous revolts which had gathered head during his minority, conquered the kingdom of Fez from the Edrisites, and brought a long and exhausting war with the powers of Asturias and Leon to a victorious conclusion. This period is justly termed the golden age of the Arab domination in Spain, for at no period was their power so consolidated, and their prosperity so flourishing. Abderrahman, like his predecessors, was a great encourager of learning, and a poet of no mean ability. He founded schools which far surpassed those in other parts of Europe. His son, AL-HAKEM II. (961—976), was in every way worthy to be his successor, but his premature death was the cause of the downfall of the Ommiades in Spain. HESHAM II. (976—about 1013), a child of eight years, now occupied the throne; but fortunately his mother, Sobeiha, possessed the abilities necessary for such an emergency, and appointed as her son's vizier Mohammed ben Abdallah, surnamed Al-Mansor, who had originally been a peasant. This remarkable man gained the affections of all ranks by his pleasing manners and great abilities; his administration was equally just and judicious, and his encouragement of literature, science, and art alike liberal and discriminating. But it is as a warrior that he is chiefly remembered; he had vowed eternal enmity to the Christians, and in all his numerous expeditions fortune seemed chained to his standard. The lost provinces were recovered; Castile, Leon, and Barcelona were conquered; and Navarre was on the point of sharing the same fate, when a rebellion in Fez compelled him to detach a portion of his force for service in Africa, and the combined armies of the four Christian monarchies, seizing this opportunity, inflicted upon the Arabs a sanguinary defeat in 1001. Mohammed's spirit was completely broken

by this blow, and he died a few days afterwards. With him the star of the house of Ommeyah set for ever. The rest of Hesham's reign was a scene of disorder and civil war. Pretenders to the califate arose, while the 'walis' of the various provinces set up as independent rulers, and the invasions of the Christians added to the confusion. Hesham finally resigned the throne about 1013; and, with the exception of the brief reign of HESHAM III. (1027—1031), from this time the family of Ommeyah, which had for more than two centuries so happily and brilliantly governed the greater part of Spain, disappears from history. One remarkable feature of their rule deserves mention, as it contrasts them so favourably with the contemporary and subsequent rulers of Spain, even to the present time, and that is their universal toleration in religious matters.

O'MNIBUS (Lat. *omnibus*, 'for all'), familiarly contracted into 'bus,' is the largest kind of public street conveyance, and is appointed to travel between two fixed stations, starting at certain fixed hours, and taking up or setting down passengers at any point in its route. Vehicles of this sort were first started in Paris in 1662, when it was decreed, by a royal edict of Louis XIV., that a line of *carrosses à cinq sous* ('twopence-halfpenny omnibuses'), each containing eight places, should be established for the benefit of the infirm, or those who, requiring speedy conveyance from one part of the town to another, were unable to afford a hired carriage for themselves; these 'carrosses' were bound to run at fixed hours from one station to another, whether full or empty. The public inauguration of the new conveyances took place March 18, 1662, and was the occasion of a grand fête; and the novelty took so well with the Parisians, that the omnibuses were for some time monopolised by the wealthier classes. However, when the rage for them died away, it was found that those for whose special benefit they were instituted made no use of them, and they, in consequence, gradually disappeared. The omnibus was not revived in Paris till 1827, when it was started in its present form, carrying from 15 to 18 passengers inside, with only the driver above and the conductor behind; and on July 4, 1829, they were introduced into London by a Mr Shillibeer. Shillibeer's conveyances, which for some time afterwards were known as *shillibeers* (an epithet long in common use in New York), were of larger size than the French ones, carrying 22 passengers inside, and were drawn by three horses abreast. The omnibus was introduced into Amsterdam in 1839, and since that time its use has been extended to all large cities and towns in the civilised world. The seats of the omnibus are generally placed lengthwise, and the door behind. The omnibus is managed by a driver and a conductor. In New York, omnibuses are drawn on street-railways; and this practice is now being extensively employed in the chief towns of Great Britain, where the omnibuses are called tramway cars, and the railway a tramway.

O'MNIUM, a term used at the Stock Exchange to express the aggregate value of the different stocks in which a loan is funded. See M'Culloch's *Dictionary of Commerce*.

OMSK, a town of the Russian province of Central Asia, in the government of Akmolinsk, stands at the confluence of the Om—a river upwards of 200 miles in length—with the Irtysh; 2225 miles from St Petersburg. Lat. 54° 59' N., long. 73° 30' E. It was built in 1716, as a defence against the Khirghiz; but is now of no importance as a fortress. It was till a recent date the centre of government for Western Siberia, the centre of the administration of the Siberian Khirghiz, the seat of

the courts of justice, and of the Siberian corps of cadets. It contains manufactories and mining works. Hitherto its commerce has been limited to a trade with the Khirghiz, who drive up their cattle to this place; but its advantageous position on the great post-road and commercial line of traffic from Europe across the whole of Siberia to the Chinese frontier, makes it probable that it will some day become an intermediate station for extensive commercial exchanges. Pop. (1880) 30,890.

OMUL (*Salmo migratorius*), a fish of the salmon and trout tribe, abounding in Lake Baikal and other waters of the east of Siberia, from which great quantities are sent salted to all the western parts of that country. In size it is rarely more than 15 or 16 inches long. Its flesh is very white and tender. It ascends rivers in shoals for the purpose of spawning.

O'NAGER. See **ASS**.

ONAGER. See **BALISTA**.

ONAGRA'CEÆ, ONAGRARIÆ, or (ENO-)THERA'CEÆ, a natural order of exogenous plants, consisting chiefly of herbaceous plants, but including also a few shrubs; with simple leaves; axillary or terminal flowers; the calyx superior, tubular, sometimes coloured, its limb usually 4-lobed; the petals inserted into the throat of the calyx, generally equal in number to its segments; the stamens generally four or eight, rarely one or two, inserted along with the petals; the ovary generally 4-celled, sometimes 2-celled; the style threadlike, the fruit a capsule or a berry. There are about 450 known species, natives chiefly of temperate climates, among which are some much cultivated for the beauty of their flowers, particularly those of the genera *Fuchsia*, *Enothera* (Evening Primrose), *Clarkia*, and *Godetia*. The British genera are *Epilobium* (Willow-herb) and *Circea* (Enchanter's Nightshade). A few species produce edible berries, and the roots of one or two are eatable; but none are of economical importance. The root of *Isomada alternifolia*, found in the marshes of Carolina, and called *Bowman's Root*, is emetic. Some species of *Jussiaea* are used in dyeing in Brazil.

ONCOCARPUS, a genus of trees of the natural order *Anacardiaceæ*. One of the most remarkable trees of the Fiji Islands is *O. atra*, or *O. vitiensis*, a tree about sixty feet high, with large oblong leaves and a corky fruit, somewhat resembling the seed of a walnut; the sap of which, if it comes into contact with the skin, produces a pain like that caused by red-hot iron. The wood is often called Itch-wood, because of the effect produced on persons who ignorantly or incautiously bark it whilst the sap is fresh, even the exhalations causing an intolerable itching and innumerable pustules, with excessive irritation for several days, whilst the effects continue to be unpleasantly felt even for months.

ONEGA, a small town and seaport in the north of Russia, in the government of Archangel, and 90 miles south-west of the city of that name. It stands at the mouth of a river, and on the shore of a gulf of the same name; the latter a branch of the White Sea. Lat. 63° 54' N., long. 38° 7' E. Pop. (1877) 2309, employed in connection with the saw-mills of the 'Onega Trading Wood Company.' In these mills, where numerous men are at work, an English steam-engine has been erected. About 50 ships leave the port annually for England, with cargoes of deals and timber to the value of £37,000.

ONEGA, LAKE, an extensive lake in the north of Russia, government of Olonetz, and, after Ladoga, the largest lake in Europe, is 59 miles in greatest

breadth, and about 150 miles in length. Area, 3720 square miles. It is fed by numerous rivers, and receives through the river Wodlo the waters of the lake of that name. Its only outlet is the river Swir, which flows south-west into Lake Ladoga. By means of the Mariinsky system of communication, Lake O. communicates with the Volga, and thence with the Caspian Sea on the south, and with the Dwina, and thence with the White Sea on the north. The clear and beautiful waters of this lake are rich in fish, and embrace many islands. The depth ranges from 550 to 700 feet. The navigation of the lake is dangerous, and is avoided by means of the Onega Canal, which extends from Vytegra on the Vytegra River to the river Swir.

ONEIDA. See **PERFECTIONISTS** in SUPP., Vol. X.

O'NEROUS CAUSE, in Scotch Law, means a pecuniary or valuable consideration.

ONION (Fr. *oignon*, from Lat. *unio*, a pearl, but found in Columella, signifying a kind of onion), the name given to a few species of the genus *Allium* (q. v.), and particularly to *A. cepa* (Lat. *cepa*), a biennial bulbous-rooted plant, with a swelling stem, leafy at the base, tapering fistular leaves, a reflexed spathe, a large globose umbel, usually not bulbiferous, the lobes of the perianth obtuse and hooded, not half as long as the stamens. The bulb is simple—not composed of cloves, like that of garlic; and in the common variety is solitary, shewing little tendency to produce lateral bulbs. The native country of the O. is not certainly known, some supposing it to be India and some Egypt, in both of which it has been cultivated from the most remote antiquity. The part chiefly used is the bulb, but the young leaves are also used, and young seedlings drawn from onion beds are a very common ingredient in soups and sauces in the beginning of summer. These are known in Scotland as *syboes* (evidently another form of the word *Cibol*). In warmer climates, the O. produces a larger bulb, and generally of more delicate flavour, than in Britain; and is more extensively used as an article of food, being with us, whether fresh or pickled, generally rather a condiment. In Spain and Portugal, a raw O. is often eaten like an apple, and often with a piece of bread forms the dinner of a working-man. The O. is, however, very nutritious. It contains a large quantity of nitrogenous matter, and of uncrystallisable sugar; with an acrid volatile sulphurous oil, resembling oil of garlic. The oil of the O. is dissipated by boiling, so that boiled onions are much milder than raw onions. In Britain, onions are sown either in spring or in August. Great fields of them, as of other favourite vegetables, are cultivated for the London market; and large quantities of onions are also imported from more southern regions. The Bermudas are celebrated for their onions. The O. loves a rich light soil and a dry subsoil. The transplanting of onions is often practised, especially of onions sown in autumn, which are transplanted in spring, and when these are placed so that the small bulbs are on the surface of the ground, and surrounded with decayed manure, very large bulbs are obtained. The frequent stirring of the soil is of great advantage. The bulbs are taken up when the leaves decay, and after being dried in the open air or in a loft, may be kept for a considerable time.—The **POTATO O.**, also called the **EGYPTIAN** or **GROUND O.**, is a perennial variety which produces offset bulbs at the root, like the shallot; but the bulbs are much larger than those of the shallot, and have less of the flavour of garlic, although stronger than those of the common onion. It is sometimes said to have been introduced into Britain from

Egypt by the British army in 1805, but erroneously, as it was cultivated in some parts of Britain long before. It is in very general cultivation among the peasantry in some parts of Scotland.—The PEARL O. is a similar variety, with much smaller bulbs.—The TREE O. is also generally regarded as a variety of the common onion. It produces bulbs at the top of the stem, the umbels becoming viviparous.—Onions are similar to Garlic (q. v.) in medicinal properties, but milder. As a condiment or article of food, they agree well with some stomachs and stimulate digestion, but are intolerable to others. Roasted onions with oil make a useful emollient and stimulating poultice for suppurating tumours. The use of onions stimulates the secreting organs.—The CIBOL or WELSH O. (*A. fistulosum*), a native of Siberia, cultivated in Britain, but more generally in Germany, has a perennial fibrous root, with no bulb, very fistular leaves, and a 3-cornered ovary. It is useful as supplying tender green leaves for culinary use in the beginning of spring, like the chive, and somewhat earlier in the season. It is much larger than the chive, but its use is similar.

ONISCUS. See WOODLOUSE.

O'NKELOS, the supposed author of an Aramaic version (Targum) of the Pentateuch. The name seems a corruption from that of Akilas, one of the Greek translators of the Old Testament (see AQUILA). The translation, said to be by O., is, in its present shape at least, probably the work of the Babylonian schools of the 3d and 4th centuries A.D. At first orally transmitted, various portions of it began to be collected and written down in the 2d c., and were finally redacted about the time mentioned. The history of the origin and growth of Aramaic versions in general will be treated under *Targum* (VERSIONS). The idiom of O. closely resembles that of Ezra and Daniel. The translation itself is executed in accordance with a sober and clear, though not a slavish exegesis, and keeps closely to its text in most instances. In some cases, however, where the meaning is not clear, it expands into a brief explanation or paraphrase, uniting the latter sometimes with Haggadic by-work, chosen with tact and taste, so as to please the people and not to offend the dignity of the subject. Not unfrequently it differs entirely from the original, as far, e. g., as anthropomorphisms and anthropopathies—anything, in fact, which might seem derogatory to the Deity—are concerned. Further may be noticed a repugnance to bring the Divine Being into too close contact, as it were, with man, by the interposition of a kind of spiritual barrier (the 'Word,' 'Shechinah,' 'Glory') when a conversation, or the like, is reported between God and man. Its use lies partly in a linguistic, partly in a theological direction; but little has been done for its study as yet. Notwithstanding the numerous MSS. of it extant in almost all the larger libraries of Europe, and in spite of the grossly incorrect state of our current printed editions, no critical edition has ever been attempted.

ONOBRYCHIS. See SAINTFOIN.

ONOMACRITUS, a celebrated religious poet of ancient Greece, lived at Athens in the time of the Peisistratidæ. He collected and expounded—according to Herodotus—the prophecies or oracles of Musesus (q. v.), but is said to have been banished from the city by Hipparchus, about 516 B.C., on account of interpolating something of his own in these oracles. He then, we are told, followed the Peisistratidæ into Persia, and while there was employed by them in a very dishonourable way. They got him to repeat to Xerxes all the ancient sayings that seemed to favour his meditated

invasion of Greece. Some critics, among whom is Aristotle, have inferred from a passage in Pausanias that O. is the author of most of the so-called Orphic hymns. More certain, however, is the view which represents him as the inventor of the great Orphic myth of Dionysus Zagreus, and the founder of Orphic religious societies and theology. Pausanias states that 'Onomacritus established orgies in honour of Dionysus, and in his poems represented the Titans as the authors of the sufferings of Dionysus.' See the article ORPHEUS in this work; the standard histories of Greece (as Grote's) and of Greek literature (as Mahaffy's).

ONOMATOPŒIA, the Latin form of the Greek word *onomatopoiia* means literally the making or invention of names, and is used in philology to denote the formation of words in imitation of natural sounds, as in *cuckoo*, Lat. *cucu(lus)*; *pee-wee*, Scan. *pee-weip*, Dutch, *kiewit*; *cock*; *clash*, *rap*, *tap*, *quack*, *rumble*, *whizz*, *clang*. Such words are sometimes called *onomatopœias*; more properly, they are *onomatopœian*, or formed by *onomatopœia*.

In a more extended sense, the term is applied to the rhetorical artifices by which writers (chiefly poets) seek, through the choice and arrangement of words, to make the 'sound,' throughout whole phrases and sentences, 'an echo to the sense,' as in Homer's well-known *poluphloioio thalasses*, expressive of the breaking of waves upon the seashore; or where Tennyson makes the sea

Roar rock-thwarted under bellowing caves.

The occurrence of so many obviously onomatopœian words in all known languages, suggests the question, whether the same principle may not have been concerned in producing the original germs or roots of the great bulk of words. There is little hope that the question will ever be conclusively settled either way; for the changes of time have made it, in most cases at least, impossible to say what the first form and signification of a root were; but the balance of arguments seems in favour of the affirmative answer. 'The action of the mind,' as it has been expressed, 'produced language by a spontaneous repercussion of the impressions received.' Now, the articulate sound first affixed in this way to an object or an action as its sign cannot be conceived as arbitrary; nor is there any mysterious and inherent correspondence between any one conception of the mind, and a particular articulate sound. The sound uttered must have been suggested by something connected with the object or action itself; and by what more naturally than by the inarticulate sound which the object or action itself emits?

The chief objection to this theory is, that if the first words were merely reproductions of natural sounds, the same natural objects would have had the same names all the world over. To which it is answered, that the mind in its first efforts at naming did not seek an exact reproduction of the sound, but a suggestive imitation; primitive words were not echoes, but 'artistic representations.' Now, the sounds of nature are not simple, but composite. Like other concrete phenomena, they present a variety of aspects; and according as one or another aspect seemed the most prominent to the observer, a different vocal sound would suggest itself as the appropriate symbol. Thus, when Professor Max Müller argues (*Science of Language*, Lond. 1861) that if the 'bow-wow' theory, as he nicknames it, were true, men would have everywhere spoken of a *moo*, as is done in the nursery, and not of a *cow*; it seems a valid answer to say, that the Indian *gu*, the Teut. *kuh* (Eng. *cow*), and the Græco-Lat. *bou*, are really as suggestive imitations of the animal's

actual voice as *moo*. To take a more striking instance: few words differ more in sound and aspect than the Eng. *thunder* (Ger. *donner*, Lat. *tonitru*, Fr. *tonnerre*) does from the Mexican name for the same thing, *tlallatimil*, and yet it would be difficult to say which is the more suggestive of the natural sound.

It is no doubt true that the great bulk of names are derived from roots having a general predicative power; but this by no means excludes the principle of onomatopœia. Thus, to take one of the instances adduced by Professor Müller himself, that of *raven* or *crow* (Sana. *kárava*, Lat. *corvus*, Gr. *korónē*); this is derived from the root *ru* or *kru*, which means to cry or call, and the bird was called a *kárava*, or *crow*, not in imitation of his voice, but because he was 'a shouter, a caller, a crier. The name might have been applied to many birds, but it became the traditional and recognised name of the crow.' But how came the articulation *ru* or *kru* to be chosen to convey the general meaning of crying or calling; may we not suppose that it was suggested by the voice of birds of the crow kind, whose notes are most markedly cries or calls to their fellows, as distinguished from singing? Once adopted in this particular case, it would naturally be extended to any kind of cry or call, from the harshest to the softest.

ONTARIO, the easternmost and smallest of the five great lakes of North America, lies in 43° 10'—44° 8' N. lat., and 76° 30'—80° W. long. At its south-west corner it receives the waters of the upper lakes by the Niagara, and at its north-east corner it issues into the St Lawrence; which for some distance below is called the Lake of the Thousand Isles. Its surface, which varies a few feet with the seasons, is about 330 feet below that of Lake Erie and 234 feet above tide-water. Its bottom, therefore, must be considerably lower than the level of the Atlantic, as it is in some places 600 feet deep. It is 190 miles long, 55 in its widest part, and about 480 in circumference. Sufficiently deep throughout for vessels of the largest tonnage, it has many convenient and thriving ports, of which the chief are Kingston, Port Hope, Cobourg, Toronto, Hamilton, on the Canadian shore, and Oswego, Sackett's Harbour, Port Genesee in the United States. Its navigation has been facilitated by the erection of 15 light-houses on the American side, and 13 on the Canadian; while it is connected with Lake Erie by the Welland Canal, with the Erie Canal and New York by the Oswego Canal, and by the Rideau Canal with the Ottawa. Lake O. is subject to violent storms, and it is probably owing chiefly to the constant agitation of its waters that it freezes only for a few miles from the shore. The shores of Lake O. are generally very flat, but the Bay of Quinte, a long crooked arm of the lake, which stretches about 50 m., possesses some attractive scenery. Burlington Bay, on which Hamilton lies, is a large basin, almost inclosed by a natural, but strangely accumulated bank of sand, which forms a beautiful drive.

ONTARIO, the province. See CANADA.

ONTO'LOGY. See METAPHYSICS.

O'NUS PROBANDI, i. e., the burden of proof, is often a difficult question in litigation; but as a general rule, the plaintiff who institutes the suit is bound to give proof of the allegations on which he relies. There are many nice and technical rules on the subject, both in suits and actions, which are too minute to be here stated.

O'NYX, an agate formed of alternating white and black, or white and dark-brown stripes of chalcedony. More rarely, a third colour of stripes occurs. The finest specimens are brought from

India. O. is in much esteem for ornamental purposes. The ancients valued it very highly, and used it much for cameos. Many of the finest cameos in existence are of onyx. The name O., however, appears to have been applied by the ancients more extensively than it now is, and even to striped calcareous alabaster, such as is now called Onyx Marble. The *Sardonys* of the ancients is a variety of O., in which white stripes alternate with stripes of a dark-red variety of carnelian, called *sard* or *sarda*. It is one of the rarest and most beautiful kinds of O., and is more valued than carnelian.

ONYX MARBLE, a very beautiful material, which first came into general notice in this country at the Exhibition of 1862. It is a stalagmitic formation, which was discovered by the French in making roads in the province of Oran in Algiers. It is a translucent limestone, containing traces of magnesia and carbonate of iron; its specific gravity is 2.780. Of it artistic workmen of France manufacture very beautiful ornamental works.

OODEYPUR. See ODEYPOOR.

OJJE'N. See UJEIN.

OOLACHAN. See CANDLE-FISH in SUPP., Vol. X.

O'OLITE (Gr. egg-stone), a variety of limestone, often very pure calcareous spar, distinguished by its peculiar structure, being composed of grains connected together by a calcareous cement; the whole much resembling the roe of a fish. The grains are not unfrequently hollow. Many oolites, as in the south of England, are excellent building-stones. There is no important mineralogical difference between O. and *Pisolite*, or *Pea-stone*. O., as a geological term, is extended far beyond its mineralogical and original signification.

OOLITE or JURASSIC GROUP (in Geology), an extensive and important series of strata of Secondary age, underlying the Chalk formation, and resting on the Trias. In Britain they received the name Oolite, because in the district where they were first examined and described by Dr W. Smith, the limestones contained in them had an oolitic structure (see foregoing article). The name Jurassic has been given to them on the continent, because the range of the Jura Mountains in the north-west of Switzerland is almost entirely composed of them. The strata of the group have been arranged in the following order. The maximum thickness of each division is given in feet:

UPPER OOLITE.		Feet.
1. Purbeck Beds,		200
2. Portland Beds,		170
3. Kimmeridge Clay,		600
		— 970
MIDDLE OOLITE.		
4. Coral Rag,		100
5. Oxford Clay,		600
		— 700
LOWER OOLITE.		
6. Cornbrash and Forest Marble,		80
7. Great Oolite and Stonesfield Slate,		150
8. Fuller's Earth,		150
9. Inferior Oolite,		250
		— 630
LIAS.		
10. Upper Lias,		300
11. Marlstone,		200
12. Lower Lias,		600
		— 1100
Total,		3490

It is apparent from this table that the Oolitic rocks consist of three extensive clay deposits, each of which forms the basis of a smaller and variable set of sands and limestones; the Upper

Oolites resting on the Kimmeridge Clay, the Coral Rag on the Oxford Clay, and the Lower Oolite on the Lias.

1. The Purbeck beds, unlike the other oolitic rocks, are chiefly freshwater deposits. Though lithologically they are very similar throughout, the peculiarities of the contained fossils have caused them to be grouped into three series—the Upper, Middle, and Lower. The Upper Purbecks are purely freshwater, containing beds of limestone and shale, which abound in shells of lake and river mollusca and cyprides. The stone called Purbeck Marble, formerly so extensively used in the ornamental architecture of English churches and other buildings, belongs to this division; it consists of the shells of *Paludina*, held together by a somewhat argillaceous paste. The Middle Purbecks are partly freshwater, and partly brackish or marine. The 'cinder-bed,' composed of a vast accumulation of shells of *Ostrea distorta*, occurs in this section, and near it is the narrow layer from which Mr Beekes recently obtained the remains of several mammalia. The Lower Purbecks are chiefly freshwater, with some intercalated brackish or marine beds, and one or two old vegetable soils called by the quarrymen 'dirt-beds,' which contain the stems of Cycadaceous and Coniferous plants. 2. The Portland beds consist of oolitic and other limestones interstratified with clays, and passing below into sands and sandstones, from which the well-known building-stone is obtained, of which St Paul's and many of the principal buildings in London are built. 3. The Kimmeridge Clay is generally a dark-gray bituminous shale, with intercalated beds of sand, calcareous grit, and layers of septaria. The dark shale in some places passes into an impure brown shaly coal. 4. The Coral Rag contains, as its name implies, an abundance of corals, in bluish limestone beds mixed with layers of calcareous grit. The Solenhofen lithographic stone, with its beautifully preserved and varied fossil remains, belongs to this division. 5. The Oxford Clay is a dark-blue or blackish clay without corals, but having a large number of beautifully preserved Ammonites and Belemnites. Beds of calcareous sandstone, called Kelloway Rock, occur in its lower portion. 6. The Cornbrash consists of thin beds of cream-coloured limestone, with sandstones and clays, and the Forest Marble (so named from Wychwood Forest) is composed of an argillaceous limestone, with numerous marine fossils, blue marls and shales, and yellow silicious sand. At Bradford, Wiltshire, the Forest Marble is replaced by a considerable thickness of blue unctuous clay. 7. The Great Oolite is composed of shelly limestones, sandstones, and shelly calcareous sandstones, and the Stonesfield Slate is a slightly oolitic shelly limestone, which splits into very thin slabs, erroneously called 'slates;' it is remarkable for the remains of terrestrial reptiles and mammals found in it. The Bath Oolite, a celebrated building-stone, belongs to this division. 8. The Fuller's Earth group is a local deposit found near Bath; it consists of a series of blue and yellow shales and marls, some of which have properties fitting them for the use of the fuller. 9. The Inferior Oolite is composed of a series of beds of pisolitic and shelly limestones, brown marl, and brown sandy limestone, all abounding in fossils. 10. The Lias (q. v.) is a great clay deposit. It is divided into the Upper and Lower Lias, which consist of thin beds of limestone scattered through a great thickness of blue clay, and, separating these two groups, the Marlstone, or calcareous or ferruginous sandstone. The lias abounds in beautifully preserved fossils.

The oolite occupies, in England, a zone nearly

thirty miles in breadth, extending across the country from Yorkshire to Dorsetshire. In Scotland, patches of lias and Oxford clay occur in the islands of Mull and Skye, and on the western shores of the mainland, and beds belonging to the lower oolite are found at Brora, on the east coast of Sutherland, which contain an impure coal. The only oolite rocks in Ireland are a few isolated patches in Antrim, which abound with the fossils of the lower lias. On the continent, rocks of this age occur in Germany and France, but they have been most extensively studied in the Jura Mountains, which, though having a height of 6000 feet, are entirely composed of oolite and cretaceous rocks. The strata are greatly bent and contorted, and as they approach the Swiss Alps, the great mass of which is also formed of oolite, they become completely metamorphosed into clay slates, mica schists, gneiss, and crystalline limestones. Beds of oolite have been noticed in Cutch, in India. In Australia similar beds occur on the western coast, and probably some of the coal-beds of New South Wales, Victoria, and Tasmania belong to the oolite. In both North and South America, fossils, apparently of oolitic age, have been found; but these deposits require to be more exactly examined.

The oolite is remarkable for the abundance of its fossils, and is in this respect in striking contrast to the immediately preceding Triassic and Permian periods. The several freshwater deposits, and the ancient vegetable surfaces, contain the remains of a considerable number of plants. Ferns still abound, and with them are associated species that are evidently related to the living genera *Cupressus*, *Aracaria*, and *Zamia*.

Corals abound in several of the beds. The brachiopods are the only division of the mollusca that is not largely represented. The conchifers and gasteropods shew a great number and variety of new genera, which are nearer the forms of the present day than those that preceded them. But the remarkable feature of molluscan life is the enormous development of the cephalopods. Whole beds are almost entirely made up of their shells. No less than 600 species of ammonites have been described, chiefly from the rocks of this period, and the belemnites were also very numerous. The crinoids have become scarce, but are replaced by star-fishes and sea-urchins. The freshwater beds contain the remains of many insect forms. The heterocercal-tailed fish give way to the more modern homocercals, and the true sharks and rays make their appearance, though the old cestracions are still represented by some survivors. The characteristic feature of the oolitic period was its reptiles. The land, the sea, and the air had each their fitting inhabitants of this class. The various species of pterodactyles, some not larger than the bat, others surpassing, in the stretch of their membranous 'wing,' the size of the largest living bird, were the terrors of the air; while their allies, the monster ichthyosaurs and plesiosaurs, held the mastery of the waters; and the huge megalosaurus, some not less than 30 feet in length, trod the earth. The few mammalian remains hitherto found, have a special interest from their antiquity, being the first evidence of this high order of animals on the globe. They belong, apparently, to marsupial animals; one species is, however, supposed by Owen to have been a hoofed and herbivorous placental mammal.

OONALA'SKA. See UNALASHKA.

OORALSK. See URALSK.

OORALI. See WOORALI.

OORFA, OORGA. See URFA, URGU.

OORI or LIMPOPO RIVER, an important river system of South-Eastern Africa, rising in lat. 26° S. in the high plateau called the Magaliesberg, which forms the northern limit of the basin of the Orange River. Throughout a great part of its course, the Limpopo bounds on the north the Transvaal territory which its southern affluents drain. It flows in a north-easterly direction through the plateau in which it rises, then turns sharply to the south-east and south, when it enters the lowlands. It reaches the Indian Ocean about 100 miles north of Delagoa—considerably further south than was till recently believed. Its course cannot be less than 800 or 900 miles long, and it has numerous large tributaries, the Mariqua, Lipalula, &c. Yet, like most South African rivers, it is navigable only 60 miles from its mouth, which is blocked by a double bar.

OOROMEYAH. See **URUMEYAH.**

OO'STERHOUT, a Dutch town in North Brabant. Pop. (1879) 9853, almost all Catholics. Much business is done in grain and cattle. There are tanneries, beer-breweries, potteries, and brick-works.

OOTACAMUND (*Utakamand*), the chief town in the Neilgherry Hills, the great sanatorium of the Madras presidency, and the summer headquarters of the governor of Madras. It stands on a plateau, in an amphitheatre surrounded by noble hills, and is 7228 feet above the sea; the mean temperature being about 49°, the maximum 76°, and the minimum 38°. The average rainfall is 45 inches. Its distance is only about 350 miles from Madras, and it is easy of access, as the railway now conveys the traveller to the foot of the Hills. There are thriving plantations of tea and coffee, and the cinchona or quinine plant. Pop. about 10,000. The first house was built in 1821.

OOZE. Limestone is mostly of animal origin, though often much altered. Chalk is manifestly so. It often contains embedded in it shells and other animal remains visible to the naked eye, showing it must have been deposited in the sea. The grains that form the mass of chalk, when examined under the microscope, are found to be the shells, broken or entire, of foraminifera. Myriads of these creatures people at this day the waters of the Atlantic near the surface, and as they die, their shells sink down in an incessant drizzle, adding year by year to the thickness of the gray ooze that covers great areas of the sea-bottom. Under the microscope, particles of this ooze exactly resemble particles of chalk. Mixed up with the calcareous remains in the ooze there is a quantity of silica consisting of the remains of organisms that secrete silicious coverings and skeletons. This accounts for the flint nodules in chalk, and the concretions of quartz in limestone.

O'PAH, or KING-FISH (*Lampris guttatus* or *L. luna*), a fish of the Dory (q. v.) family (*Zetidae*), occasionally found in the British seas, but more common in more northern regions, and found not only in the Atlantic and Arctic Oceans, but also in the Pacific, as on the coasts of China and Japan. It is of an oval form, greatly compressed, with small thin scales, the mouth small and destitute of teeth, a single dorsal fin much elevated in front and extending almost to the tail. This fish attains a large size, being sometimes five feet long and 150 pounds in weight. It is brilliantly coloured; the upper part of the back and sides rich green, reflecting purple and gold in different lights, the lower parts yellowish-green, round yellowish-white spots above and below the lateral line; all the fins bright vermilion. The flesh is much esteemed; it is red like salmon, and is said to resemble it in flavour.

O'PAL, a mineral which differs from quartz in containing from 5 to 13 per cent. of water, its only other essential constituent being silica, although a little alumina, oxide of iron, &c., is often present. It is never found crystallised, and does not exhibit a crystalline structure like quartz. It has a conchoidal fracture, and is very easily broken. There are many varieties, which pass into one another, so that their precise limits cannot be defined, from which has arisen no little confusion of names. The finest kind is called *Precious O.* or *Noble O.*, and sometimes *Oriental Opal*. It is semitransparent or translucent, usually of a bluish or yellowish white colour, yellow by transmitted light, and exhibits a beautiful play of brilliant colours, owing to minute fissures which refract the light. It is much valued for setting in rings, brooches, &c., and is polished with a convex surface, never cut into facets, both because of its brittleness, and because its play of colours is thus best exhibited. The ancients valued opals very highly. The Roman senator Nonius preferred exile to giving up an O. to Mark Antony. This O. was still to be seen in the days of Pliny, who ascribes to it a value equal to more than £100,000 sterling. The imperial cabinet of Vienna contains the most celebrated O. now known to exist. It is five inches by two inches and a half. The finest opals are almost all brought from Kaschan in Hungary, where they are found disseminated in a trachytic conglomerate. They are mostly very small, but even a very small O., if really beautiful, is worth four or five pounds; and the price increases very rapidly with increase of size. *Precious O.* is found also in Saxony, in South America, &c. When the colours are not equally diffused, but in detached spots, jewellers call it *Harlequin Opal*. There is a dark or blackish variety, apparently tinged by oxide of iron, which occasionally exhibits very beautiful reflections, and is then much prized. *Girasol* (q. v.) and *Cacholong* (q. v.) are varieties of opal. What lapidaries call *Prime d'Opal* is clay-porphry, or other stone containing many small grains of opal. It is cut into slabs, and made into boxes and other ornamental articles; the stone which contains the opals being often artificially blackened by boiling in oil, and afterwards exposing to a moderate heat.—*Common O.* is semitransparent, white, yellow, green, red, or brown, and does not exhibit any play of colours. It is not a rare mineral, and is chiefly found in clay-porphry. *Semi-opal* is more opaque. *Wood O.* is a petrification, and exhibits the form and structure of wood, the place of which has been taken by the siliceous mineral. *Hyalite* and *Menilite* are varieties of opal.

OPEN-BILL (*Anastomus*), a genus of birds of the Heron family (*Ardeide*), natives of the East Indies and of Africa, remarkable for the structure of the bill, the mandibles being in contact only at the base and tip, with a wide interval between their edges in the middle. They frequent the sea-coast and rivers, and prey on fish and reptiles. One species is well known in India as the Coromandel Heron.

OPEN DOORS, LETTERS OF, in Scotch Law, mean a writ authorising a messenger to poind or seize goods deposited in lockfast-places, and to break open the locked doors in order to effect the seizure. See **HOUSE**.

OPERA, a musical drama, in which music forms an essential part, and not a mere accessory accompaniment. As in the higher drama, poetry supercedes the prose of ordinary life, so in the opera, with perhaps as great artistic right, the language of music is introduced at a considerable sacrifice of probability. The libretto or words are, in the

modern opera, a peg on which to hang the music, rather than the music an accessory to the written drama. The component parts of an opera are recitatives, duets, trios, quartets, choruses, and finales, accompanied throughout by an orchestra, and the whole is preceded by an instrumental Overture (q. v.). Recitative is declamation, which, in its succession of musical sounds and rhythm, strives to assimilate itself as much as possible to the accents of speech, and therefore does not entirely conform to musical rhythm. The accessories of scenic representation are also present, and a Ballet (q. v.) is also frequently introduced. In some of the German operas, and in the French *opéra comique*, spoken dialogue without music takes the place of recitative. Among the different varieties of the opera enumerated are the great opera or *opéra seria*, of a dignified character; the romantic opera, embracing an admixture of the grave and lively; the comic opera, or *opéra buffa*; as well as many intermediate varieties.

The idea of the opera may in part have arisen from the Greek drama, which possessed, to a considerable extent, the operatic character: the choral parts were sung, and the dialogue was delivered in a sustained key, probably resembling operatic recitative more than ordinary speech. The earliest extant example of any composition resembling the lyric drama of the moderns is Adam de la Halle's comic opera of *Li gieu (le jeu) de Robin et de Marian*, composed in the 13th c., the music of which is wonderful for its date. The next appearance of anything like opera is in the 16th century, when various musical dramas were composed in the madrigalesque style. An opera composed by Zarino is said to have been performed at Venice when Henry III. passed through that city on his way from Poland to France. About the same time, a pastoral called *Dafne*, written by the poet Rinucci, was set to music by Peri; and the same poet and musician conjointly produced the lyric tragedy of *La Morte di Euridice*, which was represented at the theatre of Florence in 1600. Claudio Monteverde, one of a society of amateurs, known as the 'Florentine Academy,' who devoted themselves avowedly to the study and revival of Greek music, soon afterwards produced his *Orfeo*, a 'favola di musica,' in whose performance an orchestra of no fewer than 36 performers was called into requisition, most of the instruments being, however, only used in twos or threes, and never more than ten at a time. From these beginnings, the opera advanced into one of the permanent institutions of Italy—a development of music at first strongly opposed in character and style to the music of the church. With the progress of music, and the perfecting of the musical instruments which went to form the orchestra, the lyric drama began, towards the middle of last century, to approach its present character. Of the innumerable Italian operas of last century, only Cimarosa's *Matrimonio Segreto* retains its place on the stage. Cherubini, the first of the more modern school, after producing his *Quinto Fabio* at Milan, became naturalised in France: Rossini, who succeeded him in Italy, is the greatest name in the Italian opera. Nothing can exceed the deliciously fresh character of the best known operas of this truly great musician, *Il Barbiere di Siviglia*, *Otello*, *La Gazza Ladra*, *Semiramide*, and *Guillaume Tell*. Next to them rank the equally well-known works of Bellini, *Norma*, *La Sonnambula*, and *I Puritani*; *Lucia di Lammermoor*, *Lucrezia Borgia*, and *L'Elisir d'Amore*, the three *chefs-d'œuvre* of Donizetti, alone rivalling them in public estimation. A newer school of opera has recently sprung up in Italy, more grand if less fresh, of which the chief

master is Verdi, whose *Ernani*, *Nabuchodonosor*, *I Lombardi*, *Otello*, *Rigoletto*, *Il Trovatore*, *La Traviata*, and others have attained immense popularity in Italy, and wherever the Italian opera has been naturalised.

From Italy the opera was introduced into Germany, where, more scientific and less sensuous than in Italy, it flourished in opposition to national as well as ecclesiastical music. Germany divides with Italy the honour of perfecting orchestral music and the opera. Glück, educated in Italy, produced his *Orfeo* in Vienna, and then went to Paris, where the French adopted him as we did Handel. Mozart was the first composer of operas for the modern orchestra; *Idomeneo*, *Il Seraglio*, *Le Nozze di Figaro*, *Don Giovanni*, and *Zauberflöte* are his principal operatic works, unsurpassed by anything that has succeeded them. The most important German operas composed since their date are *Fidelio* by Beethoven; *Der Freischütz*, *Euryanthe*, and *Oberon* by Weber; *Faust* by Spohr; and the gorgeous operas of Meyerbeer, *Robert le Diable*, *Les Huguenots*, and *Le Prophète*, and *L'Étoile du Nord*. *Les Huguenots*, notwithstanding its involving enormous difficulties in representation, keeps its place in every operatic theatre in Europe. Wagner, the chief exponent of a more recent school, generally known as that of the 'music of the future,' has by his *Tannhäuser*, *Lohengrin*, *Parsifal*, and other operas, found favour in Germany, and become well known in England. See the articles GLÜCK, WAGNER, &c.

In France, the earliest operatic representation of which we have any record was in 1682. About 1669, the Abbot Perrin obtained from Louis XIV. the privilege of establishing an opera in the French language at Paris, and in 1672 the privilege was transferred to Lulli, who may be considered the founder of the French lyrical drama. Lulli's popularity continued during a long period, and was only put an end to by the rise of the German Glück, who, naturalised in Paris, produced there his *Iphigénie en Aulide* and *Alceste*. It is greatly through Glück's influence that the modern French opera has become what it is, a composite work combining French, German, and Italian elements. Its best-known productions include Méhul's *Joseph*, Halévy's *Juive*, Auber's *Masaniello*, *Fra Diavolo*, and *Diamant de la Couronne*, and Gounod's *Faust*, *Polyeucte*, and *Tribut de Zamora*. The Italian opera, introduced in Paris in 1646 by Cardinal Mazarin, and superseded in 1670, was revived in the beginning of the present century, and has since flourished side by side with the national opera of France.

The possibility of a national English opera seems first to have been shewn by Purcell, who, through Humphreys, had learned much from Lulli. His music to Dryden's *King Arthur* is very beautiful, though kept throughout subordinate to the business of the drama. *The Beggar's Opera*, as set to music by Dr Pepusch, was a selection of the airs most popular at the time. It has retained its place on the stage, as also has Dr Arne's *Artaxerxes*, a translation from Metastasio adapted to music rich in melody. The importation of the Italian opera put a stop, for a time at least, to the further development of an opera in England. In 1706, *Armide*, with English words adapted to Italian airs, was performed at Drury Lane. In 1710, *Almahide*, wholly in Italian, was performed exclusively by Italian singers at the Haymarket Theatre; and a succession of attempts of the kind ended in the permanent establishment of the Italian opera. The arrival of Handel in England decided the future progress of the opera. That great master was during the greater part of his life an opera composer and opera manager. He composed for the London stage no fewer than 44

operas, German, Italian, and English. These now forgotten operas were of course not the complex compositions of a later period, which could not have been performed in the then imperfect state of orchestral instruments. A recitative was set to music nearly as fast as the composer could put notes on paper, and the songs were accompanied in general by only one violin and bass, the composer sitting at the harpsichord, and supplying what was wanting. From Handel's time onwards, the opera flourished as an exotic in Britain, the singers being foreign, and the works performed being either Italian or occasionally German or French. Attempts crowned with some measure of success have latterly been made to establish an opera of a national character in England. Balfe's *Bohemian Girl* and *Rose of Castile* have, with other operas by Balfe, Wallace, and Macfarren, attained a measure of popularity. See Hogarth's *Memoirs of the O.* (1851); S. Edward's *History of the O.* (1862); Grove's *Dictionary of Music*.

OPERA-GLASS (Fr. *lorgnette*, Ger. *theater-perspectiv*). This is a double telescope, which is used for looking at objects that require to be clearly seen rather than greatly magnified, such as adjoining scenery and buildings, the performers of a theatre or opera, &c. It is from its use at an opera that it derives its name. The opera-glass is short and light, and can be easily managed with one hand. Its small magnifying power (from 2 to 3 at the most), and the large amount of light admitted by the ample object-glass, enable it to present a bright and pleasing picture, so that the eye is not strained to make out details, as in telescopes of greater power, which generally shew a highly magnified but faint picture. It allows the use of both eyes, which gives to the spectator the double advantage, not possessed by single telescopes, of not requiring to keep one eye shut, a somewhat unnatural way of looking, and of seeing things stand out stereoscopically as in ordinary vision. The opera-glass is in consequence the most popular of telescopes, and requires almost no art in its use.

The opera-glass is the same in principle as the telescope invented by Galileo. It consists of two lenses, an object lens, and an eye-lens. The object-lens is convex, and the eye-lens concave. They are placed nearly at the distance of the difference of their focal lengths from one another. Fig. 1 represents the action of the telescope; o is the object-lens, and e the eye-lens, and oe is the axis of the instrument. The object-lens would form

Fig. 1.

an image, cab , of the object looked at at or near its focus, but the eye-lens intervening, converts the light converging to cab to light diverging apparently from an object in front, CAB . To shew more clearly the changes which the light undergoes, the course of a pencil of rays proceeding from the top of an object is traced. The ray proceeding from the top of the object to the centre of the lens, o , makes an angle, roA , with the axis. This

is the same as the angle aob ; and either of these angles gives half the angle under which the object is seen to the unaided eye. The three extreme rays, r, r, r , of the pencil appear in the figure nearly parallel, although they come from a point. The object is at a considerable distance from the object-glass or eye, so that it is not possible in so limited a figure to shew their divergence. After passing through the object-lens, the three rays proceed to the point b , in the image which the object-lens would form at cab , if no eye-lens were there. This image, as shewn in the figure, is inverted, and would be seen as such if the eye were placed about ten inches (the distance of distinct vision) behind it. The three rays in question do not reach the point b in consequence of the eye-lens intervening, and their course onwards to that point, after passing the eye-lens, is shewn by dotted lines. The actual course, after passing the second lens, is shewn again by the full lines, r, r, r , which to the eye placed immediately behind the eye-lens appear to proceed from the point B in front. As the light comes from B in the same direction as it comes from the actual point in the object, the image is erect. What holds for the point B , holds for every point in the image and object. To find the magnifying power, it is necessary to join Be and Ce , and produce the lines thus formed to b and c . As the eye is placed immediately behind the eye-lens, the angle under which the magnified object is seen is the angle BeC , which is equal to ceb . Now, the angle under which the object itself is seen at o or at e —for the slight difference has no effect at the distance at which objects require to be seen by a telescope—is twice the angle roA , or which is the same thing, the angle cob . The ratio of the angle ceb to the angle cob , which is the magnifying power, is easily seen to be the same as that of the line oe to the line oa . But oe is the focal length of the eye-glass, and oa is the focal length of the object-glass, so that the magnifying power of the instrument is the number of times the focal length of the eye-glass is contained in that of the object-glass. The longer, therefore, the focal length of the object-lens, or the shorter the focal length of the eye-lens, the greater the magnifying power. This may be practically expressed thus: the flatter the object-lens, and the hollower the eye-lens, the more are objects magnified by the glass. The magnifying power may be found with sufficient accuracy by looking at an object with one eye through the tube and the other eye unaided, and so handling the glass that the magnified image seen by the one eye is superposed on the object seen by the naked eye, when a comparison of their relative sizes can be easily made. For great magnification, the instrument requires to be greatly lengthened—a condition inconsistent with its use as an opera-glass. In addition, a high magnifying power is attended with the disadvantage that the field of view, or amount of object or objects seen, becomes too limited. On screwing out the instrument, it will be seen that objects increase in size as the instrument is lengthened, but that the picture becomes more and more limited, shewing that a large power and a large field are incompatible. The opera-glass need not be set to the same precise point as is necessary with ordinary terrestrial telescopes, as the lengthening or shortening of the instrument does not produce so decided an effect on the divergence of the light; the change of divergence, caused by screwing the opera-glass out or in, is so slight as not much to overstep the power of adjustment of the eye, so that an object does not lose all its distinctness at any point within the range of the instrument. There is, however, a

particular point at which an object at a certain distance is best seen.

Fig. 2 gives a section of the opera-glass, which is sufficiently simple to require no further description. The two telescopes are identical in construction,

Fig. 2.

and are placed parallel to each other. The blending of the two images is easily effected by the eyes, as in ordinary vision. Opera-glasses have now come into such demand, that they form an important article of manufacture, of which Paris is the great seat. So largely and cheaply are they produced in Paris, that it has nearly a monopoly of the trade. They may be had from 2s. 6d. to £8 or £7. The cheapest opera-glasses consist of single lenses, those of the better class have compound achromatic lens. A very ordinary construction for a medium price is to have an achromatic object-lens, consisting of two lenses and a single eye-lens. In the finest class of opera-glasses, which are called *field-glasses*, both eye-lenses and object-lenses are achromatic. Plössl's celebrated field-glasses (Ger. *Feldstecher*) have twelve lenses, each object-lens and eye-lens being composed of three separate lenses.

OPERCULUM (Lat. a lid), a term used in botany chiefly to designate the lid or covering of the mouth of the urn or capsule (*theca*) which contains the spores of mosses. Before the ripening of the spores, the operculum is generally concealed by the *calyptra*; but after the *calyptra* has been thrown off, the operculum itself also generally falls off, leaving the peristome visible, and the mouth of the urn open. In some cases the operculum does not fall off, and the urn opens by valves.

In Zoology, the term operculum is chiefly employed to denote the covering which many gasteropod molluscs form for the mouth of their shell. It is attached to the back of the foot of the mollusc. In some it is calcareous, forming a shelly plate; in some it is horny; whilst gasteropods very nearly allied to those which possess it, are destitute of it altogether. The operculum increases in various ways, so as to present in different genera great diversity of structure, concentric, spiral, unguiculate, &c.

OPHICEPHALUS, a genus of fishes, of the family *Anabasidae* (q. v.), sometimes regarded as constituting a distinct family *Ophicephalidae*, because there is a mere cavity for retaining water to supply the gills, and no pharyngeal lamina, and because of the long eel-like form and the flattened head, which is covered with large scales. Some of them are common in the fresh waters of the East Indies, are

often found among wet grass, often travel from one pool to another, and are capable of subsisting for a long time in half-dried mud, descending into it when the pools dry up. The *CORA-MOTA* or *GACHUA* of India (*O. gachua*) is much used for food by the natives, although generally rejected by Europeans on account of its very snake-like appearance. It is very tenacious of life, and is not only brought to the Indian markets alive, but is cut to pieces whilst still living for the convenience of buyers.

O'PHICLEIDE (Gr. *ophis*, serpent, and *kleis*, key), a musical wind-instrument of brass or copper, invented to supersede the Serpent (q. v.) in the orchestra and military bands. It consists of a conical tube, terminating in a bell like that of the horn, with a mouthpiece similar to that of the serpent, and ten ventages or holes, all stopped by keys like those of the bassoon, but of larger size. Ophicleides are of two kinds, the bass and the alto. The bass ophicleide offers great resources for maintaining the low part of masses of harmony. Music for it is written in the bass clef, and the compass of the instrument is from B, the third space below the bass staff, to C, the fifth added space above it,

including all the intervening chromatic intervals. The alto ophicleide is an instrument of very inferior quality, and less used. Its compass is also three octaves and one note. The music for it is written in the treble clef, and an octave higher than it is played. Double bass or monster ophicleides have sometimes been used in large orchestras, but the amount of breath which is required to play them has prevented their coming into general use.

OPHIDIA. See SERPENTS.

OPHIOGLOSSEÆ, a suborder of *Filices* or Ferns (q. v.), consisting of a few rather elegant little plants with an erect or pendulous stem, which has a cavity instead of pith, leaves with netted veins, and the spore-cases (*thece*) collected into a spike formed at the edges of an altered leaf, 2-valved, and without any trace of an elastic ring. They are found in warm and temperate countries, but abound most of all in the islands of tropical Asia. Several species are European, and two are British, the *Botrychium* (q. v.) *lunaria*, or Moonwort, and the Common Adder's-tongue (*Ophio-glossum vulgatum*), which was at one time supposed

Ophicleide.

Adder's-Tongue (*Ophio-glossum vulgatum*).

to possess magical virtues, and was also used as a vulnerary, although it seems to possess only a mucilaginous quality; on account of which some of the other species have been employed in broths. It is a very common plant in England, its abundance in some places much injuring pastures.

OPHIR, a region frequently mentioned in the Old Testament, and from which the ships of Solomon, fitted out in the harbours of Edom, brought gold, precious stones, sandal-wood, &c. The voyage occupied three years. Where Ophir was situated, has been a much, in fact, a superfluously disputed question. It was probably either, on the east coast of Africa about Sofala, or in Arabia, or in India, but in which of the three countries is doubtful. Huet, Bruce (the traveller), the historian Robertson, M. Quatremère, &c., are in favour of Africa; Michaelis, Niebühr (the traveller), Gosellin, Vincent, Winer, Fürst, Knobel, Forster, Crawford, and Kalisch, of Arabia; Vitringa, Reland, Lassen, Ritter, Bertheau, and Ewald, of India. Josephus, however, it should be said, placed O. in the peninsula of Malacca, and his very respectable opinion has been adopted by Sir J. Emerson Tennent in his work on Ceylon. For a complete discussion of the point, see Karl Ritter's *Erdrunde* (vol. xiv. 1848), 80 octavo pages of which are devoted to Ophir. According to Ritter, who accepts the view of Lassen, O. was situated at the mouth of the Indus.

OPHIR, called by the Malays, Gunong Pasaman, a volcanic mountain in the highlands of Padang, island of Sumatra, lies in 0° 4' 55" N. lat., and 99° 55' E. long.; the eastern peak, called Telaman, attains the height of 9939 feet above the sea. The western peak is called Pasaman. The numerous inhabitants have cleared off forest and brought under cultivation large tracts of land on the slopes of O., and its base is studded with villages. The O. districts are most beautiful, and the lofty waterfalls, contrasting with the bright-green foliage of the mountain, highly picturesque.

OPHISURUS. See SNAKE-EEL.

O'PHITES (Gr. *ophitai*, 'serpent-brethren,' from *ophis*, a serpent), a sect of Gnostics (q. v.), who while they shared the general belief of dualism, the conflict of matter and spirit, the emanations, the Demiurgos, and other notions common to the many subdivisions of this extraordinary school, were distinguished from all by their peculiar doctrine and worship connected with their *ophis* or serpent. The O., like most other Gnostics, regarded the Demiurgos, or the Jehovah of the Old Testament, with great abhorrence, but they pursued this notion into a very curious development. Regarding the emancipation of man from the power and control of the Demiurgos as a most important end, they considered the serpent who tempted Eve, and introduced into the world 'knowledge' and revolt against Jehovah, to have been the great benefactor of the human race. Hence their worship of the serpent. Some of the details of their system were very strange. We may instance their singular attempt to engraft 'Ophism' on Christianity; their seeking, as it were, to impart to the Christian Eucharist an Ophite character, by causing the bread designed for the Eucharistic sacrifice to be *licked by a serpent*, which was kept in a cave for the purpose, and which the communicants kissed after receiving the Eucharist (*Epiph. Hor.* 37, a. 5). Our information, however, regarding them is very meagre, and comes chiefly from antagonistic sources. The O. originated in Egypt, probably from some relation to the Egyptian serpent-worship, and spread thence into Syria and Asia Minor.

Offshoots of this sect are the Cainites. See CAIN and SETHITES.

OPHIUROIDEA, the Brittle Starfishes (q. v.), a class of Echinodermata (q. v.). See also ZOOLOGY.

OPHTHALMIA (derived from the Greek word *ophthalmos*, the eye) was originally and still is sometimes used to denote inflammation of the eye generally, but it is at the present time usually restricted to inflammatory affections of the mucous coat of the eye, termed the *conjunctiva*.

Before these are considered, two other diseases, still sometimes described under this name, must be noticed: (1) *Ophthalmia tarsi, tinea tarsi* or *blepharitis*, is an inflammation of the edges of the lids, usually chronic and very often neglected. It is a serious condition, however, as it is apt to lead, if unchecked, to loss of eyelashes, and 'blear eyes.' (2) *Sympathetic ophthalmia* is a very insidious and dangerous disease, which is apt to be set up in one eye when the other has been wounded, or is the seat of certain forms of disease. The only preventive is removal of the offending eyeball, and this must be resorted to at the first sign that sympathetic ophthalmia threatens the other; for, when once established, it is peculiarly intractable, and may even lead to total destruction of the eye attacked by it.

The most important forms of ophthalmia, in the restricted sense of the word, are:

1. *Catarrhal Ophthalmia*.—Its leading symptoms are redness of the surface of the eye (the redness being superficial, of a bright scarlet colour, and usually diffused in patches), sensations of uneasiness, stiffness and dryness, with slight pain, especially when the eye is exposed to the light; an increased discharge, not of tears, except at the beginning of the attack, but of mucus, which at first is thin, but soon becomes opaque, yellow, and thicker; pus (or matter, as it is popularly termed) being seen at the corner of the eye, or between the eyelashes along the edges of the lids, which it glues together during the night. The disease results in most cases from exposure to cold and damp, and is very apt to be excited by exposure to a draught of air, especially during sleep. It is popularly known as a *cold* or a *blight* in the eye. The usual domestic treatment by the application of wet cloths, bread poultices, &c., is most mischievous, and cannot too strongly be condemned. This disease is generally easily checked by the application of a mild astringent wash (alum 3 grains, or boracic acid 10 grains, to the ounce of water), to the eye 3 or 4 times daily; and of some ointment to the edges of the lids, to prevent adhesion during sleep. If it become chronic, it is best treated by touching the conjunctiva of the lids every second or third day with a solution of nitrate of silver, 10 or 15 grains to the ounce of water.

2. *Purulent Ophthalmia* is often indistinguishable at its onset from catarrhal ophthalmia, but soon becomes much more severe, and is extremely apt to lead to ulceration or complete destruction of the cornea, and consequent great impairment or entire loss of vision. Three varieties may be distinguished, which differ, however, more in their causation, mode of occurrence, and severity, than in their essential symptoms: (a) *purulent ophthalmia of adults*, or Egyptian ophthalmia; (b) *purulent ophthalmia of newly-born children*; (c) *gonorrhoeal ophthalmia*. One description will suffice for all the forms. The conjunctiva rapidly becomes intensely red, and soon appears raised from the sclerotic by the effusion of serum between them, projecting around the cornea, which remains buried, as it were, in a pit. Similar effusion takes place beneath the mucous membrane lining the eyelids, causing them to pro-

ject forwards in large livid convex masses, which often entirely conceal the globe of the eye. These symptoms are accompanied by severe burning pain, great headache, fever, and prostration. The disease may be arrested at this stage, and end in complete recovery, or may involve the cornea, and lead to permanent injury, or loss of the eye. (a) Egyptian ophthalmia got that name because it was imported from Egypt (where, as in other hot countries, it is very common) by our troops in the beginning of this century into England. It is not very often met with in Britain. (b) Ophthalmia of newly-born children usually begins about the third day after birth. It is very common, but very often neglected; and, though much more amenable to treatment than the other forms, is the cause of about one-third of the cases of blindness occurring in Europe. (c) Gonorrheal ophthalmia is caused by the application of discharge from a gonorrhea to the eye, and is hence most common in persons suffering from that disease. It is the most severe form of purulent ophthalmia.—*Treatment*—All the forms are very dangerous to the sight, and medical advice should be obtained at once on the slightest suspicion of the presence of this disease. All are highly contagious; cleanliness must be scrupulously maintained, and the greatest care taken not to let the discharge from an affected eye come in contact with a healthy one.

3. *Diphtheritic Ophthalmia* is even more dangerous and destructive than purulent ophthalmia, which it much resembles. It differs in that the discharge adheres to the conjunctiva in the form of a membrane.

4. *Pustular or Phlyctenular Ophthalmia*, often called *strumous ophthalmia*, is very common, especially in children, and is usually associated with weak health, in which case it is very troublesome, and apt to return. It is, however, seldom serious. It is characterised by the appearance at or near the margin of the cornea of small reddish or yellow elevations, with reddening of the conjunctiva, usually in limited bands directed inwards towards them. In troublesome cases, there is great irritability of the eyes, and sensitiveness to light.—*Treatment*—The application of mercury, either in the form of calomel, or of a weak mercurial ointment, is the treatment most generally useful. But attention must always be paid to the general health, by means of fresh air, good food, cleanliness, and the administration of strengthening medicines, especially cod-liver oil and iodide of iron.

5. *Granular Ophthalmia, granular lids, or trachoma*, is a very chronic and severe form of inflammation, often leading to puckering of the conjunctiva, with turning in of the eyelashes, so that they touch the globe, and to opacity of the cornea. It is believed to be contagious, and is certainly most apt to occur in overcrowded and ill-ventilated dwellings. Some races (e.g., the Jews and the Irish) are specially liable to it. It consists in the appearance on the conjunctiva of the lids of numerous elevations, either red and flesh-like, or pale and sago-like, with pain, itchiness, great irritability of the eyes to light, and much watery or mattery secretion. The best treatment is the application to the affected parts of solid sulphate of copper, or a solution of nitrate of silver, 10 to 20 grains to the ounce of water. It is, however, extremely difficult to cure, and very apt to return.

OPHTHALMOSCOPE, THE, is an instrument by which the interior of the eye can be examined. It was invented in 1851 by Professor Helmholtz, who shewed that, by illuminating and examining an eye in the same direction, its deeper parts can be rendered visible. All forms of ophthalmoscopes are adaptations

of this principle. The form now generally in use consists of a concave mirror of about 10 inches focus, 1 to 3 inches in diameter, with a small hole in the centre; and certain lenses to use with it, the most important of them a separate convex lens of 2½ inches focus, and 1½ to 4 inches in diameter. Examination is facilitated by dilating the pupil of the observed eye with atropin; and for a complete examination, this is often indispensable. The person whose eye is to be examined is seated in a darkened room, with a bright light, e.g., a good gas-burner, on a level with his eye by the side of his head. The observer sits opposite him, and placing the mirror close to his own eye, and about 18 inches from the eye to be examined, reflects the light upon the latter, while he looks at it through the hole. The pupil in a healthy eye appears of a bright red or orange instead of its usual deep black. In short-sighted and long-sighted eyes, but not in normal ones, the vessels of the retina, the entrance of the optic nerve, &c., can be distinctly seen, and by their movements the deviation from the normal refraction can roughly be estimated. Opacities in the lens (Cataract, q. v.) or vitreous humour appear black, and are discovered by this method more certainly and easily than by any other. The details of the retina, choroid, &c. (or *fundus*), can be seen in two different ways. In the *indirect method* the observer, seated as above described, holds the 2½-inch convex lens about 3 inches from the eye under examination, between it and his own, when a clear image of part of the fundus, inverted and magnified about 4 diameters, appears in the red light of the pupil. In the *direct method*, the observing eye must be placed as close to the observed as the intervention of the mirror will allow, when an image of a smaller part of the fundus is seen, but erect and magnified about 14 diameters. The fundus appears of an orange or red colour, varying much in different individuals; the blood-vessels of the retina are seen as darker red lines coursing over it. The entrance of the optic nerve, commonly called the *disc*, from which these vessels diverge, appears as a round disc of a much paler colour. The ophthalmoscope has revolutionised this department of medicine, as most of the deeper affections of the eye, particularly of the optic nerve, choroid, and retina, were before only recognisable after the eyeball was removed from the body. Some of these affections have, moreover, important relations to general diseases, e.g., Bright's disease, diabetes, diseases of the brain and spinal cord, and general medicine has benefited accordingly. It has also much facilitated the discovery and correction of errors of refraction (short- and long-sightedness, astigmatism).

OPIE, JOHN, R.A., was born at the village of St Agnes, seven miles from Truro, Cornwall, in May 1761. His father, a master-carpenter, wished him to follow the same trade, but his bias for art was strong; and his attempts at portrait-painting secured the friendly help of Dr Wolcott ('Peter Pindar'). In 1780, he was taken to London by Dr Wolcott, and immediately came to be acknowledged by the fashionable world as the 'Cornish Wonder.' This tide of good-fortune soon ebbed, but not before O. had realised a moderate competency. The loss of popular favour, however, only served to bring out more strongly O.'s manly independence and strong love of art. He stooped to no device to retain fashionable patronage, but calmly entered on that department of painting which was then regarded as the only style of high art, namely, historical or scriptural subjects, executed on a large scale. His pencil was employed by Boydell in his well-meant and magnificent scheme to elevate British art; he also painted a number of works in the illustra-

tion of Bowyer's English History, Macklin's Poets and Biblical Gallery, and other similar undertakings. His pictures of the 'Murder of James I. of Scotland,' 'the Slaughter of Rizzio,' 'Jephtha's Vow,' 'Presentation in the Temple,' 'Arthur and Hubert,' 'Belisarius and Juliet in the Garden,' are his most noted works. O. was elected an Associate of the Royal Academy in 1786, and Academician in the following year. He devoted part of his time to various literary efforts tending to the illustration of art: these were chiefly the 'Life of Reynolds' in Dr Wolcott's edition of Pilkington's *Dictionary of Painters*; a letter in the *North Briton*, recommending the formation of a National Gallery, reprinted as *An Inquiry into the Requisite Cultivation of the Fine Arts in Britain*; and lectures on art, delivered at the Royal Institution. Appointed Professor of Painting, he delivered four lectures in that capacity. O. was twice married. He obtained a divorce from his first wife; his second was well known as one of the most popular novelists of the day. He died somewhat suddenly in his house, St Bernard Street, Oxford Street, April 9, 1807, and was buried in the crypt of St Paul's, near the grave of Reynolds.—MRS OPIE, the daughter of a Norwich physician, Dr Alderson, was born in 1769, and while very young, wrote songs and tragedies. She was married to Opie in 1798. In 1801 her first novel, *Father and Daughter*, appeared; next year, a volume of graceful poems. *Adeline Mowbray* and *Simple Tales* were her next works. On her husband's death she returned to Norwich, and published a memoir of her husband, prefixed to his lectures; also *Temper*, *Tales of Real Life*, *Valentine's Eve*, *Tales of the Heart*, and *Madelaine*. She became a Quaker in 1825, and afterwards published *Detraction Displayed*, and articles in periodicals. She died in 1853.

OPINICUS, one of the fabulous creatures known in Heraldry, with the head and neck of an eagle, the body of a lion, wings, and a short tail like that of a camel.

OPINION OF COUNSEL is the technical name for the advice given by a barrister or advocate. The attorney or solicitor writes a statement of facts, called 'a case' in England, and 'a memorial' in Scotland, which ends by asking certain queries, and the answer written by the counsel is his opinion. A counsel is not liable for any damages caused by his giving a wrong opinion though the result of gross ignorance, this being one of the privileges of counsel.

OPITZ, MARTIN, a famous German poet, was born December 23, 1697, at Bunzlau, in Silesia. He received an education of the highest kind; and after some time spent at the court of the Duke of Liegnitz, he accepted, in 1622, an invitation by Bethlen Gabor, Prince of Transylvania, to teach Philosophy and the *Humaniora* at Weissenburg; but disliking the rudeness of the country, he soon returned to the court of the Duke of Liegnitz. In 1624, his first poems were published, and in the same year his work *Von der deutschen Poeterei*, in which he laid the foundation of a system of German poetics. In 1625, he went to Vienna, where, on account of an elegy on the death of an archduke, he received a laurel crown from the hands of the emperor, Ferdinand II. In 1626, he became secretary, although a Protestant, to the Burggraf Karl Hannibal of Dohna, a distinguished Roman Catholic and imperialist, and was employed in various transactions with foreign courts. In 1629, the emperor raised him to the rank of nobility. After the death of the Burggraf of Dohna, in 1633, he returned to the courts of Liegnitz and Brieg. About this time he published *Venus*, a didactic

poem, and his *Trostgedicht in Widerwärtigkeit des Kriegs*, the best of his poems, which were followed by an opera called *Judith*, a translation of the *Antigone* of Sophocles, and a translation of the Psalms. In 1638, he was appointed Secretary and Historiographer to Ladislaus IV. of Poland. But in the midst of his days, and when he had attained to fame and prosperity, he was cut off by the plague at Danzig, August 20, 1639. O. was more honoured by his contemporaries than almost any other poet ever was. German poetry, which had been neglected and despised, began again to be esteemed and cultivated. The popularity of O., and his relations with the chiefs of the Roman Catholic party, led to the adoption, throughout the whole of Germany, of the form given to the German language by Luther, which had previously obtained general acceptance only in the Protestant states. His poetry is characterised by careful attention to language and metre, and by reflection rather than by brilliant fancy or deep feeling. There are several editions of his works, but none is quite complete (3 vols. Breslau, 1690; 3 vols. Amst. 1646; and 3 vols. Frankfurt and Leipzig, 1724).

OPIUM, one of the most valuable of medicines, is the dried juice of the unripe capsules of a species of Poppy (q. v.), *Papaver somniferum*, sometimes called the Common Poppy, and sometimes the White Poppy, although the latter name is really appropriate only to one of its varieties. The plant is probably a native of some of the warmer parts of Asia, although it is now common in cultivated and waste grounds throughout all the south and middle of Europe, and is occasionally found in Britain. It is an annual, varying in height from one to six feet, erect, branched, of a glaucous green colour, with ovate-oblong sessile leaves, the stem and leaves generally smooth, the branches terminated by large flowers on long stalks, the capsules globose or roundish-ovate and smooth. There are two principal varieties cultivated for the opium which they yield, which have been regarded by some botanists as distinct species; the one (*Papaver somniferum*) having generally red or violet-coloured flowers, numerous flower-stalks rising together, globose capsules opening by a circle of pores under the persistent stigma, and black seeds; the other (*P. officinale*) having white flowers, solitary flower-stalks, the capsules somewhat ovate, the circle of pores almost wanting, the seeds white. The former variety is generally cultivated in the mountainous parts of the north of India, the latter in the plain of Bengal, where the poppy-fields are described by Dr Hooker as resembling green lakes studded with white water-lilies. The cultivation of the poppy for the sake of opium is carried on in many parts of India, although the chief opium district is a large tract on the Ganges, about 600 miles in length and 200 miles in breadth, which was divided by the East India Company into two agencies, that of Behar and that of Benares, the central factory of the former being at Patna, and that of the latter at Ghazee-pore. The poppy is also extensively cultivated for opium in the Asiatic provinces of Turkey, in Egypt, and in Persia. Opium of very good quality is also produced, although not to any considerable amount, in some parts of Europe, and even in Britain. It is sometimes alleged that a much warmer climate than that of Britain is requisite for the profitable production of opium, but the chief fault of the climate seems rather to be the frequency of wet weather. Very fine specimens of opium have been produced, and the produce per acre has been found amply remunerative; but a great difficulty is experienced in obtaining labour at a moderate rate for a few days only at a time,

and when the experiment is conducted on a small scale, only for a few hours daily. This difficulty was much felt in an experiment, otherwise most successful, which was made at Edinburgh, by Mr Young, a surgeon, who about the year 1830 obtained 56 lbs. of opium from one acre of poppies, and sold it at 36s. a lb. It was of excellent quality. His mode of cultivation was similar to that usual in India. The seed being sown in spring on a rich soil, the plants were kept clear of weeds, and when they had flowered and produced capsules, incisions were made in the capsules, and the exuded juice collected as described below. The capsules vary from the size of a hen's egg to that of the fist. In India, the poppy flowers in the end of January and beginning of February.

The poppy requires for its profitable cultivation a rich soil, and in India is generally sown in the neighbourhood of villages where manure can be easily obtained. The soil ought to be fine and loose when the seed is sown. The subsequent cultivation consists chiefly in thinning and weeding. Irrigation is practised. Mild moist weather, with night-dews, is deemed most favourable during the time of the collection of the opium. Very dry weather diminishes the flow of the juice, and much rain is injurious.

The opium poppy is cultivated for other purposes besides the production of opium, concerning which see *POPPY*.

Opium, as a commercial article, is of great importance, exceeding indeed that of any other drug in use, and the cultivation of the opium poppy (*Papaver somniferum*) in British India forms a most extensive branch of agriculture, and the collection and preparation of the drug itself employs a large number of persons in the Patna, Malwa, and Benares districts of Bengal. Indeed during the whole existence of the East India Company, the production of this drug was of the first importance; its employment as a habitual narcotic, as well as a medicine amongst all the eastern nations, demands an enormous supply. The seed is sown in India in

Fig. 1.

the beginning of November; it flowers in the end of January, or a little later; and in three or four weeks after, the capsules or poppy-heads are about the size of hens' eggs, and are ready for operating upon. When this is the case, the collectors each take a little iron instrument, called a *nushtur* (fig. 1); it is made of three or four small plates of iron, narrow at one end and wider at the other, which is also notched like a saw; with these instruments they wound each full-grown poppy-head (fig. 2) as they make their way through the plants in the field (fig. 3). This is always done early in the morning, before the heat of the sun is felt; during the day the milky juice of the plant oozes out, and early on the following morning it is collected by scraping

Fig. 2.

it off with a kind of scoop, called a *sittoocha*, and transferred to an earthen vessel, called a *kurrace*,

hanging at the side of the collector. When this is full, it is carried home and transferred to a shallow open brass dish, called a *thalce*, and left

Fig. 3.

for a time tilted on its side, so that any watery fluid may drain out; this watery fluid is called *pusseewah*, and is very detrimental to the opium unless removed. It now requires daily attendance, and has to be turned frequently, so that the air may dry it equally, until it acquires a tolerable consistency, which requires three or four weeks; it is then packed in small earthen jars, and taken to the *godowns* or factories; here the contents of each jar are turned out and carefully weighed, tested, valued, and credited to the cultivator. The opium is then thrown into vast vats, which hold the accumulations of whole districts, and the mass being kneaded, is again taken out and made into balls or cakes for the market.

This is a very important operation, and is conducted in long rooms, the workmen sitting in rows, closely watched by the overseers to insure the work being carefully performed. Before each workman (fig. 4) is a tray, and within easy reach is placed the

Fig. 4.

tagar, a tin vessel for holding as much opium as will make three or five balls. On the tray is another basin containing water, and a smaller tray; on this tray stands a brass cup, into which the ball or cake is moulded, also a supply of thin layers of poppy petals, formed by laying them out overlapping each other, and pressing them upon one another; these are prepared by women in the poppy-fields, and with these is a cup filled with a sticky fluid called *lewah*, made from opium of inferior quality. The operator

OPIUM.

begins his work by taking the brass cup and placing on its bottom one of the cakes of poppy petals, which he smears over with the *lewah*; then adds other cakes of petals to overlap and adhere to the first, until the cup is lined and a coat of petals is thus formed for the opium, of which he takes the exact quantity as near as he can guess, works it into a ball, and places it in the basin, so that the lining of petals encloses it and sticks to it, in consequence of the *lewah* smeared on the inner side of the thin cakes of petals. Other petals are put on the upper part of the ball, and the whole gathered round it, forming a case about as thick as a bank-note. Each man's work for the day is kept by itself, and after having been duly registered, is taken to a vast drying-room (fig. 5), where the balls are placed in tiers on lattice-

Fig. 5.

work racks, and are continually turned and examined by boys, to keep them from insects and other injuries. After being fully dried, these balls are packed in chests for the market.

The manufacture of opium is carried on to the greatest extent in India, but large quantities are also made in Turkey, and this latter is considered the best in quality. It is also made at Trebizond in Persia, and in Egypt; occasionally it has been produced in Germany, France, and England. Of the Indian opium there are several qualities, as Bengal, Patna or Benares opium, Garden Patna, Malwa, fine Malwa, Cutch, and Kandeish opium.

The opium revenue for India in 1875-1876 was given at £8,471,425. The number of chests sold was 49,695, at £139 per chest, or £26 higher than the previous year's average. The net profit was £90 per chest. The area under cultivation in Bengal and Bombay was 560,608 acres. In 1880-81, 92,190 chests of opium, valued at £13,600,148, were exported. Next to China, the largest consumption of Indian opium is by the Burmese and the natives of the Malacca Straits, who take annually to the value of nearly a million sterling.

In Europe, with very slight exceptions, opium is used for medicinal purposes only, and large quantities of it undergo a still further stage of manufacture, in order to separate from it the active principles morphine, narcotine, &c. In Great Britain, the chief manufacture of these salts of opium is carried on in Edinburgh, where two firms, Messrs T. and H. Smith, and J. F. Macfarlane & Co., have attained great reputation, and manufacture these products upon an immense scale, supplying probably a fifth of the whole quantity manufactured.

Chemical and Medicinal Properties.—The only variety recognised in the British pharmacopœia is the Turkey opium. The chemical composition of opium has been studied by various chemists, amongst whom must be especially mentioned Professor Mulder of Utrecht, and Professor Anderson of Glasgow. The following constituents occur in most kinds of opium :

	Meconic Acid, $3\text{HO}, \text{C}_{14}\text{H}_9\text{O}_{11}$, from 4 to 8 per cent.
Organic Bases or Alkaloids.	Morphia, . . . $\text{C}_{17}\text{H}_{19}\text{NO}_3$, from 4 to 12 "
	Codeia, . . . $\text{C}_{18}\text{H}_{21}\text{NO}_3$, less than 1 "
	Thebaia, . . . $\text{C}_{18}\text{H}_{21}\text{NO}_3$, " "
	Papaverine, . . . $\text{C}_{40}\text{H}_{51}\text{NO}_8$, " "
	Narcotine, . . . $\text{C}_{46}\text{H}_{57}\text{NO}_{14}$, from 6 to 10 "
	Narceia, . . . $\text{C}_{46}\text{H}_{57}\text{NO}_{13}$, from 6 to 13 "
	Meconine, . . . $\text{C}_{20}\text{H}_{10}\text{O}_8$, less than 1 "
	Resinous Matter, from 2 to 4 "
	Caoutchouc, . . . from 4 to 6 "
	Mucilage, Gum, and Extractive } from 40 to 50 "
	Matters, . . . }

In addition to the six alkaloids named in this table, a seventh, named opianine, has been found in Egyptian opium, but in no other varieties.

Some of the most important and characteristic of these constituents, as meconic acid, morphia, and narcotine, are noticed in special articles. The only isolated constituents of opium which are now used in medicine are *Codeia* (so called from the Greek word *kōdeia*, a poppy-head), which has been asserted by Magendie and others to act in the same manner as, although less powerfully than, morphia, but which is now seldom prescribed, as it is not a pharmacopœial preparation; and *Morphia*, which has already been described.

The only test given in the British pharmacopœia for the purity of opium is the determination of its percentage of morphia, which is a process requiring a considerable amount of chemical skill.

Following the arrangement adopted by Pereira (*Elements of Materia Medica*, 4th ed.), we have just quoted, we shall consider (1) the effects of one or a few doses of opium employed medicinally or as a poison; (2) the effects of the habitual employment of opium, either by chewing or smoking it; and (3) its good and bad effects on the different systems of organs.

1. In *small doses*, as from a quarter of a grain to a grain, it acts as an agreeable stimulant, this effect being followed by a desire to sleep, accompanied by dryness of the mouth and throat, thirst, and slight constipation. When it is given in a *full medicinal dose* (as from two to four grains), the stage of excitement is soon followed by well-marked depression or torpor, both of the bodily and mental organs, and an almost irresistible sleepiness; these effects being usually succeeded by constipation, nausea, furred tongue, headache, and listlessness. When it is administered in a dangerous or poisonous dose, the symptoms, as summed up by Dr Christison in his work *On Poisons*, begin with giddiness and stupor, generally without any previous stimulus. The stupor rapidly increasing, the person becomes motionless, and insensible to external impressions; he breathes very slowly, generally lies quite still, with his eyes shut and the pupils contracted; and the whole

expression of the countenance is that of deep and perfect repose. As the poisoning advances, the features become ghastly, the pulse feeble and imperceptible, the muscles exceedingly relaxed, and, unless assistance is speedily procured, death ensues. If the person recovers, the insensibility is succeeded by prolonged sleep, which commonly ends in twenty-four or thirty-six hours, and is followed by nausea, vomiting, giddiness, and loathing of food.

2. The *habitual use of opium*, whether the drug be eaten or smoked, is undoubtedly in most cases injurious to the constitution, although probably not to the extent that some eastern travellers assert. Sir R. Christison, and other eminent physicians, have shewn that in numerous cases very large quantities of this drug may be regularly taken with impunity; and Dr Chapman (*Elements of Therapeutics*, vol. ii. p. 199) relates two remarkable cases of this kind—one in which a wineglassful of laudanum was taken several times in the twenty-four hours, and another (a case of cancer of the uterus) in which the quantity of laudanum was gradually increased to *three pints* daily, a considerable quantity of solid opium being also taken in the same period.

Opium-smoking is a habit that is chiefly confined to China and the islands of the Indian Archipelago. An extract, called *chandoo*, is made into pills about the size of a pea. The following is the account given by Marsden, in his *History of Sumatra*, of the process employed: 'One of these pills being put into the small tube that projects from the side of the opium pipe, that tube is applied to a lamp, and the pill being lighted is consumed at one whiff or inflation of the lungs, attended with a whistling noise. The smoke is never emitted by the mouth, but usually receives vent through the nostrils.' Although the immoderate practice of opium-smoking is most destructive to those who live in poverty and distress, yet from the evidence of Mr Smith, a surgeon resident at Pulo Penang, and of Dr Estwell, who passed three years in China, it does not appear that the Chinese in easy circumstances, and who have the comforts of life about them, are materially affected in respect to longevity by addiction to this habit.

3. As the discussion of the physiological action of opium on the different organs would, in its most condensed form, occupy too much space, we shall confine our remarks to the practical conclusions at which physiologists and physicians have arrived respecting the utility and the danger of prescribing this drug in various conditions of the principal vital organs.

a. *Cerebro-spinal System*.—Under proper regulations it is a remedy which may be used to stimulate the circulation within the cranium, to promote sleep, to diminish abnormal or increased sensibility, and to allay pain generally; while it is contra-indicated in apoplexy, cerebral inflammation, paralysis, and hysteria. Dr Pereira relates a case in which *one grain* of opium, administered to an hysterical young woman, proved fatal.

b. *Digestive System*.—'Under proper regulations,' says Pereira, 'opium is an admissible remedy for the following purposes: to diminish excessive hunger; to allay pain, when unaccompanied by inflammation; to diminish the sensibility of the digestive organs in cases of acrid poisoning, and in the passage of biliary calculi; to produce relaxation of the muscular fibres of the alimentary canal in colic, and of the gall-ducts in the passage of calculi, and to diminish excessive secretion from the intestinal canal in diarrhoea;' while it is contra-indicated 'in diminished secretion from the gastro-intestinal membrane, in extreme thirst, in loss of

appetite and weak digestion, in obstinate costiveness, and in diminished excretion of bile.'

c. *Vascular System*.—In vascular excitement with great diminution of power, as after hemorrhage, opium is often serviceable; but when the pulse is strong as well as quick, or when there is simultaneously a tendency to abnormal sleepiness, it is contra-indicated.

d. *Respiratory System*.—'Opium, under proper regulations, may be useful to diminish the contractility of the muscles of respiration, or of the muscular fibres of the air-tubes, as in spasmodic asthma; to diminish the sensibility of the bronchia in the second stage of catarrh, and thereby to allay cough by lessening the influence of the cold air; and, lastly, to counteract excessive bronchial secretion;' while it is contra-indicated in difficulty of breathing, arising from a deficient supply of nervous energy, as in apoplectic cases; in cases in which the venous is imperfectly converted into arterial blood; and in the first stage of catarrh and pneumonia, both from its checking secretion, and from its tendency to impede the due arterialisation of the blood.

e. *Urinary System*.—Opium is a valuable remedy to allay the pain in the kidney and adjacent parts in cases of renal calculi, and also to produce relaxation of the ureters when the calculi are passing along these tubes; it is also of great service in certain forms of irritable bladder.

There can be no doubt that the essential and primary operation of opium is on the nervous system, the other effects being for the most part secondary.

Opium is undoubtedly the most valuable remedy of the whole materia medica. 'For other medicines,' says Dr Pereira, 'we have one or more substitutes; but for opium, none—at least in the large majority of cases in which its peculiar and beneficial influence is required.' We not only exhibit it to mitigate pain, to allay spasm, to promote sleep, to relieve nervous restlessness, to produce perspiration, and to check profuse discharges from the bronchial tubes and intestinal canal; but we also find it capable of relieving some diseases in which none of the above indications can be always distinctly perceived. In combination with tartar emetic, it has been strongly recommended in fever with much cerebral disturbance; in association with calomel, it is the most trustworthy remedy in cases of inflammation of membranous parts; in insanity, its value cannot be overestimated; it is the remedy chiefly trusted to in delirium tremens; it is more serviceable than any other medicine in diabetes; and to conclude with a more common and less serious affection, its efficiency, when administered in small doses (as ten or fifteen drops of laudanum three times a day), in promoting the healing of ulcers in which granulation proceeds too slowly is very marked.

In addition to the solution of Muriate of Morphia (q. v.), which, on the whole, is the best preparation of opium for internal use in the majority of cases, the British pharmacopoeia contains an opium pill (containing one part of opium in five of the pill); a pill of lead and opium (chiefly used in pulmonary hemorrhage); an aromatic powder of chalk and opium (containing one part of opium in forty of the powder); powder of ipecacuan and opium (or Dover's Powder [q. v.], containing one part of opium in ten of the powder); powder of kino and opium (containing one part of opium in twenty of the powder, and, like the aromatic powder, chiefly used in diarrhoea); tincture (see LAUDANUM), and camphorated tincture of opium (commonly known as Paregoric Elixir, and much used in chronic cough—containing two grains of opium in the fluid ounce); in addition to an enema;

a wine (used chiefly as a local application to the eye in cases of ophthalmia); an ointment of galls and opium (used as an external application to piles); and a liniment and a plaster, which are applied to remove local superficial pains.

In a case of poisoning by opium, the first and most essential point is the evacuation of the contents of the stomach. The stomach-pump, if it can be procured, should be employed, and strong coffee should then be pumped into the stomach after the removal of its contents. The next best remedy is an emetic of sulphate of zinc (about a scruple), and if this is not at hand, a dessert-spoonful of flour of mustard, stirred up in a tumbler of warm water, will usually produce the desired effect. The patient must, if possible, be prevented from falling asleep, and for this purpose he should be kept constantly walking between two strong men, while a third person in the rear should, at short intervals, flick him sharply with a rough wet towel, or (if procurable) a good birch rod. Cold water should also be occasionally dashed over the head and chest. In a few apparently hopeless cases, death has been averted by artificial respiration, and by the application of electro-magnetism.

OPOBALSAMUM. See BALSAM and GUM.

OPODELDOC is a popular synonyme for *Soap Liniment* (q.v.). The origin of the term, which was apparently applied by Paracelsus to various forms of liniments or local applications, is not known. The *opo* is the same as the *opo* of *opopanax*, *opobalsamum*, &c., and is doubtless derived from the Greek *ῥπος*, juice. It has been suggested by an eminent Anglo-Saxon scholar that the original word was *opodilla*, and that *doc* or *dock* was added merely as a gloss to *dilla*—a view that is confirmed by the fact, that in *Ælfric's Glossary*, *dill* (*dilla*) is Englished by *dock*.

OPO'PONAX, a gum resin obtained by puncturing the roots of a species of parsnip (*Pastinaca Opoponax*). The chief interest in this material is the great importance which the ancient physicians attached to it as an antispasmodic medicine. It was employed by Hippocrates, Theophrastus, and Dioscorides, who have each left descriptions of it. The plant grows generally throughout Southern Europe, and the gum is still collected, but is not much used.

OPORTO (Portug. *O Porto*, the port), a city of Portugal, and, after Lisbon, the most important seaport of the country, in the province of Minho, on the right bank, and two miles from the mouth of the Douro, in lat. 41° 9' N., long. 8° 37' W.; and is 195 miles north-north-east of Lisbon. Though possessing few imposing edifices, the town, seen from a distance with its irregular outline marked with many towers, its whitewashed houses gleaming among trees and terraced gardens, has a fine picturesque effect. Its picturesqueness, however, has been secured at the cost to a great extent of comfort, as many of its streets are narrow, dirty, and so steep as to be impassable for carriages. Of the old walls that surrounded the ancient town, remains are still to be seen. The principal street is the *Rua Nova dos Ingleses*, a spacious, handsome, modern thoroughfare, from which a good view of the Bishop's Palace, which seems to be hung high in the air, is obtained. Here is situated one of the finest edifices in O., the English Factory House, a building of white granite with a beautiful façade, and comprising on a magnificent scale all the appurtenances of a club-house, as ball-room, library, refreshment-room, &c. The houses in the *Rua Nova de S. João*, the most regular street in the city, are lofty, and are faced with

gaily painted and gilt balconies. Of the 11 squares, the greatest is the *Praça de S. Ovidio* on a height, the appearance of which is enhanced by beautiful buildings and a terrace, with a fine seaward view, planted with trees. On the high rocks, on the southern bank of the river, stands the convent of *da Serra*, which at one time was extraordinarily rich. The most beautiful of the convents was that of *S. Bento*, now converted into barracks. The cathedral, which must originally have been a noble edifice, but has been infamously modernised, stands near the Bishop's Palace. The *Torre dos Clerigos* (Tower of the Clergy), said to be the highest in Portugal, was built in 1748. Formerly, there were in all 80 convents and chapels in the city. Of existing institutions, there are four hospitals, and numerous educational and benevolent establishments. O. is the principal industrial seat in the country. It carries on manufactures of linen, silk, cotton, and woollen fabrics, cloth of gold, silk and cotton hosiery, lace, buttons, gold and silver wire, cutlery and hardware, excellent furniture, pottery, glass, leather, paper, hats, sails, and the articles required on ship-board. Royal tobacco and soap-works, two iron-foundries, and several sugar-refineries are also in operation. The entrance to the Douro is rendered highly dangerous by a shifting bar of sand; but yet the commercial traffic on the river is considerable. The exports of wine were larger in 1874 than in any former year, amounting to 301,810 hectolitres, of which seven-elevenths was shipped for England. O. has imported from England in a single year cotton goods to the value of £330,000, and woollen goods, £70,000. O. builds ships. In 1875 the port owned 137 ships of 38,540 tons. Pop. (1878) of O. 89,295; but with its four suburban districts, 103,346.

In ancient times, the site of O. was occupied by the harbour-town *Portus Cale*, afterwards *Porto Cale*, from which has been derived the name of the kingdom, Portugal. It was an important city during the supremacy of the Moors, was destroyed in 820 by Almanzor of Cordova, but was restored and peopled by a colony of Gascons and French in 999. It was famous for the strength of its fortifications during the middle ages, its walls being 3000 paces in circumference, 30 feet in height, and flanked with towers. From the 17th to the present century, O. has been the scene of an unusual number of popular insurrections. In 1808, it was taken by the French; but in the following year it was retaken by an Anglo-Portuguese force under Wellington. In 1832, Dom Pedro, the ex-emperor of Brasil, was unsuccessfully besieged for a year in this city by the forces of Dom Miguel.

OPOSSUM (*Didelphis*), a genus of *Marsupialia*, having ten cutting teeth in the upper jaw, and eight in the lower, one canine tooth on each side in each jaw, three compressed premolars, and four sharply-tuberculated molars on each side—fifty teeth in all; the tongue bristly; the tail long, prehensile, and in part scaly; the feet plantigrade; five toes on each foot, their claws long and sharp; but the inner toe of the right foot converted into a thumb, destitute of a claw, and opposable to the other digits; the muzzle long and pointed, the mouth very wide, the ears large and destitute of hair. The unwebbed feet and non-aquatic habits distinguish this genus from *Cheironectes* (q.v.), also belonging to the family *Didelphidae*. But the genus *Didelphis* itself is divided by some naturalists into several genera; and there are differences not unimportant, particularly in the well-developed pouch of some species, and the merely rudimentary pouch or abdominal folds of others. All the existing species are American, but fossil species are found in other parts of the world. The opossums were the first marsupial

animals known, and are noticed as very wonderful creatures by some of the earliest writers on America. Some of the smaller species much resemble rats and mice, except in their long and pointed muzzle; others greatly resemble shrews; the largest known species are scarcely equal in size to a large cat. It is in some of the smaller species that the pouch is rudimentary; all the larger species have a well-developed pouch, in which the young are carried, and to which, even after beginning to venture forth from it, they retreat on the approach of danger. The young of the species which have a merely rudimentary pouch, also remain attached to the nipple of the mother for a time; and afterwards for a time are carried on her back, intertwining their prehensile tails with hers, and clinging to the fur of her back.—The VIRGINIAN O. (*D. Virginiana*) is one of the largest species. It abounds in the warmer parts of North America, and

Virginian Opossum (*Didelphis Virginiana*).

its range extends considerably to the north of Virginia. Its form is robust, its head very large, its colour dull white; its fur long, fine, and woolly, thickly interspersed with longer coarse white hairs, except on the head and some of the upper parts, where the hair is short and close. The tail is not quite so long as the body. The Virginian O. lives much in forests and among the branches of trees, to which it usually retreats to devour its prey, twining its tail around a branch for security. Its food consists of small quadrupeds and reptiles, birds' eggs, and insects; also in part of fruits and the juicy stalks of plants. It often visits poultry-yards, and displays much cunning in its stealthy quest of prey; although otherwise it seems, like the other *Marsupialia*, to be very low in the scale of intelligence. It seeks to escape from enemies by running to the woods and ascending a tree; but if escape is impossible, it feigns death, and maintains the imposture in very trying circumstances, however it may be kicked and beaten; but the true state of the case may be ascertained by throwing it into water. The American word '*possuming*' makes a figurative application of this part of the natural history of the opossum. The female sometimes produces sixteen young at a birth; the young when born are blind, naked, and shapeless, and weigh scarcely more than a grain each; they do not begin to leave the pouch until they have attained about the size of a mouse. The female O. shews a very strong attachment to her young. The O. is very easily tamed, but its strong odour makes it an unpleasant pet. The flesh of the O. is said to be good. The hair is woven into garters and girdles by the Indian women.—Other species of O. are found in the more southern parts of America. Of these, one of the largest is the CRAB-EATING O. (*D. cancrivora*) of Guiana and Brazil; which is nearly as large as the Virginian O., lives chiefly in

marshy places, and feeds much on crabs. The smaller species are numerous in the tropical parts of America.—The name O. is often given in Australia to the Phalangiers (q. v.).

O'PELN, a town of Prussian Silesia, capital of the government district of the same name, on the Oder, 51 miles south-east of Breslau. Since 1816, when it was erected into an especial seat of government for Upper Silesia, the town has been much beautified both with new edifices and with parks and gardens. It contains four churches—one of which, Adelbert's Church, was founded in 995—an old castle on the island Pascheke in the channel of the Oder, a town-house, and theatre. Pop. (1880) 14,447, who carry on a considerable transit-trade in timber, zinc, lead, hardware, cattle, and wines; and manufacture ribbons, linen goods, leather, and pottery.

OPPOSITION, the party in either House of the British parliament who are opposed to the existing government, and who would probably come into power on its displacement. The existence of a fair and temperate opposition, keeping a watch over the acts of the ministry, is undeniably conducive to good government; while, on the other hand, the conduct of public affairs may be seriously embarrassed by an opposition whose proceedings are conducted in a factious or obstructive spirit. The name Opposition is not generally applied to a party, merely because opposed to the existing administration, if there is no likelihood of their succeeding to power on a change of government.

OPTIC NERVE. See EYE.

O'PTICAL ILLUSION. Of all the senses none is more deceptive than the sense of sight; it often deceives us as to the distance, size, shape, and colour of objects; it frequently makes them appear as if in situations where their existence is impossible; and often makes us think them movable when they are not so, and *vice versa*. An object appears to us as large or small, near or distant, according as the rays from its opposite borders meeting at the eye form a large or a small angle: when the angle is large, the object is either large or near; when small, the object must be small or distant. Practice alone enables us to decide whether an object of large apparent size is so on account of its real size, or of its proximity; and our decision is arrived at by a comparison of the object *in position*, with other common objects, such as trees, houses, &c., which may chance to be near it, and of which we have by experience come to form a correct idea. The same is, of course, true of apparently small objects. But when all means for comparison are removed, as when we see a distant object floating on an extensive sheet of water, or erect in an apparently boundless sandy plain, where no other object meets the eye, then our judgment is completely at fault. Imperfection in the acquired perceptions of sight, as it is called, produces many other illusions; it leads us to consider spherical solids at a distance as flat discs, and deceives us regarding the size of objects, by their colour; the sun appears larger than he would if illumined by a fainter light, and a man in a white habit seems larger than he would if he wore a dark dress. Illusions are also produced by external causes; and instances of this sort are given under MIRAGE, REFLECTION, and REFRACTION.

The property which the eye possesses of retaining an impression for a very brief, though sensible period of time (about one-quarter of a second), after the object which produced the impression has been removed, produces a third class of illusions. Common examples of this are the illumined circle formed by the rapid revolution of an ignited carbon

point, piece of red-hot iron, or other luminous body, and the fiery curve produced by a red-hot shot projected from a cannon.

Another form of illusion is produced to a person who is seated in a vehicle in motion, and it is very deceptive when the motion is so equable as not to be felt by the person himself. The illusion is most complete when the attention is riveted on an object several yards off; this object then appears as a centre round which all the other objects seem to revolve, those between the observer and the object moving backwards, and those beyond the object moving forwards. This illusion occurs on a large scale in the apparent motion of the heavenly bodies.

Other illusions arise from a disordered state of the organs of vision; such are the seeing of things double or movable (if they are not so), or of a colour different from the true one; the appearance as of insects crawling over a body at which the eye is directed, &c.

OPTICS is the science whose object is the investigation of the laws that regulate the phenomena of light and vision. The nature of light will be found treated of under **LIGHT**, and its various properties under **CHROMATICS**, **DIFFRACTION**, **INTERFERENCE**, **LENS**, **POLARISATION**, **REFLECTION**, **REFRACTION**, **SPECTRUM**, &c.; and we shall confine ourselves in this article to a historical sketch of the rise and progress of the science.

Optics, as a science, is entirely of modern growth, for though the Greeks and their disciples the Arabs had made some progress in mathematical optics, their knowledge was confined to the law of reflection and its more immediate consequences. Euclid, Aristotle, Archimedes, Hero, and Ptolemy were acquainted with the fact that light is transmitted in straight lines, but with the important exception of Aristotle, and some of his followers, the ancient philosophers believed that rays proceeded from the eye to the object, instead of in the contrary direction. Ptolemy was well acquainted with atmospheric refraction. Alhacen (1070) and Vitellio the Pole (1260) were almost the only cultivators of this science during the middle ages, and their additions to it were unimportant. The lens, though known from early antiquity, was not applied as an aid to defective eyesight till after the time of Roger Bacon. Jansen, Metius, and Galileo separately invented the telescope about the beginning of the 17th c.; and the last-mentioned philosopher, by its means, made various important astronomical discoveries. Kepler, a short time after, gave the true theory of the telescope, explained the method of finding the focal length of lenses, and applied it to find the magnifying power of the telescope, besides pointing out the mode of constructing an instrument better adapted for astronomical purposes than that of Galileo; he also made some useful experiments on the nature of colours, and shewed that images formed on the retina of the eye are inverted, a fact previously discovered by Maurolycus of Messina. From this period the science of optics steadily advanced, and its treasury of facts received numerous additions through the labours of De Dominis, Snell (the discoverer of the law of refraction in 1621), Descartes, Fermat, Barrow, Mariotte, and Boyle. Up to the time of Newton it was generally believed that colour was produced by refraction, but that philosopher shewed by a beautiful series of experiments that refraction only separates the colours already existing in white light. In his hands the theory and construction of the telescope underwent many valuable improvements, and in 1672 the description of his reflecting telescope was submitted to the Royal Society.

Gregory had constructed an instrument on similar principles some years before. About the same time, Grimaldi made his interesting series of experiments on the effects of diffraction, and noticed the remarkable fact of the interference of one pencil of light with the action of another. The complete theory of the rainbow, with an elegant analysis of the colours of thin plates, and the hypothesis concerning the nature and propagation of light, now known as the 'corpuscular' theory, completed Newton's contributions to the science. The important services of the ingenious but eccentric Hooke cannot be easily stated in such a brief abstract, as he discovered a little of everything, completed nothing, and occupied himself to a large extent in combating faulty points in the theories of his contemporaries. It must not, however, be forgotten that he has as much right as Huyghens to the credit of originating the undulatory theory, which is the favourite one at present. The double refraction of Iceland spar was discovered (1669) by Bartholin, and fully explained in 1690 by Huyghens, the propounder of the undulatory theory, who also aided the progress of mathematical optics to a considerable extent. The velocity of light was discovered by Römer (1675), and in 1720 the aberration of the fixed stars and its cause were made known by Bradley, who likewise determined with accuracy the amount of atmospheric refraction. Bouguer, Porterfield, Euler, and Lambert rendered essential service to physical optics; the same was done for the mathematical theory by Dollond (the inventor of the achromatic telescope), Clairaut, Dalmont, Boscovich, &c.; while in later times the experiments of Delaval on the colours produced by reflection and refraction; the discussion of the phenomena arising from unusual reflection or refraction, carried on by Vince, Wollaston, Biot, Monge, and others; the discovery of polarisation of light by Malus (1808), and its investigation by Brewster, Biot, and Seebeck; of depolarisation by Arago (1811), and of the optical properties as connected with the axes of crystals (1818) by Brewster; and the explanation of these and other optical phenomena, in accordance with the undulatory hypothesis by Young—the discoverer of the *Interference* (q. v.) of rays—and Fresnel, went far to give optics a width of scope and symmetry which is possessed by few other sciences. The development of the undulatory theory and of optical science generally has been carried on in the present century by Lloyd, Airy, Cauchy, and others; and more recently important discoveries in connection with the physical modifications and chemical properties of light have been made (the latter chiefly, as far as the spectrum is concerned, by Kirchhoff), for a notice of which, and other discoveries, see **PHOTOGRAPHY**, **SPECTRUM**, and other articles.

OPTIMISM (Lat. *optimus*, best), the name given to the doctrine of those philosophers and divines who hold that the existing order of things, whatever may be its seeming imperfections of detail, is nevertheless, as a whole, the most perfect or the best which could have been created, or which it is possible to conceive. Some of the advocates of optimism content themselves with maintaining the absolute position, that although God was not by any means bound to create the most perfect order of things, yet the existing order is *de facto* the best; others contend, in addition, that the perfection and wisdom of Almighty God necessarily require that His creation should be the most perfect which it is possible to conceive. The philosophical discussions of which this controversy is the development are as old as philosophy itself,

and form the groundwork of all the systems, physical as well as moral, whether of the Oriental or of the Greek philosophy; of Dualism, Parsism, and of the Christian Gnosticism and Manichæism in the east; and in the west, of the Ionian, the Eleatic, the Atomistic; no less than of the later and more familiar, Stoic, Peripatetic, and Platonistic Schools. In the philosophical writings of the fathers, of Origen, Clement of Alexandria, and above all of Augustine, the problem of the seeming mixture of good and evil in the world is the great subject of inquiry, and through all the subtleties of the medieval schools it continued to hold an important and prominent place. But the full development of the optimistic theory as a philosophical system was reserved for the celebrated Leibnitz (q. v.). It forms the subject of his most elaborate work, entitled *Theodicea*, the main thesis of which may be briefly stated to be—that among all the systems which presented themselves to the infinite intelligence of God, as possible, God selected and created, in the existing universe, the best and most perfect, physically as well as morally. The *Theodicea*, published in 1700, was designed to meet the sceptical theories of Bayle, by shewing not only that the existence of evil, moral and physical, is not incompatible with the general perfection of the created universe, but that God, as all-wise, all-powerful, and all-perfect, has chosen out of all possible creations the best and most perfect; that had another more perfect creation been present to the divine intelligence, God's wisdom would have required of Him to select it; and that if another, even equally perfect, had been possible, there would not have been any sufficient determining motive for the creation of the present world. The details of the controversial part of the system would be out of place in this work. It will be enough to say that the existence of evil, both moral and physical, is explained as a necessary consequence of the finiteness of created beings; and it is contended that in the balance of good and evil in the existing constitution of things, the preponderance of the former is greater than in any other conceivable creation. The great argument of the optimists is the following: If the present universe be not the best that is possible, it must be either because God did not know of the (supposed) better universe, or because God was not able to create that better one, or was not willing to create it. Now every one of these hypotheses is irreconcilable with the attributes of God: the first, with His omniscience; the second, with His omnipotence; and the third, with His goodness. See Leibnitz, *Theodicea*; Baummeister's *Historia de Mundo Optimo*. The view of the universe diametrically opposed to O. is Pessimism (*pessimus*, worst), and has of late been frequently maintained: see Sully's *Pessimism* (1877).

OPUNTIA. See PRICKLY PEAR.

OPUS OPERANTIS (Lat. literally 'the work of the worker'), a well-known theological phrase, intended to convey that the effect of a particular ministration or rite is primarily and directly due, not to the rite itself (*opus*), but to the dispositions of the recipient (*operans*). Thus, in the act of kissing or praying before a crucifix, of sprinkling one's self with holy water, of telling the prayers of the rosary upon blessed beads, the fervour and personal piety of the suppliant, and not the material object of the religious use, is held to be the efficient cause of the grace which is thereby imparted. The term is used chiefly by writers of the Roman Catholic schools, in whose system, however, the sacramental rites are held to differ from all others in this respect. See OPUS OPERATUM.

OPUS OPERATUM (Lat. literally 'the work wrought') is the phrase employed in the Catholic theological schools to describe the manner of the supposed operation of the sacramental rites in the production of Grace (q. v.). It is intended to imply that the ministration of the rite (*opus*) is in itself, through the institution of Christ, an efficient cause of grace, and that, although its operation is not infallible, but requires and presupposes certain dispositions on the part of the recipient, yet these dispositions are but *conditiones sine qua non*, and do not of themselves produce the grace; and hence, when the sacraments are administered to dying persons in a state of apparent insensibility, this is done in the hope and on the presumption that the dying person may, though seemingly unconscious, be nevertheless really disposed to receive the sacrament; but it is by no means held that if these dispositions be wanting, the sacrament will itself justify him. It is a mistake, therefore, to suppose, as is often done in popular controversy, that Catholics ascribe to the sacramental rites such magical or talismanic power that they can sanctify even an unrepentant sinner. Their efficacious operation presupposes as conditions the repentance and other moral dispositions of the recipient, although the grace which they give is due, not to these dispositions, but to the sacraments as received with the dispositions.

OR, in Heraldry, the metal gold, represented in heraldic engravings by an unlimited number of dots.

Or.

O'RACHE (*Atriplex*), a genus of plants of the natural order *Chenopodiaceæ*, having male, female, and hermaphrodite flowers; the male and hermaphrodite flowers with a 3-5-partite calyx, and 3-5 stamens; the female flowers with a compressed and 2-lobed or 2-partite calyx. The species are numerous. Some of them are of frequent occurrence in waste places, and as weeds in gardens in Britain and throughout Europe. GARDEN O. (*A. hortensis*), also called MOUNTAIN SPINACH, was formerly much

Orache patula.

cultivated in England, and is still cultivated in some parts of Europe as a substitute for spinach. It is a native of Tartary, an annual, with a stem about three feet high, and cordate-triangular leaves, which are thick and glaucous, and have a

slightly acid flavour. The leaves are sometimes greenish, sometimes reddish, which is the case also in other species, and the flowers resemble the leaves in colour.—The leaves of the Sea O. (*A. littoralis*), a native of the British coasts, are used in the same manner, and those of the common garden-weeds, *A. patula* and *A. angustifolia*, are excellent substitutes for spinach.—It is mentioned in Remy and Brencley's *Journey to the Salt Lake City*, that an orache, with pale pink leaves and a salt taste, is cultivated by the Indians on the Humboldt River for its seed, which resembles that of Quinoa (q. v.), and is used like it for making porridge and bread.

O'RA'CLE, the response delivered by a deity or supernatural being to a worshipper or inquirer; also the place where the response was delivered. These responses were supposed to be given by a certain divine affluens, either through means of mankind, as in the oracles of the Pythia, and the dreams of the worshipper in the temples; or by its effect on certain objects, as the tinkling of the caldrons at Dodona, the rustling of the sacred laurel, the murmuring of the streams; or by the actions of sacred animals, as exemplified in the Apis or sacred bull of Memphis, and the feeding of holy chickens of the Romans. This arose, in fact, from the idea that the deity signified his intentions to men by signs or inspirations, which, however, had always to be interpreted to the inquirer by the priesthood. Such responses were, however, closely allied to augury, which differed in this respect that auguries could be taken anywhere, while the oracular spots were defined and limited. Oracle dates from the highest antiquity, and flourished in the most remote ages, and gradually declined with the increasing knowledge of mankind. Among the Egyptians all the temples were probably oracular, although only a few are mentioned by Herodotus, as the oracle of Latona, in the city of Buto; those of Hercules, Mars, Thebes, and Meroe. In the hieroglyphic texts the gods speak constantly in an oracular manner, and their consultation by the Pharaohs is occasionally mentioned. In later days the most renowned of these oracles was that of Ammon, in the Oasis (q. v.), where oracular responses were rendered either by the shaking of the statue of the god, or by his appearance in a certain manner. Oracles were also used by the Hebrews, as in the consultation of the Urim and Thummim by the high priest, and the unlawful use of Teraphims, and consultations of the gods of Phœnicia and Samaria. The Hebrew oracles were by word of mouth, as the speech of God to Moses, dreams, visions, and prophetic denunciations; besides which, there were oracles in Phœnicia, as that of Balzebug and others of the Baalim. They were also in use throughout Babylonia and Chaldaea, where the responses were delivered by dreams given to the priestesses, who slept alone in the temples as concubines of the gods. So numerous were they in the ancient world, that 300 are said to have been in existence.

The most celebrated oracles of Asia Minor were those of Telmissus in Caria or Lycia, which gave responses by dreams, and that of Apollo at Patara; but the Grecian oracles enjoyed the highest reputation for truthfulness, and the most celebrated of these were the Dodonean, the Delphic, and that of Trophonius and Amphiaraus. The Dodonean (see DODONA) was the only oracle in Greece which was given by Jupiter; the others were either those of Apollo, or of certain soothsayers, to whom that god had imparted the gift of prophecy, or of other gods. The most renowned of all was the Delphic oracle (see DELPHI), and was Panhellenic or open to all Greece, consulted for public purposes, and occupying

a position resembling in some respects that of the papacy in the middle ages in Europe. The name of the first priestess who gave oracles was Phemonoe. The consultations were generally in the Delphic month, *Byzios* or April, and once a day on other months; and the precedence of consulting the oracle was determined by lot, but rich presents obtained for Croesus and the Lydians the privilege of first consultation. Sacrifices were offered by the inquirers, who walked with laurel crowns on their heads, and delivered in sealed questions; the response was deemed infallible, and was usually dictated by justice, sound sense, and reason, till the growing political importance of the shrine rendered the guardians of it fearful to offend, when they framed the answers in ambiguous terms, or allowed the influence of gold and presents to corrupt the inspirations. The other oracles of Apollo were at Aba in Phocis; at Ptoon, where a man prophesied, which was destroyed in the days of Alexander the Great; and at Iamanus, south of Thebes, Hysia, Tegyra, and Eutressia. In Asia Minor the most celebrated was that of Branchidæ, close to Miletus, celebrated in Egypt, Gryneum, and Delos. Besides that of Dodona, Zeus had another at Olympia; and those of various other deities existed elsewhere. A secondary class of oracles of heroic or prophetic persons existed in Greece, the two most celebrated of which were those of Amphiaraus and Trophonius. The first mentioned was one of the five great oracles in the days of Croesus, and was situate at Oropus, in Attica, being the shrine of a deified magician, or interpreter of dreams, having a fountain close to it. Those who consulted it, fasted a whole day, abstained from wine, sacrificed a ram to Amphiaraus, and slept on the skin in the temple, where their destiny was revealed by dreams. That of Trophonius was at Lebadea, in Boeotia, and owed its origin to a deified seer. It was given in a cave, into which the votary descended, bathed, and anointed, holding a honeyed cake. He obtained a knowledge of futurity by what he saw or heard, and returned dejected from the cavern. Then, seated upon the seat of Mnemosyne, he gave an account of what he had heard, and conducted to the chapel of Good Fortune or Good Genius, recovered his usual composure. There were some other oracles of minor importance. Besides these oracles, written ones existed of the prophecies of celebrated seers, as Bacis and Musæus, which were collected by the Pisistratidæ, and kept in the Acropolis of Athens. Those of the Enolus, Panolmus, and Lycus were also celebrated. Others of the Sibyls or prophetic women, daughters of Zeus and Lamia, were popular, and at a later period (see SIBYLS), Athenais and others, prophesied in the days of the Seleucidæ. Amongst the oriental nations, as the Arabs and others, divination was and is extensively practised, but there are no set oracles. The Celtic Druids are said to have delivered responses, and the oracle of the Celtic god Belenus or Abelio, in the Isle de Sein, was celebrated. Herodot. *Hist.* v. 83, viii. 82; Curtius, iv. 7; Hare, *Ancient Greece*, (12mo, Lond. 1836, p. 141); Bos, *Antiquities of Greece* (1823, p. 31).

ORA'N (Arab. *Waran*), a thriving municipal town and seaport of Algeria, capital of the province of the same name, stands at the inner extremity of the Gulf of Oran, 220 miles west-south-west of Algiers. The province of Oran, sometimes called the province of the West, from the fact of its forming the western frontier of the country, is bounded on the N. by the Mediterranean, on the E. by the province of Algiers, on the W. by the empire of Morocco, and on the S. by the desert. Area about 100,000 sq. miles, of which 13,514 belong to the Tell (q. v.),

and a large portion to the Sahara. Pop. (1881) 767,322, four-fifths of whom were Arabs. The town of O. is the seat of the government offices—the prefecture, the civil, criminal, commercial tribunals, &c. It also contains a college, primary and native schools, Protestant and other churches; synagogues; mosques; a branch of the bank of Algeria; exchange, post, and telegraph offices; three great barracks, St Philippe, le Château-Neuf, and le Château-Vieux; a military hospital, with accommodation for 1400 beds (an immense new building, which overtops all surrounding edifices), and various splendidly appointed magazines and government stores. The town, which is girt by walls, and defended by strongly armed forts, is seated at the foot of a high mountain, crowned by the forts Santa-Cruz and Saint-Gregoire. The port does not offer safe anchorage; although it has been much improved within recent years. Large vessels, however, have still to find shelter in the roadstead of Mers-el-Kebir, three miles distant. The streets and promenades of O. are generally spacious, the houses elegant and airy. The principal edifices are the Château-Neuf, the residence of the general of division; the Hôtel de la Préfecture; the great mosque de la Rue Philippe; the Catholic church; and the barracks. Pop. of commune, comprising the three suburbs, Mers-el-Kebir, La Senia, and Ain-el-Turk (1881) 58,530. The country in the vicinity is bare and arid, although the land is not sterile. To the south of the town the country is uncultivated; but towards the south-east, highly cultivated lands are seen. In the vicinity there are a great many farms, cultivated with the greatest care, and most of them furnished with buildings necessary to their efficiency. Cattle are reared, and grain, tobacco, and cotton are grown. The vine already covers large tracts of land, and its cultivation is annually extending. It is cultivated with the most complete success, and the wines are of good quality.

Besides the commune of O., there are in the province the communes of Sidi-bel-Abbès (q. v.), of Mostaganem (pop. 13,000), of Mascara (pop. 6000), and of Tlemcen (q. v.).

The town of O. was built by the Moors. It was taken by the Spaniards in 1509, by the Turks in 1708, and again by the Spaniards in 1732. In 1791, it was destroyed by an earthquake, and shortly after it was altogether abandoned by the Spaniards. O. was taken by the French in 1831, has since remained in their hands, and has by them been developed into a large and prosperous town. Vessels with an aggregate tonnage of 65,000 tons enter and clear the port yearly. The annual imports amount to about £1,307,700, and the exports to £260,990. A bishopric was established at O. in the year 1867.

ORANG, or ORANG-OUTANG (*Simia satyrus*, or *Pithecus satyrus*, or *P. Abellii*), a species of ape found in the forests of Malacca, Cochinchina, and some of the islands of that part of the world. The name is sometimes extended in signification, so as to include all the species of the restricted genus *Simia* or *Pithecus*, a genus which exists only in the south-east of Asia and the Eastern Archipelago; and was also till of late extended even to the African apes now forming the genus *Troglodytes*, the species which is the subject of this article being distinctively called the RED O., when it and the Chimpanzee were the only *anthropoid* apes known. The name orang is Malayan, and signifies *man* or *rational being*; outang signifies *wild*, or *of the woods*. The genus *Simia* or *Pithecus* differs from *Troglodytes* (the Chimpanzee and Gorilla) in the more lengthened muzzle—the lower part of the face projecting

suddenly and remarkably; in the very large canine teeth; in the great breadth of the central incisors; and in the great length of the arms, which are so long that the fingers can touch the ground when the animal stands erect. The ears are also small, and lie close to the head. The eyes are close together; the nose is little elevated; the lips are scarcely visible when the mouth is shut. The apes of this genus are arboreal in their habits, and not

Orang-Outang (*Simia satyrus*).

gregarious. They are ill adapted for walking on the ground, and in a wild state probably almost never assume an erect posture, and although they can be taught to do it in confinement, they maintain it with difficulty, and only when standing still; even then often seeking to adjust the balance of the body by raising the arms above and behind the head. In climbing and swinging among the branches of trees, the hands of the hinder extremities are used as readily as those of the anterior, and the great length of the arms is useful in enabling them to take hold of distant branches. The fingers of all the extremities are very long.

Some of the most important distinctions between the anatomy of the anthropoid apes and that of man, are noticed in the article CHIMPANZEE. The O. and its congeners are regarded as differing more widely from man in their anatomical characters than the chimpanzee and gorilla; although the number of ribs is the same as in man, and there are a few other particulars in which the O. more nearly resembles a human being than any of the African apes do. The projecting muzzle is much less notable in the young than in the adult O., and the aspect of the adult males is further rendered hideous by great callosities on the cheeks. In the adult state, the ridges of the skull also greatly increase in thickness and prominence.

The species of this genus exhibit in a much greater degree than those of *Troglodytes* an anatomical character common also to many other apes and monkeys, a pouch in the throat, opening from the windpipe, and capable of being dilated with air at the pleasure of the animal. In the O., it branches into several subordinate pouches, which are situated among the muscles of the throat. The use of this organ is not known. It does not appear to have any connection with the voice; and has been supposed, not very probably, to be of some service in leaping, by diminishing the specific gravity of the animal.

There are at least two other species of the genus besides that best known as the O., one of these being the great Pongo (q. v.) of Borneo (*S.* or *P. Wombii*), and the other (*S.* or *P. morio*), also a native of Borneo, of comparatively small size. The natural history of these apes has not been thoroughly investigated; and, until recently, it was supposed that the species first known might be identical with the great ape believed to exist in the woods, and that the differences of size and other characters might depend merely on age. The O. is about three feet in length from the heel to the crown of the head. It is covered with brownish-red hair, which, on the back and arms, is five or six inches long, but very short on the backs of the hands and feet. There is little hair on the face, and none on the palms of the hands. When taken young, it is easily tamed, and becomes sufficiently familiar. It displays considerable sagacity, and some playfulness and love of mischief, but is not so frolicsome as many of the monkey tribe. Young specimens have sometimes been brought to Europe, but none have lived long. The temper is believed to change very much to the worse, when the animal reaches maturity.

ORANGE, the name of one or more species of *Citrus* (q. v.), of which the fruit is much prized. Botanists generally regard all the oranges as of one species, *Citrus aurantium*, but some follow Risso in making the Sweet O., the Bitter O., the Bergamot O., &c., distinct species. The wild state of the O. is not certainly known, although its characters may be pretty confidently inferred from the degeneration of cultivated varieties; and no cultivated plant shews a greater liability to degenerate, so that seedling oranges are almost always worthless. Nor is its native country more certain, although there is much reason to believe that all the kinds have spread over the world from the warmer central and eastern parts of Asia. It has been alleged that the O. is a native of North America, near the Gulf of Mexico; but the probability rather seems to be that it has been introduced, and has become naturalised.

The COMMON O., or SWEET O. (*Citrus aurantium* of Risso), is an evergreen tree of moderate size, with greenish-brown bark; the leaves oblong, acute, sometimes minutely serrated, the leaf-stalks more or less winged, the flowers white, the fruit roundish, the oil-cysts of the rind convex, the juice sweet and acid. It is cultivated in almost every part of the world of which the climate is warm enough, but succeeds best in the warmer temperate or sub-tropical climates, as in the south of Europe, where it is very extensively cultivated, as far north as the south of France. The O. does not seem to have been known to the Greeks or Romans, but was probably brought to Europe by the Moors, and is supposed to have been introduced into Italy so recently as the 14th c., fully 1000 years after the citron. In the north of Italy, oranges are sometimes grown in conservatories, but often in the open air, except during winter, when they are covered with temporary houses of boards. In the south of England, they are sometimes in like manner grown in the open air, with a shelter of boards or matting in winter, but trained against a south wall; attaining a large size, and yielding good fruit. The abundant importation of the fruit, however, renders the cultivation of the O. in Britain unnecessary; and, in general, only small plants are to be seen in green-houses or conservatories, as mere objects of interest. In former times, when the evergreen shrubs in cultivation were much fewer than now, O. trees were very commonly cultivated in pots, both in green-houses and in windows of apartments in Britain, as is still the case in the northern parts of Germany. The O. loves a rich soil, and succeeds well in a strong clay.

There are many varieties in cultivation, which are perpetuated by grafting upon seedling O. stocks, and by layers.

Of the varieties of the Sweet O., perhaps the most deserving of notice are the PORTUGAL or LISBON O., the most common of all, having the fruit generally round or nearly so, and a thick rind; the CHINA O., said to have been brought by the Portuguese from China, and now much cultivated in the south of Europe, having a smooth thin rind and very abundant juice; the MALTESE or BLOOD O., remarkable for the blood-red colour of its pulp; the Egg O., having fruit of an oval shape; and the TANGERINE O., having a small flat fruit, with a pleasant odour and finely flavoured pulp. The St MICHAEL'S O. appears to be a subvariety of the China Orange. The MAJORCA O. is seedless, resembling in this certain cultivated varieties of other fruits.

The BITTER O., SEVILLE O., or BIGARADE (*Citrus vulgaris*, or *C. bigaradia*), is distinguished from the Sweet O. by the more truly elliptical leaves, the acid and bitter juice of the fruit, and the concave oil-cysts of its rind. Its branches are also spiny, which is rarely the case with the Sweet Orange. The varieties in cultivation are numerous. The Bitter O. was extensively cultivated by the Moors in Spain, probably for medicinal purposes. The rind is more bitter than that of the Sweet O., and is used as a stomachic and tonic. Its chief use, however, is for flavouring puddings, cakes, &c., and for making marmalade.

The BERGAMOT O. (*C. Bergamia*) is noticed in a separate article.

The MANDARIN O., or CLOVE O. (*C. nobilis*), recently introduced from China, has fruit much broader than long, with a thick rind, very loosely attached to the flesh, so that there is often a space between them. The leaves are smaller than those of any other kind of orange.

O. leaves are feebly bitter, and contain a fragrant volatile oil, which is obtained by distilling them with water, and is known in the shops as *Esence de Petit Grain*. O. flowers yield, when distilled with water, a fragrant volatile oil, called *Oil of Neroli*, which is used in making *Eau de Cologne*, and for other purposes of perfumery. The flowers both of the Sweet O. and of the Bitter O. yield it, but those of the Bitter O. are preferred. Dried O. flowers, to be distilled for this oil, are an article of export from the south of Europe. They are packed in barrels, and mixed with salt. The dried flowers have a yellowish colour; the fresh flowers are white and very fragrant. The use of them as an ornament in the head-dress of brides is common throughout great part of the world.—The small green oranges, from the size of a pea to the size of a cherry, which fall from the trees, both of the Sweet O. and the Bitter O., when the crop is too great to be brought to maturity, are carefully gathered and dried, and are the O. berries of the shops. They are used in making Curaçoa. They also yield a fragrant oil on distillation, the original *essence de petit grain*; and they are smoothed in a turning-lathe, and employed as *issue pease*; not readily acquiring a fetid odour, as pease do when employed for this purpose.—The dried and candied rind of the ripe Bitter O., well known as *Orange-peel*, is used as a stomachic, and very largely for flavouring puddings and articles of confectionary. The rind of the Sweet O. is sometimes employed in the same way, but is inferior. A fragrant essential oil is obtained from the rind of the O. by distillation with water, and is sold by perfumers as *Oil of Sweet O.*, or *Oil of Bitter O.*, according as it is obtained from the one or the other, although the two kinds of oil are very similar. The rind of the O. is used in the preparation of a fine

liqueur called *O. Rosoglio*, which is an article of export from some parts of Italy. Besides the use of the Sweet O. as a dessert fruit, and as a refrigerant in cases of sickness, its juice is extensively used as a refrigerant beverage, and is particularly valuable in febrile and inflammatory complaints.

O. trees are often extremely fruitful, so that a tree twenty feet high, and occupying a space of little more than twelve feet in diameter, sometimes yields from 3000 to 4000 oranges in a year. The O. tree attains an age of at least 100 to 150 years. Young trees are less productive than old ones, and the fruit is also less juicy, has a thicker rind, and more numerous seeds.

The wood of the O. tree is yellowish white and close-grained. It is used for inlaying and for turnery.

The fruit of the O. tree is of great commercial importance, for not only is it one of the most delicious and wholesome of fruits, but fortunately it is also the most easily kept and carried from place to place. No fresh fruit possesses in the same degree as the O., and its congeners, the lemon, citron, lime, &c., the property of being easily packed in boxes, when nearly ripe, and being in that state able to stand the close confinement of a ship's hold during a voyage of two or three weeks. The O. is much cultivated in the Azores, Malta, Sicily, Spain, and Portugal, and it is from these localities that Britain receives its supply. Those from St Michael's, one of the Azores, and from Malta, are the best varieties in our markets; but the *Mandarin O.* of China and the *Naval O.* of South America are much superior. The latter occasionally reach this country in small quantities from Brazil; they are nearly double the size of the ordinary O., and have a peculiar navel-like formation on the top of the fruit, which is somewhat oval in shape. The very small O., now often seen in our shops, with an extremely aromatic rind, is the *Tangerine O.*, of which there are two varieties—the greater and lesser. The latter is hardly an inch in diameter, but the flesh is sweet, and the rind deliciously fragrant. The larger variety is about half the size of a common O., and is the one generally seen.

The Bitter O. is called the *Seville O.* in consequence of large plantations, which the Moors planted round the city of Seville, having for a long time furnished the chief part of those used in this country; but it also has several varieties, which are all remarkable for the bitterness of the rind, and the not very pleasant sharpness of the juice. Their chief use is for making the well-known confection called *Orange Marmalade*, and for this the true *Large-fruited* variety is the best, but it is now somewhat scarce.

Oranges, when gathered for export, must not be quite ripe; those fully formed, and with the colour just turning from green to yellow, are chosen. Each is wrapped in a piece of paper, or in the husk of Indian corn, and they are packed in boxes and half-boxes, chests and half-chests—the former are the Sicilian packages, the latter are St Michael's, Spanish, and Portuguese. A box contains about 250, a chest about 1000 oranges; and the price ranges from 15s. to 30s. per box, and from 30s. to 50s. a chest. The crop begins to arrive early in November, and the ships continue to bring them until the spring. The quantity consumed in Great Britain alone is enormous; and since the duty was removed, has reached nearly two millions of bushels annually.

Orange-peel, or the rind of the O., is used both in medicine and in confectionary—for the former purpose, it is merely cut into long strips, and dried; for the latter, it is carefully separated, either in

halves or quarters, from the fruit, and after lying in salt-water for a time, is washed in clear water, and then boiled in syrup of sugar, or candied, and is sold extensively as candied peel. The rinds of the citron and lemon are treated in the same manner.

ORANGE (the ancient *Araucio*), an ill-built, decaying, and dirty, but also an interesting town of France, in the department of Vaucluse, stands in a beautiful plain on the left bank of the Aigue, 16 miles by railway north of Avignon. Its chief manufactures are silks, muslins, serges, &c.; and there are numerous oilworks, dyeworks, and tanneries. It carries on a considerable trade in wine, spirits, oils, truffles, saffron, honey, madder, and essences. Pop. 6000.

O. was the capital of a small independent principality of the same name (now comprised in the department of Vaucluse), which was ruled by its own sovereigns from the 11th to the 16th century. The last of these sovereigns, Philibert de Chalons, died in 1531, without issue. His sister, however, had married a Count of Nassau, and to that House the estates and titles passed. The Count of Nassau who obtained the principality of O. was William, the father of William I., the Stadtholder of the United Provinces (see WILLIAM, PRINCE OF O.). William III., Prince of Orange and king of England, having died in 1702 without issue, there began a long-continued controversy as to the succession between Frederick I. of Prussia (as grandson of one of the last princes of O.), the representative of the older branch of the house of Nassau (q.v.), and the head of the younger line. At the peace of Utrecht (1713) the king of Prussia took the settlement into his own hands, so far as the territory of O. was concerned, by making it over, for certain equivalents, to the king of France. The title, Prince of O., remained with the younger Nassau line, afterwards kings of the Netherlands, and is now borne by the heir-presumptive to the Dutch throne.

In the vicinity of O. are several notable Roman remains. The triumphal arch, 60 feet high, is celebrated for the beauty of its architecture, and for its richly sculptured *bassi-relievi*. Of the theatre, the remains are sufficiently entire to give a good idea of the arrangements of this institution as it existed among the Romans.

OR'ANGE, a township in New Jersey, U. S., four miles north-west of Newark, containing three villages, Orange, North Orange, and South Orange. Orange Mountain commands a noble view of New York City and Bay, and its slope is laid out in beautiful parks, and ornamented with villas. It is the site of a Roman Catholic College and a Water-cure. Pop. (1870) 9348; (1880) 13,206.

ORANGE COLOURS, for painters' use, are various shades of alteration produced on chrome yellow (see YELLOW), by acting on it either with diacetate of lead or a weak alkaline lye, both of which redden the otherwise pure yellow, and give it an orange tint.—For dyers, a beautiful orange red is obtained from safflower; and orange yellows are made by mixing, in proper proportions, any of the red with the yellow dyes.

ORANGE RIVER. See GARIEP.

ORANGE RIVER FREE STATE. The Orange River Free State is the name assumed by the republic of Dutch boers, who, after retiring from Natal when declared a British colony, established themselves in the country lying between the two great branches of the Orange River, the *Ky Gariep* and the *Gariep*, known to the colonists as the *Vaal* and *Orange Rivers*, and separated from the coast

region by the great chain of the Quathlamba, Maluti, and Drachenberg mountains.

The Orange River Free State forms a sort of connecting-link between the Cape Colony, the Transvaal, and Natal. It consists chiefly of vast undulating plains, which slope down from the Maluti Mountains to the Vaal River, dotted over with rocky hills, called 'Koppies'; but in the north, hundreds of square miles are found with hardly a break on the horizon. It comprises an area of above 60,000 square miles; pop. at the first census (1880) 133,518 (of whom 61,002 were whites).

When the emigrant Dutch boers took possession of this country, it was inhabited by different tribes of Betjounas and Corannas, all of whom have been dispersed or subdued, including the powerful Basuto tribe, under the late chief Mosheah. The country is very rich in minerals: precious stones occur; coal is found everywhere, and iron, tin, copper, and lead are plentiful; besides plumbago, alum, saltpetre, ochre, and useful earths.

All the rivers of this region are affluents of either of the branches of the Gariep; amongst them may be named the Modder, Valsch, Great and Little Vet, which run into the Ky Gariep or Vaal River, and the Caledon, a considerable stream, which joins the Orange River after draining the Basuto country.

This region is a vast plateau, rising from 3000 to 5000 feet above the sea-level, with very little wood, except along the lines of the water-courses that traverse it. Travellers crossing this state from the Cape Colony to Natal arrive at the top of the passes leading to the latter colony without a mountain being in sight, and then find themselves suddenly on the edge of an immense mountain-chain, with the coast region several thousand feet below them, extending to the Indian Ocean. Immense herds of the larger antelopes formerly tenanted these vast plains, and are vividly described by Captain Harris, Gordon Cumming, and others; they are now fast disappearing. The diamond-fields recently discovered lie partly in this state, partly in Griqualand West, now British territory.

The land in the Free State is very fertile. The difference of temperature in various parts of it renders it possible to raise tropical and sub-tropical products, coffee, sugar, rice, and cotton, in some parts; while hemp, flax, and the vegetables of northern latitudes grow freely elsewhere. Tobacco and maize are largely cultivated, and fruits can be had all the year round. The climate of the state is very healthy; and that of the uplands, considering the latitude, is wonderfully cool. The houses of most of the inhabitants are little more than strongly built mud huts, very sparsely furnished.

The capital, Bloemfontein, is the only town of considerable size, and contained, in 1881, 2567 inhabitants. The other villages or small towns are on the increase. The Dutch Reformed Church has about 20 congregations; the Anglican, Wesleyan, Lutheran, and Roman Catholic Churches are also represented. There are 13 administrative districts in the state. The public income in 1879-80 was stated at £107,074, the expenditure at £104,719.

The history of the country forming the Free State may be summed up in a few words. Captain Harris describes it, before 1836, as a howling wilderness, inhabited by wandering hordes of Bushmen and broken tribes of Betjounas and Zulu refugees from the armies of the great Zulu tyrants, Chaka, Dingaan, and Maselikutse. After the Kaffir war of 1836-1838, a spirit of dissatisfaction arising in the minds of many of the frontier boers, an extensive emigration took place along the north-east frontier of the Cape Colony; the majority of the emigrants, however, having Natal as their ultimate goal.

However, after the British government had declared it an English colony in 1843, the boers again fell back on this region, and by degrees declaring the independence of the British crown, and forming sort of Alsatia on our very borders, after some opposition, and one or two conflicts with our troops, the country was annexed by Sir H. Smith to the British empire, under the name of the Orange River Sovereignty; and continued so until 1854, when Sir G. Clerk formally gave it up, and allowed the inhabitants to form a government according to their own wishes. The government is now in the hands of a president, freely elected by the landroest or heemraden in the several districts; while the volksraad, or peoples' council, exercise legislative functions. This state labours under the very serious disadvantage of being, like the kingdom of Bohemia, entirely inland, and has no port on the ocean, which customs dues can be collected; thus throwing the whole of the expense of government on local taxation.

About the year 1862, a large number of Griquas, a tribe of Bastard Hottentots, who inhabited the south part of the state—sold their farms to the Free State government, and migrated in a body to the coast side of the mountains in Independent Kaffraria, occupying a large tract of country then known by the name of No Man's Land.

In 1866, a treaty was concluded with Mosheah, chief of the Basutos, by which a portion of the territory known as Basuto Land was ceded to the O. R. F. S. The boundaries agreed on by the treaty were, however, somewhat modified by the governor of Cape Colony in 1869—a significant fact.

The Dutch boers profess the Dutch Reformed faith, and speak a dialect of Dutch, corrupted with Hottentot and English words. They marry young, and keep up, to some extent, nomadic habits. The roads and internal communication are good. Lime and timber are rather scarce, but building stone and thatch abundant. Woolled sheep have increased amazingly within the last few years; as farms that ten years ago would hardly fetch £5 now sell at from £2000 to £3000. The value of its ports is about £500,000 a year; of exports, £1,000,000.

O'RANGEMAN, one of the unhappy party designations which contributed for nearly a century to create and keep alive religious and political divisions of the worst character throughout the British empire, but especially in Ireland. The Orangeman organisation had its origin in the animosities which had subsisted between Protestants and Catholics in Ireland from the Reformation downwards, which reached their full development after the Revolution of 1688, and the wholesale confiscation of Catholic property by which that event was followed. From that time, the Catholics of Ireland may be said legally to have lost all social, political and religious status in Ireland. Some attempts which were made in the latter part of the 18th century to ameliorate their condition, excited, especially in the north, the alarm of the Protestant party, who regarded the traditional 'Protestant ascendancy' as endangered. Acts of violence became of frequent occurrence, and, as commonly happens, combinations for aggressive and defensive purposes were formed, not alone by the Protestants, but also by their Catholic antagonists. The members of Protestant associations appear at first to have been known by the name of 'Peep-of-day Boys,' from the time at which their violence was commonly perpetrated; the Catholics who associated together for a defence being called 'Defenders.' Collisions between armed bodies of these parties became of frequent occurrence. In 1785, a pitched battle, attended with much bloodshed, was fought in the county

Armagh. The steps taken to repress these disorders were at once insufficient in themselves to prevent open violence, and had the effect of diverting the current into the still more dangerous channel of secret associations. The rude and illiterate mob of Peep-of-day Boys made way for the rich and influential organisation of the Orange Society, which, having its first origin in the same obscure district which had so long been the scene of agrarian violence, by degrees extended its ramifications into every portion of the British empire, and into every grade of society from the hovel to the very steps of the throne. The name of the Orange association is taken from that of the Prince of Orange, William III., and was assumed in honour of that prince, who, in Ireland, has been popularly identified with the establishment of that Protestant ascendancy which it was the object of the Orange association to sustain. The first 'Orange Lodge' was founded in the village of Loughgall, county Armagh, September 21, 1795. The immediate occasion of the crisis was a series of outrages by which Catholics were forcibly ejected from their houses and farms, 12 or 14 houses being sometimes, according to a disinterested witness, wrecked in a single night; terminating, September 1795, in an engagement, called from the place where it occurred, the Battle of the Diamond. The association which began among the ignorant peasantry soon worked its way upwards. The general disaffection towards English rule, which at that time pervaded Ireland, and in which the Catholics, as a natural consequence of their oppressed condition, largely participated, tended much to identify in the mind of Protestants the cause of disloyalty with that of popery; and the rebellion of 1798 inseparably combined the religious with the political antipathies. In November of that year, the Orange Society had already reached the dignity of a grand lodge of Ireland, with a grand master, a grand secretary, and a formal establishment in the metropolis; and in the following years, the organisation extended over the entire province of Ulster, and had its ramifications in all the centres of Protestantism in the other provinces of Ireland. In 1808, it extended to England. A grand lodge was founded at Manchester, from which warrants were issued for the entire kingdom. The seat of the grand lodge was transferred to London in 1821. The subject more than once was brought under the notice of parliament, especially in 1813; and, in consequence, the grand lodge of Ireland was dissolved; but its functions in issuing warrants, &c., were discharged vicariously through the English lodge. The most memorable crisis, however, in the history of the Orange Society was the election of a royal duke (Cumberland) in 1827 as grand master for England; and on the re-establishment of the Irish grand lodge in 1828, as imperial grand master. The Catholic Relief Act of the following year stirred up all the slumbering antipathies of creed and race, and the Orange association was propagated more vigorously than ever. Emissaries were sent out for the purpose of organising lodges, not alone in Wales and Scotland, but also in Canada, in the Mediterranean, and in the other colonies. But the most formidable part of this zealous propagandism was its introduction into the army. As early as 1824, traces of this are discoverable, and again in 1826. No fewer than 32 regiments were proved to have received warrants for holding lodges in Ireland, and the English grand lodge had issued 37 warrants for the same purpose.

The organisation of this strange association was most complete and most extensive. Subject to the central grand lodge, were three classes—county, district, and private lodges—each of which corresponded, and made returns and contributions to

its own immediate superior, by whom they were transmitted to the grand lodge. Each lodge had a master, deputy-master, secretary, committee, and chaplain. The only condition of membership was, that the party should be Protestant, and 18 years of age. The election of members was by ballot, and each lodge also annually elected its own officers and committee. The general government of the association was vested in the grand lodge, which consisted of all the great dignitaries, the grand masters of counties, and the members of another body called the grand committee. This lodge met twice each year, in May and on November 5—the day pregnant with associations calculated to keep alive the Protestant antipathies of the body. All the dignitaries of the society, as well as its various committees and executive bodies, were subject to annual re-election. In 1835, the association numbered 20 grand lodges, 80 district lodges, 1500 private lodges, and from 200,000 to 220,000 members. The worst result of the Orange Association was the constant incentive it supplied to party animosities and deeds of violence. The spirit of fraternity which pervaded its members was a standing obstacle to the administration of the law; and all confidence in the local administration of justice by magistrates was destroyed. An alleged Orange conspiracy to alter the succession to the crown in favour of the Duke of Cumberland, led to a protracted parliamentary inquiry in 1835; and this inquiry, as well as a shocking outrage perpetrated soon afterwards by an armed body of Orangemen, on occasion of a procession in Ireland, so discredited the association, and awakened the public mind to a sense of its folly and wickedness, that its respectability has since that time gradually diminished. For several years the Lord Chancellor laid down a rule, by which no member of the Orange Association was admitted to the commission of the peace; and the association became comparatively without influence, except among the very lowest classes in the north of Ireland. Of the colonial offshoots of the Orange Association, those of Canada have at all times been the most active, carrying with them all the bitterness of the domestic feud with the Roman Catholics. Outrages against Catholic churches and convents were of not unfrequent occurrence until recently; and on occasion of the visit of the Prince of Wales to Canada, an attempt was made to force from his Royal Highness a recognition of the association, which was only defeated by his own firmness, and by the judicious and moderate counsels of his advisers. A few years ago the Orangemen of British America constituted above 1200 lodges, with about 150,000 members. The association has branches in the United States also.

The Orange Association in Ireland, which had begun to fall into general disrepute, received an impulse among the working-classes from a series of sanguinary conflicts with Roman Catholics on occasion of the anniversary celebrations of the society; and even still, the peace of many districts in the north of Ireland is only preserved on such occasions by the presence of an overpowering force of military and constabulary. The repeal of the Processions Act has failed, up to the present time, to put an end to the traditional collisions of the parties.

ORATÓRIO (Ital. *oratorio*, chapel or oratory, the place where these compositions were first performed), a kind of sacred musical composition, either purely dramatic or partaking both of the drama and the epic, in which the text is illustrative of some religious subject, sometimes taken directly from Scripture; and the music consists of recitatives, airs, duets, trios, quartets, choruses, accompanied by an

orchestra, sometimes also by an organ, and introduced by an instrumental overture. The oratorio is not intended for scenic representation.

St Filippo Neri, born in 1515, has been considered the founder of the oratorio. He engaged poets and composers to produce dialogues, on subjects from scriptural and legendary history, in verse, and set to music, which were performed in his chapel or oratory on Sundays and church festivals. The subjects were *Job and his Friends*, *The Prodigal Son*, *The Angel Gabriel with the Virgin*, and *The Mystery of the Incarnation*. Stradella composed various oratorios, of which *San Giovanni Battista*, produced in 1670, is praised by Dr Burney. A number of oratorios, or *azioni sacre*, by Apostolo Zeno and Metastasio, were set to music by Caldara in the beginning of last century. Sebastian Bach's *Passions-Musik* was a species of oratorio, originally performed during the service of the church, the congregation joining in the chorales. Its form arose out of the practice prevalent in the Lutheran Church, of having the gospels for the day repeated on Good Friday, and some other festivals, by different persons in a recitative and dialogue style. By far the greatest master of oratorio was Handel, who perfected that species of composition, and was the first to introduce it into England. At the age of 20, when on a visit to Italy, he produced his oratorio of *La Resurrezione* at Rome. *Esther*, the first oratorio written by him in England, was composed for the chapel of his patron, the Duke of Chandos, in 1720, the words altered from Racine. It was performed privately at Cannons in the same year, but laid aside, and not produced in public till 1732. An oratorio was then so complete a novelty in England, that it was deemed necessary to give the following explanation in advertising it: 'By His Majesty's command, at the King's Theatre in the Haymarket, on Tuesday the 2d May, will be performed the sacred Story of Esther, an oratorio in English, composed by Mr Handel, and to be performed by a great number of voices and instruments.—N.B. There will be no acting on the stage, but the house will be fitted up in a decent manner for the audience.' For many years after the appearance of *Esther*, no more oratorios were produced by Handel, who devoted himself to operas and other secular music; and it was only after the temporary failure of his health, that at the ripe age of 53 he resumed the composition of oratorios. The great oratorios which have made his name immortal were all produced in the decline of life, some of them after he was afflicted with blindness, and they were performed for the most part in the Old Haymarket Theatre. *Deborah* was first performed in 1733; *Athaliah*, in 1734; *Israel in Egypt*, in 1738; *The Messiah*, in 1741; *Samson*, in 1742; *Judas Maccabæus*, in 1746; *Joshua*, in 1747; *Solomon*, in 1749; and *Jephtha*, in 1751. The two crowning works were *Israel in Egypt* and *The Messiah*—the former ranks highest of all compositions of the oratorio class. *The Messiah*—which, in consequence of its text being taken entirely from Scripture, was called by Handel *The Sacred Oratorio*—ranks very near it in point of musical merit, and has attained an even more universal popularity; from the time when it was first brought out, down to the present day, it has been performed for the benefit of nearly every important charitable institution in Britain. *Judas Maccabæus* is perhaps best known from the flowing and martial grace of that unrivalled military march, 'See the Conquering Hero Comes;' and *Saul* is associated in every one's mind with the most solemn of all funeral marches. The orchestra was but imperfectly developed in Handel's time, and his oratorios had therefore originally but

meagre instrumental accompaniments; they have since been generally performed with additional accompaniments written by Mozart. From Handel's time downwards, it was the practice in London to have oratorios performed twice a week during Lent in the various theatres, which were only given up on the institution of the oratorio performances at Exeter Hall. Haydn composed three oratorios—*The Return of Tobias*, *The Seven Last Words*, and *The Creation*. *The Seven Last Words*, a work full of sweetness and of energy, hardly answers to the common conditions of an oratorio; it is rather a series of symphonies, intended to follow as many short sermons on the sentences uttered by our Lord on the cross, the text being a subsequent addition by the composer's brother, Michael Haydn. *The Creation* originated in a visit of Haydn to London in 1791, when he heard for the first time some of the works of Handel, none of which were then known in Germany. Though less grand than the oratorios of Handel, it is full of fresh lovely songs, bright choruses, picturesque recitatives, and exquisite instrumentation. Beethoven's sole oratorio, *The Mount of Olives*, is a pure drama, rather than the mixed composition generally known under the name. Spohr's *Last Judgment*, produced in 1825, contains some grand music, particularly in the choruses. Costa's *Eli* deserves mention among modern oratorios. But since the time of Handel no other writer of oratorios has approached Mendelssohn. The greatest works of that composer are his oratorios of *St Paul* and *Elijah*; the former was first produced at Düsseldorf in 1836, the latter at Birmingham in 1846; and at the time of his death he was engaged in a third oratorio, called *Christus*, which he expected would be his greatest, and of which but a few fragments have been published. Mendelssohn greatly promoted the O. in Britain. Gounod's oratorio, *The Redemption*, first produced at Birmingham in 1882, he regards as his masterpiece. At Exeter Hall in London, and throughout England, oratorios are performed on a large scale, and with a power, a precision, and a perfection unknown elsewhere. The choruses at the provincial festivals are, for the most part, supplied by Birmingham, Manchester, Leeds, and the other large towns. The greatest oratorio performances are now those of the Triennial Festivals at the Sydenham Crystal Palace. At the festival of 1880, the chorus amounted to 2900 voices, and there was an orchestra of 425 performers.

ORATORIIUM (Lat. 'oratory,' called in Greek, *eukterion* or *proseukterion*), as contradistinguished from *ecclesia*, 'a church,' is the name given to an apartment or building designed for worship of a private or domestic character. From the earliest times, the use of oratoria is traceable in the history of the church; and before the regular organisation of parishes, they had probably a considerable place in the common, although not in the public worship. At a later period, oratoria became a common appendage of the castles and residences of the nobility, and were of two kinds; the first, simply for private or family prayer and other devotion; the second, for the celebration of mass. The latter fell properly under the jurisdiction of the bishop or the parochial clergy, and many jealousies and disputes grew out of their establishment or direction. The Council of Trent (Sess. xxii., *De Reformatione*) placed them under very stringent regulations, which have been enforced and developed by later popes, especially by Benedict XIV.

O'RATORY, CONGREGATION OF THE. The origin of this learned Congregation, and its early history, have been detailed under the head of ST PHILIP NERI (q. v.). It is remarkable, however, that this

extraordinary man, unlike most other founders of religious bodies in the Roman Catholic Church, had never committed to writing any definite body of rules for the government and direction of the brethren. Even his scattered papers, from which his plans and intentions might have been collected, had been burned by his orders a short time before his death. Soon after that event, the Fathers, at the instance of Baronius, compiled from the existing practices and from memory a rule for the Congregation, framed so as to embody the spirit of St Philip. This rule was approved of by Paul V. on February 21, 1612. The Fathers of the Congregation are a body of priests living in community, but without vows, and under a constitution of a highly democratical character. They are at liberty to withdraw at any time, and to resume possession of the property which they had brought with them at entrance; and even during their association, each member manages his own financial concerns, only contributing a fixed sum to the common expenses of the community. There is no superior-general, as in other orders. Each house is distinct and independent. In each, the superior is elected only for three years, and his position does not give him any personal pre-eminence whatever. The members take their places according to seniority, not according to official rank, and the superior is compelled to take his turn in all the duties, even down to the semi-menial office of serving in the refectory. The main occupations of the Fathers, beyond those of attending to the public service of the church, and the duties of the pulpit and the confessional, lie in the cultivation of theological and other sacred studies, of which 'conferences' for the discussion, in common, of theological questions, form a principal feature. The Congregation has produced many men of great eminence in sacred science, among whom have been already named the great church historian, Cardinal Baronius, and his continuators. To these may be added the celebrated explorers of the Roman catacombs, Bosio, Severani, and Aringhi; and the no less eminent patristical scholar, Gallandi. The houses of the Oratory in Italy before the Revolution were numerous, and in high repute. Few towns of any importance were without a house of the Oratory. The Congregation was early established in France by the celebrated Pierre (afterwards Cardinal) de Berulle, in common with two Italian Fathers, and from France it extended to the Low Countries. One important difference, however, is noticeable between the French Oratory and the Roman original. In the former, all the houses of the country are subject to a single superior-general. In France, also, the Oratorians took charge of seminaries and of theological teaching. The French Oratory, as well as the Italian, reckons many illustrious members; but the fame and utility of the French Congregation were much marred by the unhappy controversy about Jansenism. In the year 1847, this Congregation was introduced into England by Dr John Henry Newman (q. v.). Soon after his secession from Anglicanism, he established a house, the members of which were for the most part ex-Anglicans like himself, near, and finally at Birmingham; and soon afterwards, a second at London, which has since been transferred to Brompton.

ORBIS PICTUS (the *Pictured World*), the title of the first picture-book or illustrated manual of instruction for the young, by the celebrated educationist, Comenius, published at Nürnberg in 1657. It was long a great favourite with the youth of Germany, and continued to be reprinted, in various modified forms, down to recent times. Comenius, with the instinct of a great teacher, felt

that to give words without things to the pupil was not simply to retard his progress, but to lay the foundation of vague and inaccurate conceptions. Hence his introduction of the pictures of things into the work above named, which, among other things, was intended for those beginning the study of Latin, the connecting of the word with the picture tending to give the pupil a firmer hold or a quicker perception of both word and thing. The great and distinguishing merit of Comenius's book is, that it brought distinctly into notice the necessity of giving children in the earliest stages of their education, not simply a word, but the form of the thing of which the word was the symbol. A further advance on this idea was made by Pestalozzi, who aimed at presenting to the eye of the child the thing itself, whenever it was practicable to do so; and he regarded this as essential to the right education of the human faculties in their infancy. From this, again, flowed the excellent custom of giving Object Lessons in Infant Schools.

ORBIT, in Astronomy, is the path described in space by a heavenly body in its revolution round its primary.* The path so described is of an elliptic form, and would be accurately an ellipse, were it not for the disturbing influence of the other heavenly bodies. See PERTURBATIONS. The complete determination of a planet's orbit is of the last importance to astronomers, as it enables them to predict the planet's place in the heavens at any period, and thus determine the exact date of eclipses of the sun and moon, of transits and occultations of the planets, and of the appearances and disappearances of comets. For the determination of a planet's orbit, it is necessary to know three things: 1. The situation of the *plane* of the orbit in space; 2. The position of the orbit in this plane; and 3. The situation at a given epoch, and rate of motion, of the planet in its orbit. Since the plane of the ecliptic is for convenience taken as the reference plane, the position of the plane of a planet's orbit is known when its inclination to the plane of the ecliptic (1), and the line of intersection of the two planes (2), are known. Since the sun, which is the focus of the planetary orbits, lies in this line of intersection, the orbit cannot lie wholly above or below the plane of the ecliptic, but must cut it in two points, called *Nodes* (q. v.), and the position of the line of intersection, or line of nodes, is generally given in terms of the longitude (or angular distance) of the ascending node, reckoning from the equinox. The situation of a planet's orbit in its plane is determined when we know its form (3), size (4), and the position of its major axis or line of apsides (5). The size and form of the orbit depend upon the length of its major and minor axes, but astronomers prefer to employ the major axis and eccentricity (see ELLIPSE); and the position of the major axis is known by determining the heliocentric longitude of its *perihelion* (i. e., the extremity of it which is nearest the sun). To complete our knowledge of a planet's motion, all we now require are the epoch of its appearance at some determinate point of its orbit, say, at the perihelion (6), and the velocity of its motion in its orbit (7), for when this last is known, the law of areas, as given in Kepler's second law, enables us to determine the position of the planet in its orbit at any future period. These seven facts, the possession of which gives us a complete clue to a planet's motion, are called the seven 'elements of a planet's orbit.' What has been here stated concerning the planetary orbits, is equally

* The sun is the primary of the planets and comets, and each planet is the primary of its satellites (secondary planets).

true of the orbits of the comets and satellites, though, in the case of the latter, the effect of disturbing forces is so great as to produce a considerable change of the elements in one revolution.

O'ROHARD (Goth. *aurtigard*, Middle High Ger. *wurzgarte*, Ang.-Sax. *vyrtgeard*, *ortgeard*, a yard or garden for yards or vegetables), a piece of ground specially devoted to the growth of fruit-trees, and in which these are planted as near to each other as their profitable cultivation will admit of, no space being left for culinary vegetables, as in the fruit-garden. The introduction of such crops to any considerable extent is injurious to the trees of an orchard, by exhausting the soil, and the vegetables produced are not good. In some orchards, the soil is regularly digged, and manure pretty freely supplied, the trees being *dwarf standards*, trained to a low and bushy form, in rows about twelve feet apart, with rows of gooseberries, currants, or raspberries between them. Such orchards are often very productive, and are not liable to suffer much from winds, whilst the trees also protect each other from frosts in spring. Other orchards are formed in old pastures, the turf being replaced when the trees are planted, or, if they are formed on land that has been under the plough, it is sown down with grass. In these, also, manure is occasionally given. In many cases, the grass of orchards is employed for pasturing cattle or sheep, the trees being standards or half-standards, with stems so tall that their branches are beyond the reach of the animals, and in this way the grass produced by the soil is returned to it in the form of manure. In forming orchards of this kind, it is not unusual to plant the *stocks*, upon which the proper grafts or buds are afterwards inserted. Great orchards of this kind exist in Devonshire, Herefordshire, and some other southern counties of England, devoted to the growth of apples for the production of cider, and to a smaller extent, of pears for the production of perry. Orchards are not so common in Scotland as in England, where they are not only frequent appendages of the manor-house, but even of the farm-house. Apples, pears, plums, and cherries, not of the finest kinds, are the fruits chiefly produced in British orchards, although some in England also yield walnuts, chestnuts, medlars, mulberries, quinces, &c., and there are even a few small fig-orchards in the most southern parts. Fig and peach orchards are very common in the more southern parts of Europe; and oranges, lemons, &c., on the shores of the Mediterranean.

An orchard requires a dry soil, which ought also to be free and open, not a stubborn clay. A gentle slope, exposing it to the sun, is preferable to perfectly level ground. Protection from prevalent winds, especially in Britain from the south-west winds which often blow strongly in autumn, is very necessary; but it is not less important that there should be a free circulation of air, in default of which the trees become covered with lichens and mosses, and cease to be productive. An orchard is often surrounded by a hawthorn-hedge, but a small orchard must not have a very high hedge. Forest trees are often planted as a screen, but must not be too near. Where walnut and chestnut trees will ripen their fruit, they are often planted, on the side most exposed to winds, for shelter.

In laying out the ground for an orchard, it is not unusual to form it into ridges, on the crown of which the trees are planted. But, however this may be, the trees are planted in rows running north and south, so that the rays of the sun may penetrate among them somewhat equally. In planting the trees, their roots are spread out as much as possible, as it is found desirable to encourage

them to extend near the surface, rather than to penetrate deep into the ground, particularly where no digging or cropping is intended. The remarks on soil and manures in the article **FRUIT-GARDEN** are applicable also to orchards.

The districts of Scotland most celebrated for their orchards are a portion of Clydesdale (Lanarkshire) and the Carse of Gowrie (Perthshire), in both of which the apple-orchards are of very considerable economical importance.

ORCHARD-HOUSE, a structure adapted to the cultivation of fruits, of finer kinds than can be produced in the open air, or in greater perfection, without the aid of artificial heat. It is the invention of Mr Rivers of London, and is a 'glass-roofed shed,' the front of which is lower than the back, so that the roof slopes towards the sun. The merit of the invention, however, consists not so much in the structure itself, or in the protecting of fruit-trees and admitting of the sun's rays by glass, as in the mode of their treatment, by which a limited space can be made to produce a prodigious quantity of fine fruit. The trees are planted in pots, are never allowed to attain a considerable size, and are so trained and pruned as to have the greatest possible amount of fruitful wood within the smallest possible compass. The pots have a large hole in the bottom, through which the roots may pass; and are placed upon a border carefully prepared for them, of loose and open materials, such as cinders, lime-rubbish, and broken bricks, enriched by manure. After the fruit is gathered, the roots are cut through at the bottom of the pot, and the trees are set aside to rest for the winter; and this treatment is repeated from year to year. The orchard-house is generally a very low structure, so that the foliage and fruit are very near the glass; its back being only 7 feet high, and its front only 2½ feet, for a width of 12 feet. A path is excavated as a trench of 2 feet deep, and 2½ feet wide, through the middle of it. For details as to glazing, ventilation, &c., we refer to Mr Rivers's pamphlet, *The Orchard-house*, and to Chambers's *Information for the People*, i. pp. 591-2 (new ed.). Plants for orchard-houses may now be purchased in nurseries. In the pamphlet of Mr Rivers, instructions will be found as to the training and treatment of different kinds of trees.

O'ROHESTRA (Gr. *orchēstra*, from *orchēomai*, I dance), in the Greek theatres, the place allotted to the chorus of dancers; in modern theatres, the part of the building assigned to the instrumentalists; and in the modern concert-room, the place occupied by the instrumental and vocal performers. The word orchestra is also used to denote the musicians collectively.

A complete orchestra consists of stringed and wind instruments, and instruments of percussion. The employment of stringed and wind instruments together was long deemed a barbarism. Glück was among the first composers who shewed that they could be effectively combined, and his ideas were more fully developed by succeeding composers. The perfecting of the old instruments, and the introduction of new ones, formerly confined to military bands, have added immensely to the power and resources of the modern orchestra, whose capacities, however, have sometimes been misused.

The proper strength of an orchestra must depend on considerations connected with the locality. The stringed instruments should in all cases greatly outnumber the wind instruments; and those latter, the instruments of percussion. The stringed instruments in general use are the violin, viola, violoncello, and double-bass, and their force often amounts to as many as fifty, while even in a large orchestra

there are seldom more flutes, hautboys, or bassoons than two of each. The horn, trumpet, and ophicleide or serpent, the other wind instruments admitted into the orchestra, are used as sparingly; and of instruments of percussion, a pair of kettle-drums is often considered sufficient, though cymbals and triangles are occasionally added. In a small orchestra, trumpets, trombones, the serpent, and the kettle-drum should be avoided as being too noisy. By far the greatest part of the work falls to the share of the stringed instruments, the parts for which form a complete quartett for first violin, second violin, viola, and violoncello, which should be perfect within itself, independently of the parts for the wind instruments. The object of the double-bass is to enforce the violoncello part. This full quartett is occasionally interrupted by harmony in two or three parts, or passages in unisons or octaves. The success of the combination of wind and stringed instruments depends on the skill and judgment of the composer. The bassoon, horn, or flute may double any given part of the stringed instrument quartett, so as to produce an effect of reinforcement, or it may have its own distinctive melody. An occasional variety is produced by the entire cessation of stringed instruments for a short period, letting the wind instruments be heard alone.

The orchestra of a concert-room should be so arranged that the front is about five feet above the level of the floor, and it should rise gradually in steps towards the end wall, whose angles ought to be rounded off so as to enable the whole body of sound to be reflected. Reverberation is essential to the proper effect of music. From the exigencies of dramatic representation, a theatrical orchestra must necessarily be much inferior to a concert orchestra; the instrumentalists, brought together in the lowest part of a theatre on a horizontal plane between the spectators and the stage, are deprived of most of the advantages arising from a proper arrangement.

ORCHIDÆÆ, or ORCHIDACEÆ, often popularly called ORCHIDS, a natural order of endogenous plants, remarkable for the structure of their flowers, which are also of great beauty and exquisite fragrance. The perianth sometimes exhibits much variety of forms, even in the same species; but is always irregular, its segments differing much from each other. There are usually six segments, arranged in two rows (*calyx* and *corolla*); although some of the most extraordinary forms of orchideous flowers are produced by the combination of certain segments into one piece. Spurs and other appendages of some of the segments are also common. The inner segments are often beautifully coloured. The inferior segment of the corolla is called the lip (*labellum*), and is often lobed, spurred, or furnished with curious appendages of different kinds. The stamens are united with the style into a single central column; the distinctive character of the Linnæan class *Gynandria*, of which the *O.* form the chief part. There is usually only one anther, with a tubercle on each side of it, the tubercles being abortive anthers; but sometimes the two lateral anthers are perfect, and the central one is abortive; and very rarely all the three anthers are perfect. The anthers are usually two-celled; the grains of pollen cohering in two or more masses. The ovary is inferior, one-celled; the stigma usually a mere hollow in front of the column. The fruit is usually a capsule, opening with six valves, three of which have placentæ; the seeds numerous and very small. In a few cases, the fruit is fleshy. The *O.* are generally herbaceous perennials; but some of those found in warm

climates are shrubs, and some of these, as *Vanilla*, are climbers. The root is usually composed of simple, cylindrical fibres, which are often accompanied with one or two fleshy tubercles, a tubercle dying and a new one being produced annually.

Ophris morio :
a, parts of the flowers.

The leaves are always simple, alternate, often sheathing at the base, often leathery, sometimes arising, in tropical species, not directly from the stem, but from fleshy bulb-like excrescences of it. —The species of *O.* are very numerous, about 3000 having been described. They are found in all parts of the world, except the coldest and the most arid regions; but are most numerous in the humid forests of the torrid zone, and particularly in America. Many of them are epiphytes, adorning the boughs of trees with splendid flowers. This is chiefly the case with tropical species, those of colder climates mostly growing on the ground. Only about thirty-eight species are reckoned in the British flora.—*SALP* (q. v.), a delicate and nutritious article of food, is obtained from the root-tubercles of a number of species. The only other product of the order, which is of any commercial importance, is *Vanilla* (q. v.). The fragrant *Faam* (q. v.) leaves are the leaves of an orchid. Several species are known to possess tonic, stimulant, and antispasmodic properties, but none are of much importance in medicine.

Orchids have of late been much cultivated on account of their flowers, and many tropical species are amongst our most esteemed hothouse plants; houses being sometimes specially devoted to them. Many of the epiphytal kinds may be planted in pots filled with loose fibrous peat, the roots of others are placed in baskets, or are fastened to blocks of wood, with a little moss or some such thing around them, to keep them from becoming too dry, and are thus placed on the shelves, or suspended from the roof of the house. Careful attention to temperature is necessary, and also to ventilation; and although much heat and moisture are requisite, the atmosphere must not be constantly very hot and humid, but seasons of rest must be given to the plants, which in their native climates have generally a wet and a dry season, the latter being to them in many respects what the winter is to plants of temperate regions.

Lindley has particularly signalised himself in the study of this interesting order of plants.

ORCHIL AND ORCHELLA WEED. See **ARCHIL**.

ORCHIS is a genus of *Orchideæ*, to which, as now restricted, eleven of the British species are referred. Some of them are among the most common of British *Orchideæ*, adorning meadows and pastures with their flowers in summer. The roots

Orchis mascula :
a, the lip of the perianth.

of some of the species yield salep. The lip of the flower in this genus has a spur. The flowers of the Early Purple O. (*O. mascula*), one of the most common species, are sometimes fragrant; but those of the Lizard O. (*O. hircina*), found in chalky districts in the south of England, are remarkable for their disagreeable goat-like or lizard-like smell.

ORCHOMENOS, a famous and very ancient city of Boeotia, the capital of the once independent kingdom of the Minyæ, and hence called Minyean O., to distinguish it from another O. in Arcadia. It was situated northward from the Lake Copais, on the left bank of the Cephissus, and extended from the marshy edges of the lake up the face of a steep rocky hill, on which stood the Acropolis. In the earliest times, its dominions extended to the sea. Homer compares its treasures to those of Egyptian Thebes, and tells us that it sent 30 ships to the Trojan war. Some time after this event, it became a member of the Boeotian confederacy. During the Persian war, like the other towns of Boeotia, it abandoned the national cause. Its government was thoroughly aristocratic, and after the Peloponnesian war, when Thebes became a democracy, O. took part with Sparta, and shared in its first triumph over Thebes; but the victory of Epaminondas at Leuctra (371 B.C.) placed O. at the mercy of the Thebans, who soon after destroyed it by fire, and sold its inhabitants as slaves. It was again rebuilt during the Phocian war, but a second time destroyed in the reign of Philip of Macedon, who, however, once more rebuilt it; but it never again became prominent in history. O. was famous for its great musical festival in honour of the Graces, when poets and musicians assembled from all quarters to compete for prizes. The ruins of O. are still to be seen near the modern village of Skripú.—See K. O.

Müller's *Orchomenos und die Minyer*, Leake's *Northern Greece*, and Mure's *Tour in Greece*.

ORCIN AND ORCEIN are colouring matters obtained from lichens. Orcin ($C_{14}H_8O_4 + 2Ag$) may be obtained by boiling certain species of *Rocella* or *Lecanora* with lime for some hours, removing the lime, by a current of carbonic acid, evaporating and extracting with boiling alcohol, from which the orcin separates in red crystals. With chloride of lime, it gives a purple red colour, which quickly changes to a deep yellow. Orcin is the true colour-producing substance or chromogen of these lichens. In the presence of ammonia, it absorbs oxygen, and is converted into *orcein* ($C_{14}H_7NO_5$), a nitrogenous compound of strong tinctorial power. When isolated, orcein forms a red flocculent powder, which is freely soluble in alcohol, forming a scarlet fluid. Potash and ammonia dissolve it readily, forming a splendid purple colour, which is the basis of the ordinary archil of commerce. With metallic salts, its alkaline solutions yield beautiful purple lakes.

ORDEAL (Anglo-Saxon, *ordaæl*; from *or*, primitive, and *daal*, judgment; Ger. *Urtheil*, judgment), a practice which has prevailed largely among various widely-separated nations, of referring disputed questions, particularly such as relate to the guilt or innocence of an individual, to the judgment of God, determined either by lot, or by the success of certain experiments. Of its existence among the ancient Jews, we have an instance in Numbers v., where a Hebrew woman, accused of adultery, is required to drink the waters of jealousy as a test of innocence; a similar ordeal for incontinence is in use among the natives of the Gold Coast of Africa. Compurgation of accused persons by fire, as existing among the Greeks, is referred to in Sophocles's *Antigone*. Among the Hindus, the ordeal has been in use to be practised in nine different ways—by the *balance*, by *fire*, by *water*, by *poison*, by the *cosha* or drinking water, in which images of the sun and other deities had been washed, by *chewing-rice*, by *hot oil*, by *red-hot iron*, and by drawing two images out of a jar into which they have been thrown. (*Asiatic Researches*, vol. i. p. 389.)

The ordeal seems to be prevalent throughout Africa. 'When a man,' says Dr Livingstone, 'suspects that any of his wives have bewitched him, he sends for the witch-doctor, and all the wives go forth into the field, and remain fasting till that person has made an infusion of the plant (called "goho"). They all drink it, each one holding up her hand to heaven in attestation of her innocence. Those who vomit it are considered innocent, while those whom it purges are pronounced guilty, and put to death by burning. The innocent return to their homes, and slaughter a cock as a thank-offering to their guardian spirits. The practice of ordeal is common among all the negro nations north of the Zambesi.' The women themselves eagerly desire the test on the slightest provocation; each is conscious of her own innocence, and has the fullest faith in the *muavi* (the ordeal) clearing all but the guilty. There are varieties of procedure among the different tribes. The Barotse pour the medicine down the throat of a cock or dog, and judge of the innocence or guilt of the person accused by the vomiting or purging of the animal.

Throughout Europe in the dark ages the ordeal existed under the sanction of law, and of the clergy. The most prevalent kinds of ordeal were those of *fire*, *water*, and the *wager of battle*. *Fire ordeal* was only allowed to persons of high rank. The accused had to carry a piece of red-hot iron for some distance in his hand, or to walk nine feet barefoot and blindfolded over

red-hot ploughshares. The hand or foot was bound up and inspected three days afterwards: if the accused had escaped unhurt, he was pronounced innocent; if otherwise, guilty. Under such a judicial system, there were probably few acquittals; but it is believed that in the severer kinds of ordeal, precautions were sometimes taken by the clergy to protect those whom they wished to clear from suspicion. Queen Emma, mother of Edward the Confessor, when suspected of a criminal intrigue with Alwyn, Bishop of Winchester, is said to have triumphantly vindicated her character by walking unhurt over red-hot ploughshares. *Water ordeal* was the usual mode of trial allowed to bondsmen and rustics, and was of two kinds—the ordeal of *boiling water*, and of *cold water*. The ordeal of *boiling water*, according to the laws of Athelstane, consisted in taking a stone out of boiling water, where the hand had to be inserted as deep as the wrist; what was called the triple ordeal, deepened the water to the elbow. The person allowed the ordeal of *cold water* (the usual mode of trial for witchcraft), was flung into a river or pond; if he floated without any appearance of swimming, he was judged guilty—while if he sank, he was acquitted.

The *wager of battle* was a natural accompaniment of a state of society which allowed men to take the law into their own hands. The challenger faced the west, the challenged person the east; the defeated party, if he craved his life, was allowed to live as a 'recreant;' that is, on retracting the perjury which he had sworn to. See BATTEL, TRIAL BY.

Other kinds of ordeal were practised in particular circumstances in different parts of Europe. In the ordeal of the *bier*, a supposed murderer was required to touch the body of the murdered person, and pronounced guilty if the blood flowed from his wounds. The ordeal of the *Eucharist* was in use among the clergy: the accused party took the sacrament in attestation of innocence, it being believed that, if guilty, he would be immediately visited with divine punishment for the sacrilege. A somewhat similar ordeal was that of the *corned*, or consecrated bread and cheese: if the accused swallowed it freely, he was pronounced innocent; if it stuck in his throat, he was presumed to be guilty. Godwin, Earl of Kent, in the reign of Edward the Confessor, when accused of the murder of the king's brother, is said to have appealed to the ordeal of the corned, and been choked by it. An early form of ordeal, abolished by Louis le Debonnaire in 816, was that of the *cross*: the accuser and accused stood upright before a cross, and he who first fell, or shifted his position, was pronounced guilty. It was done away with, as being irreverent towards the mystery of the cross. Besides these, there was the ordeal by *lot*, dependent on the throw of a pair of dice, one marked with a cross, the other plain.

Trial by ordeal at first carried with it the sanction of the priests, as well as of the civil power, though the clergy in the course of time came to discountenance it. In England it seems to have been continued till the middle of the thirteenth century. On the continent it was, generally speaking, abolished rather earlier, although as late as 1498 we find the truth of Savonarola's doctrine put to the test, by a challenge between one of his disciples and a Franciscan friar, to walk through a burning pile. In Scotland, in 1180, we find David I. enacting, in one of the assemblies of the frank tenantry of the kingdom, which were the germ of parliaments, that no one was to hold an ordinary court of justice, or a court of ordeal, whether of battle, iron, or water, except in presence of the

sheriff or one of his sergeants; though if that official failed to attend after being duly summoned, the court might be held in his absence. The first step towards the abolition of this form of trial in Saxon and Celtic countries, seems to have been the substitution of compurgation by witnesses for compurgation by ordeal. The near relatives of an accused party were expected to come forward to swear to his innocence. The number of compurgators varied, according to the importance of the case; and judgment went against the party whose kin refused to come forward, or who failed to obtain the necessary number of compurgators. To repel an accusation, it was often held necessary to have double the number of compurgators who supported it, till at length the most numerous body of compurgators carried the day.

ORDER. In Classic Architecture, the Order or ordonnance comprises the column with its base and capital and the entablature. There are five orders: (1) Tuscan, (2) Doric, (3) Ionic, (4) Corinthian, (5) Composite. The first and fifth are Roman orders, and are simply modifications of the others. The remaining three are the Greek orders. See COLUMN, GREEK ARCHITECTURE, ROMAN ARCHITECTURE.

ORDER, in Natural History, a group constituted for the purpose of classification, inferior to *class* and *sub-class*, but superior to *family*, *tribe*, *genus*, &c. The term **NATURAL ORDER** is used in botany to designate an order belonging to the natural system of classification, in contradistinction to one of an artificial system devised for mere convenience of the student, and signifies that the limits of the order agree with the truth of nature, and that it thus exhibits affinities really existing. In all branches of natural history, classification now proceeds on this principle.

ORDER. This word is applied to an aggregate of conventual communities comprehended under one rule, or to the societies, half military half religious, out of which the institution of knighthood sprang. Religious orders are generally classified as monastic, military, and mendicant.

The earliest comprehension of monastic societies under one rule was effected by St Basil, Archbishop of Cæsarea, who united the hermits and cenobites in his diocese, and prescribed for them a uniform constitution, recommending at the same time a vow of celibacy. The Basilian rule subsists to the present day in the Eastern Church. Next in order of time was the Benedictine order, founded by St Benedict of Nursia, who considered a mild discipline preferable to excessive austerities. The offshoots from the Benedictine order include some of the most important orders in ecclesiastical history, among others the Carthusians, Cistercians, and Præmonstrants. The order of Augustinians professed to draw their rule from the writings of St Augustine; they were the first order who were not entirely composed of laymen, but of ordained priests, or persons destined to the clerical profession.

The military orders, of which the members united the military with the religious profession, arose from the necessity under which the monks lay of defending the possessions which they had accumulated, and the supposed duty of recovering Palestine from the Saracens, and retaining possession of it. The most famous orders of this kind were the Hospitallers or Knights of St John of Jerusalem, the Knights Templars, and the Teutonic order. Many other military orders existed, and not a few continue to exist, particularly in Spain and Portugal. The phraseology of the old military orders is preserved in the orders of knighthood of modern

times, into which individuals are admitted in reward for merit of different kinds, military and civil.

The three mendicant orders of Franciscans, Dominicans, and Carmelites were instituted in the 13th century. Their principal purpose was to put down the opposition to the church, which had begun to shew itself, and also to reform the church by example and precept. At a later period the order of the Jesuits was founded, with the object of increasing the power of the church, and putting down heresy.—Notices of the more important orders, monastic, military, and mendicant, will be found under separate articles. See also KNIGHTS and MONACHISM.

ORDERICUS, VITALIS, a medieval historian, born at Aetham, near Shrewsbury, in 1075, was taken to France at the age of five, and educated for the monastic life in the abbey of Ouche, at Lisieux. He became a priest in 1107, and died, it is thought, about 1143. O. is the author of a so-called Church History (*Historia Ecclesiastica*), in 13 vols. It is a chronicle of events from the birth of Christ down to his own time. Books 3—6 give an account of the Norman wars in England, France, and Apulia down to the death of William the Conqueror. The last half of the book is the most valuable, being a record of the history of the author's own times. The first edition of the *Historia Ecclesiastica* was published by Duchesne, in his *Hist. Norm. Scrip.* (1619). It has also been printed by the French Historical Society (1840), and was translated into English by Forester (4 vols.—Bohn's *Antiquarian Library*).

O'ORDERLIES are soldiers or sergeants appointed to wait upon general and other commanding officers, to communicate their orders, and to carry messages. The *Orderly Officer*, or officer of the day, is the officer of a corps or regiment, whose turn it is to superintend its interior economy, as cleanliness, the goodness of the food, &c. *Orderly Non-commissioned Officers* are the sergeants in each company who are 'orderly,' or on duty for the week. On the drum beating for orders, they proceed to the Orderly Room, take down the general or regimental orders affecting their respective companies, shew them to the company officers, and warn the necessary men for any duties specified in those orders. An *Orderly Book* is provided by the captain of each troop or company in a regiment for the insertion of general or regimental orders from time to time issued.

ORDERS, ARMY, are general, divisional, brigade, or regimental. General orders are issued by the commander-in-chief of an army, and affect the whole of his force. The others emanate from generals of division or brigade, or from officers commanding regiments, and severally affect their respective commands.

ORDERS IN COUNCIL, orders by the sovereign with the advice of the privy council. The privy council of Great Britain has no power to legislate, except so far as authorised to do so by parliament; but in periods of emergency, it has nevertheless occasionally issued and enforced orders of a legislative kind; those who were concerned in passing, promulgating, or enforcing the orders, trusting to parliamentary protection, and taking on themselves the personal responsibility of the proceeding. In such cases, an act of indemnity afterwards passed has relieved from liability those who advised the order or acted under it, and given compensation to all who suffered by its enforcement. This course was adopted in 1766 with regard to an embargo on the exportation of corn, issued in consequence of a deficient harvest and prospect of famine. An important constitutional question was raised by the famous Orders

in Council issued by Great Britain in 1807 and 1809, in reprisal for Napoleon's Berlin and Milan decrees. The Berlin decree, issued on the 21st of November 1806, declared the whole of the British islands to be in a state of blockade, and all vessels trading to them to be liable to capture by French ships. It also shut out all British vessels and produce both from France and from all the other countries which gave obedience to the French. A subsequent decree, issued soon afterwards, obliged all neutral vessels to carry letters or certificates of origin—that is, attestations by the French consuls of the ports from which they had sailed, that no part of the cargo was British. In retaliation for the Berlin decree, the British government issued, on the 7th January 1807, an Order in Council, subjecting to seizure all neutral vessels trading from one hostile port in Europe to another with property belonging to an enemy. This order was at first extensively evaded, while the French made vigorous efforts to enforce the Berlin decree; the result was, that new Orders were issued by the British government on the 11th and 21st of November 1807, declaring France and all states subject to the French to be in a state of blockade, and all vessels liable to seizure which were found to have certificates of origin on board, or which should attempt to trade with any of the ports of the world thus blockaded. Neutral vessels intended for France, or any other hostile country, were ordered, in all cases, to touch first at some British port, and to pay custom-house dues there, after which they were in certain cases to be allowed to depart for their destination; and vessels clearing from a hostile country were similarly to touch at a British port before proceeding on their voyage. On the 27th of December 1807, Napoleon's Milan decree was issued, which declared the whole British dominions to be in a state of blockade, and all countries were prohibited from trading with each other in any articles of British produce or manufacture. The Americans, and those of the public of Great Britain who were interested in the export trade, exclaimed loudly against the edicts of both powers, and the legality as well as the expediency of the Orders in Council were called in question in parliament. The result was, that an inquiry was instituted into the effect of the orders, from which no direct result followed. But, in the meantime, on the 26th April 1808, a new Order in Council was issued, limiting the blockade to France, Holland, a part of Germany, and the north of Italy, and the order which condemned vessels which had certificates of origin on board was rescinded. Subsequent orders introduced a system of furnishing licences to vessels to proceed to hostile ports after having first touched and paid custom-house dues at a British port; no fewer than 16,000 of these licences are said to have been granted. The legality of these Orders has been called in question, on the ground that they were more of a legislative than an executive character, in so far as a fictitious blockade, where there is no blockading force present, is contrary to the law of nations; it has been defended on the ground that they were issued in execution of the royal prerogative of declaring and conducting war. They are generally believed to have added to the general distress, and the check on the progress of manufactures produced by Napoleon's decrees; but, on the other hand, it has been maintained that they were essential to the effective prosecution of the war.

There are various matters connected with trade and the revenue as to which Orders in Council have been authorised by statute; parliament, in

fact, delegating its legislative authority to the Queen in Council. For example, the International Copyright Act, 7 and 8 Vict. c. 12, contains a provision for empowering the crown, by Order in Council, to extend the privileges of British copyright to works first published in any state which gives a like privilege to the productions of this country.

ORDERS, HOLY, an institution regarded in the Greek and Roman churches as a sacrament, by which ministers are specially set apart for the service of religion, and are regarded as receiving a certain religious consecration, or, at least, designation for their office. While some of the reformed churches altogether deny the distinction of ranks in the ministry, none of them admits more than three ranks, of bishop, priest, and deacon. But in the Roman and Greek churches, a further classification exists. In the Roman Church, a distinction is made between the major (or holy) orders and the minor orders. Of the major orders, three have been described in general terms, under the head **HIERARCHY** (q. v.), viz., the classes of bishops, priests, and deacons. A fourth rank of sub-deacons is generally regarded as one of the major orders, but its functions closely resemble in their nature and their degree those of the deacon. The minor orders in the Roman Church are four in number—those of door-keeper, reader, exorcist, and acolyte. To none of these orders is any vow of celibacy annexed. Some of their functions had their origin in the peculiar religious condition of the early church. The duties of door-keeper arose chiefly out of the discipline in regard to the penitents and catechumens; but although these functions find no room in the modern discipline of the Roman Church, the door-keeper of the modern church is held to succeed to other functions of his ancient prototype in relation to the catechetical instruction of children and of the poor and ignorant. Preparatory to the receiving of these orders, candidates are initiated in what is called the *Tonsure*, which consists in the cutting off of the hair, as a symbol of separation from the world and its vanities—a rite which appears also as one of the ceremonies of the religious profession. Tonsure, however, is not reckoned as an order; it is but a distinguishing characteristic of a class. In the Roman Church, the sacrament of orders is held to produce an indelible character, and therefore to be incapable of being forfeited and of being validly repeated. This, however, applies only to the holy orders. The Greek Church has the distinction of major and minor orders, in common with the Roman. But the Greeks commonly exclude sub-deaconship from the major orders, and all the functions of the four minor orders of the Roman Church are united by the Greeks in one single order, that of reader (*anagnostes*).

In the Anglican and other Reformed Episcopal Churches, the three higher orders of bishop, priest, and deacon are alone retained. An Anglican clergyman may be deprived of his benefice, or suspended by his bishop for various ecclesiastical offences; and the right of the Court of Arches to pronounce sentence of deprivation has also been recognised. But in the usual case of deprivation, the clergyman does not forfeit his status of priest or deacon, which can only be lost by deposition or *degradation*. Statute 23, Hen. VIII., c. 1. s. 6, reserves to the ordinary the power of degrading clerks convicted of treason, petit treason, murder, and certain other felonies before judgment. A bishop may be deprived of his see by his metropolitan, with or without the co-operation of a synod of the bishops of the province, but it has been questioned whether he can be lawfully

deprived of his orders as bishop. A clergyman of the Church of England and Ireland cannot become a member of the House of Commons. In the Presbyterian and other non-episcopal churches, the ceremony of ordination is not held to impart any indelible character. A minister found guilty of heresy or immorality, is deprived of his office by *deposition*, by which his clerical status is forfeited. His removal from his charge, however, in any other way, does not affect his office as a minister; and a minister removed from one charge to another, or, after a time, inducted into a new charge, is not re-ordained. A minister having no charge or flock, may yet dispense the sacraments, if duly called upon. A minister deposed ceases altogether to be a minister, and is no more capable of any of the functions of the office, than if he had never been ordained.

The ceremony of *imposition of hands* is used in almost all Protestant churches in the ordination of ministers, the ordaining bishop or presbyters placing the right hand on the head of the person ordained; and is always accompanied with prayer. It is deemed a proper and Scriptural form (1 Tim. iv. 14), but not essential.

In the Church of Scotland and other Presbyterian churches, when an already ordained minister is inducted into a new charge, no imposition of hands takes place. In the Scottish and American Presbyterian churches, candidates for the ministry are *licensed to preach the gospel* before being called to any particular charge, and are then styled *licentiates* or *probationers*. They are licensed, according to an old phrase, 'for trial of their gifts,' but are not entitled to dispense the sacraments.

There is nothing to prevent a minister of the Church of Scotland, or any Presbyterian or Independent church, from being a member of the British House of Commons.

O'RDINAL, the service used in Episcopal churches for the ordination of ministers. The English ordinal was drawn up by a commission appointed in the third year of Edward VI. (1550), and added to the *Book of Common Prayer*. It was slightly modified in the reign of Elizabeth, and was again revised by the Convocation of 1661. The English ordinal, in its general structure, resembles the ancient services used for that purpose, but possesses much greater simplicity, and has some features—e. g., the numerous questions addressed to the candidates—peculiar to itself. There are separate services for the 'making of deacons' and the 'ordering of priests,' but these are practically joined in one, and used on the same day. The service for the consecration of bishops is altogether distinct.

The ordination takes place at one of the Ember seasons, and during the public service, after morning prayer and a sermon on the subject, and begins with the presentation of the candidates by the arch-deacon. The bishop inquires as to their fitness, and commends them to the prayers of the congregation. The litany is then said with special petitions for the candidates for each order, and the communion service commences with a special collect, epistle, and gospel. Between the epistle and gospel, the oath of supremacy is administered, and the candidates for deacons' orders are questioned by the bishop and ordained. The gospel is read by one of the newly-ordained deacons. The candidates for priests' orders are then solemnly exhorted and interrogated, and the prayers of all present are asked for the divine blessing upon them. For this purpose a pause is made in the service for silent prayer. After this the hymn, *Veni Creator Spiritus* (Come, Holy Ghost, our Souls Inspire)—a composition of great antiquity, supposed to be as old as the

4th c.—is sung, and the candidates kneeling before the bishop, he and the assistant presbyters lay their hands upon the head of each, with the words, 'Receive the Holy Ghost for the office and work of a priest in the Church of God,' &c.

The only other ceremony is the presentation of each candidate with the Bible in token of authority to preach; as the deacons had been before presented with the New Testament with authority to read the gospel. The service concludes with the administration of the sacrament of the Lord's Supper.

The consecration of bishops is performed by an archbishop, or some bishop appointed in his place, and two or more of his suffragans, and may take place on any Sunday or holy day. The service is very similar to that for the ordination of priests.

ORDINARIES, or HONOURABLE ORDINARIES, in Heraldry, certain charges composed of straight lines, and in very common use, to which writers on heraldry had assigned abstruse symbolical meanings, but whose real chief peculiarity seems to be that they originally represented the wooden or metal fastenings of the shields in use in actual warfare. The Ordinaries are usually accounted nine—the Chief, Pale, Fess, Bar, Bend, Bend Sinister, Chevron, Saltire, and Cross. Heraldry vary a little in their enumeration, some taking in the Pile in place of the Bar. Each is noticed under a separate article.

ORDINARY, a term used in the British navy in two senses. First, as regards ships, vessels in ordinary are those out of actual use, commonly dismantled, and occasionally roofed over, to protect them from the weather. They are congregated near the several dockyards, where their masts and gear lie ready for their immediate fitting for sea when required. A few men have charge of each vessel; a certain number of vessels constitute a division, with a lieutenant in command; and a line-of-battle-ship, called a 'guard-ship of ordinary,' is responsible for the different divisions at each port. The ships are moored in safe places, as up the Medway, in the recesses of Portsmouth and Plymouth harbours, &c.

As regards men, an *ordinary seaman* is one capable of the commoner duties, but who has not served long enough at sea to be rated as an Able Seaman (q. v.). His pay is 11*d.* a day on entering, and 13*d.* a day on promotion to the first class, or 1*s.* and 1*s.* 3*d.* if engaged for continuous service.

ORDINARY (Lat. *ordinarius*) is the name commonly given to a person, who, in virtue of his office, and in his own consequent right, is competent to do certain acts or to decide certain causes. In this sense, there are many functionaries who may be called by the name ordinary. But the word in canon law, when used without other additions, is understood to mean the bishop, who is the ordinary of his own diocese, and is competent of himself to do every act necessary for its government, and for the ordering of the spiritual concerns of his flock. The jurisdiction of the ordinary is called by that name, in contradistinction to 'extra-ordinary jurisdiction,' which arises from some abnormal circumstances, and from 'delegated' jurisdiction, which is imparted by the ordinary to another person to be exercised vicariously.

In English Law, the ecclesiastical jurisdiction which was formerly vested in bishops and their officers relating to wills and marriages, was recently abolished, and transferred to a new judge, called the Judge Ordinary, who is entirely disconnected with the church. The bishops still retain their jurisdiction in matters of discipline as regards the clergy.—In Scotland, the Judge Ordinary generally

means the sheriff depute or substitute, who has ordinary jurisdiction in the county. Lord Ordinary is the name given to certain judges of the Outer House in the Court of Session.

ORDINARY OF ARMS, in Heraldry, an index or dictionary of armorial coats, arranged, not according to names, like an armory, but according to the leading charges in the respective shields, so as to enable any one conversant with heraldic language, on seeing a shield of arms, to tell to whom it belonged. A very imperfect ordinary for England is appended to Edmonson's *Heraldry*: a far more complete and elaborate work of the same kind, Papworth's *Ordinary of British Armorial*, partly edited by Alfred Morant, was published in 1874.

ORDINATION, the rite or ceremony by which ministers of the Christian Church are dedicated to their sacred office. The use of a ceremonial for such purposes is traceable among the Jews (Exod. xxix. 24, Levit. xxi. 10, Num. iii. 3); and the New Testament contains frequent reference to the specific ceremonial of 'imposition of hands' (Acts vi. 1—7, xiii. 1—4, xiv. 23; 1 Tim. iv. 14, v. 22; 2 Tim. i. 6). In the Roman, the Greek, and the other Eastern Churches, this rite of ordination is held to be sacramental, and it is reserved, at least as regards the major orders (see **ORDERS, HOLY**), exclusively to bishops. In extraordinary cases, it was permitted to cardinals and to certain abbots to confer the minor orders. Considerable controversy exists among Catholic writers as to what are the essential portions (*Materia Sacramenti*) of the rite of ordination. Some place it in the 'imposition of hands,' some in the 'presentation of the instruments' symbolical of each order. The controversy derives some importance from the diversity which exists between the Greek and Roman ceremonial; but on this head Roman Catholics maintain that the essential rites are contained alike in both ceremonials. As regards the *validity* of the rite of ordination, the mere fact of its being conferred by a bishop suffices; but there is not any part of the Roman discipline which is more jealously guarded by laws than the administration of orders. The candidate can only be *lawfully* ordained by 'his own bishop' (*proprius episcopus*), or with the authority of his own bishop, which must be communicated to the ordaining bishop by what are called dimissorial letters. The candidate may be claimed by a bishop as by 'his own bishop' under any of four titles—of birth, of domicile, of benefice, or of connection by personal service; and if an ordination be attempted without some one of these titles, heavy ecclesiastical penalties are incurred as well by the ordainer as by the ordained. On the part of the candidate himself, certain qualifications are required; and certain disqualifications created or propounded by the canon law, called *irregularities*, are held to render an ordination in some cases invalid, and in all unlawful.

In the Church of England and other Reformed Episcopal churches, the rules of the ancient canon-law are retained, by which no one could be ordained without previous examination of his fitness, or who was disqualified by bodily infirmity, illegitimacy, immorality, or simony, or who was unprovided with a title (i.e., an appointment to serve in some church) which should provide him with a maintenance; or who, being a candidate for deacon's orders, was under 20, and for priest's, under 24 years of age; but the age for admission to deacon's orders is changed to 23. A college Fellowship is admitted as a title. (For the ceremony of Ordination see **ORDINAL**.) A person can only be ordained by the bishop in whose diocese he is to serve, except on *letters dimissory* from that bishop to another.

In other Reformed churches ordination is performed by the presbytery, or by one or more ordinary ministers. Some small Protestant denominations have no ceremony of ordination whatever.

ORDNANCE (*ordnance*, primarily, any disposition, arrangement, or equipment; and then applied incidentally to a particular part of the equipment or apparatus of war), a name applied to the guns and munitions of an army generally, and in particular to the great guns. Descriptions of the various sorts of ordnance will be found under **CANNON, FIREARMS, GUN, HOWITZER, MORTAR, RIFLED ARMS.**

ORDNANCE DEPARTMENT, one of the oldest departments under the crown, was abolished by an Order in Council of the 25th May 1855, after an existence of at least 400 years. Its constitution, its important functions, and the causes which led to its dissolution, will be found under **BOARD OF ORDNANCE**. The early history of the department is lost in the middle ages; but it appears to have risen gradually under the Lancastrian kings. A master of the Ordnance is mentioned in the time of Richard III.; but we read of John Louth being Clerk of the Ordnance as early as 1418. Henry VIII. constituted the Board, adding a Lieutenant, a Surveyor, and a Storekeeper, to whom a Clerk of the Cheque was subsequently joined. With the exception of the last, whose office was abolished in the beginning of the present century, this organisation was maintained until the abolition of the whole. In 1604, James I. dignified the Master and Lieutenant with the respective titles of Master-general and Lieutenant-general. The history of the Ordnance Office is of importance in British history, as in all wars it has been responsible not only for the management of the *matériel* of the armies, but also for the direction of the *personnel* of the artillery and engineers. By an Order in Council of June 23, 1870, the Department of Ordnance in a very modified form was revived under the Surveyor-general of the Ordnance, as a section of the War Office, responsible for all supplies and *matériel* of war.

ORDNANCE SELECT COMMITTEE was, until 1870, a committee composed of scientific officers, to advise the Secretary of State for War on all inventions in war *matériel*. It had its offices at Woolwich, in the midst of the manufactories of the Royal Arsenal, and near the headquarters of the royal artillery, by whom most of the designs had to be practically tested. The president of the committee was usually a general officer of artillery; and a captain in the royal navy served as vice-president. Since 1870, these functions have been fulfilled by officers of the Department of the Director of Artillery and Stores, who has his headquarters at the War Office.

ORDNANCE SURVEY. By this term is understood the various operations undertaken by the Ordnance department of the British government for preparing maps and plans of the whole kingdom and its parts. The idea of a general map of the country to be executed by the government was first proposed after the rebellion in 1745, when the want of any reliable map of the northern parts of Scotland was much felt by the officers in command of the royal troops. Its execution was intrusted to Lieutenant-general Watson, the deputy quarter-master of North Britain; but it was mostly carried out by Major-general Roy, an officer of engineers. The drawing, on a scale of one inch and three-fourths to the mile, was completed in 1755; but in consequence of the war which broke out in that year, was never published. In 1763 it was proposed to extend the

survey to the whole kingdom; but the first steps to effect this were taken only in 1784, when Major-general Roy commenced measuring a base-line on Hounslow Heath, near London. This principal triangulation was designed partly for astronomical purposes, and partly as a basis for a map on a small scale. The base-line was remeasured with great care in 1791; and detail plans were commenced by officers of the Royal Engineers, partly for practising them in military drawing, and partly for the purpose of forming plans of some portions of Kent for the use of the Ordnance. The principal object was, however, the instruction of a corps of military surveyors and draughtsmen, the plans themselves being regarded as of secondary importance. In 1794, the survey for the one-inch map was begun, and some sheets were published in 1796. As the series of principal triangles were extended westwards towards the Land's End, it was thought right to measure another base, for verification, on Salisbury Plain in 1794; and two other base-lines were subsequently measured—one in 1801 at Misterton Carr, and the other in 1806 on Ruddian Marsh. Though first intended chiefly as a military map, the publication of the survey soon created a desire on the part of the public for better maps, and surveyors were then hired to hasten its progress. This, however, was very slow, the map being at one time entirely suspended during the war in the beginning of this century, and even the parts which were executed, having been done by contract, were found very inaccurate. In this condition the survey of England continued during the first quarter of the present century, sometimes delayed by the government from motives of economy, at other times urged on by the county gentlemen, who wished the map either as a hunting-map or for local improvements.

In Scotland, the principal triangulation was begun in 1809, but was discontinued in the following year, to enable the persons who had been employed there to carry forward the subordinate triangulation required for constructing the detail maps in England. In 1813 it was resumed, and continued steadily up to 1819; a new base-line having been measured on Belhelvie Links, near Aberdeen, in 1817, and the great sector used at various stations, both on the mainland and in the islands. In 1820 it was again suspended, was resumed in 1821 and 1822, and anew broken off in 1823, the large theodolite being wanted in order to proceed with the principal triangulation in South Britain. In 1824 the survey of Ireland was begun, and nothing more was done in Scotland till 1838, except that some detail surveying for a one-inch map was continued for a few years in the southern counties. The chief strength of the surveying corps was now transferred to Ireland. A map of that country was required for the purpose of making a valuation which should form the basis of certain fiscal arrangements and other improvements which the social evils and anomalies of Ireland urgently demanded. For this map a scale of six inches to the mile was adopted, as best suited for the purposes in view. On this scale the whole map was completed, and published in 1845, though the first portions were in an imperfect form, and needing revision, which was proceeded with in 1873.

In 1838 the triangulation of Scotland was resumed; and the survey of Ireland having been finished in 1840, surveys for a six-inch map were begun for the northern portions of England which had not been mapped on the one-inch scale. In connection with this map, the base-line on Salisbury Plain was remeasured with great accuracy in 1849, and its length found 36577·8581 feet. In 1841, some-

ORDNANCE SURVEY.

secondary operations for a map of Scotland, also on a six-inch scale, were begun; but proceeded so slowly, that in 1850 only the map of Wigtownshire and some parts of Lewis were completed. Much dissatisfaction having been expressed in Scotland by the press and public bodies, as to the slow progress of the map and the six-inch scale on which only it was published, a committee of the House of Commons (Lord Elcho's) recommended the six-inch maps to be stopped, and the one-inch map completed as speedily as possible. This change produced much discussion as to the relative value of the one-inch and six-inch scales then in use, and the expediency of adopting a still larger scale as more valuable to the public. Circulars were issued, asking the opinion of various public bodies, and of scientific and practical men, as to the proper scale for a great national survey. The great preponderance of opinion was in favour of a scale of 1-2500 of nature, or nearly one inch to the acre. This scale was therefore ordered by a treasury minute of 18th May 1855 (Lord Palmerston's), and though subsequently stopped, in consequence of a motion by Sir Denham Norreys in the House of Commons in June 1857, was again recommended by a royal commission (December 1857), and ordered to be resumed by another treasury minute (11th September 1858). In 1861 a select committee was again appointed, and reported that it is desirable that the cadastral survey on the scales directed by the treasury minute of the 18th May 1855 be extended to those portions of the United Kingdom that have been surveyed on the scale of one-inch to the mile only. This recommendation has now been adopted by the government, and the survey is at present proceeding on the following scales: Towns having 4000 or more inhabitants are surveyed on a scale of 1-500 of the linear measurement, which is equivalent to 126·72 inches to a mile, or 41½ feet to an inch; Parishes (in cultivated districts) 1-2500 of the linear measurement, equal to 25·344 inches to a mile, or one square inch to an acre; Counties on a scale of six inches to a mile; Kingdom, a general map one inch to a mile.

The sheets of the one-inch map join together, so as to form a complete map of the whole kingdom. This is true also of the sheets of each county on the six-inch scale, and of each parish on the 1-2500 scale, but the sheets of different counties and parishes are not connected. The 1-2500 scale also applies only to cultivated, populous and mineral districts; the Highlands of Scotland, and other extensive moorland and uncultivated tracts, being only surveyed on the six-inch scale, and published on the one-inch scale.

The scale, originally one inch to a mile, was increased to six inches to a mile when the survey reached Yorkshire and Lancashire; these counties being done on that scale as well as on the one-inch scale. The remaining counties of England were done on the scale of twenty-five inches to a mile for cultivated districts, as well as on the six-inch and one-inch scales. When England was completed, a re-survey was begun on the 25-inch scale of those counties which had only been surveyed on the one-inch scale. The sheets on the scale of twenty-five inches to a mile (called parish maps) are reduced by photography, and issued on the scale of six inches to a mile (county maps). Of some of the maps, two series are issued, one having the hill features marked in the usual way, the other with contour lines only. The area that has been surveyed in England was, at the end of 1880, 34,696 square miles (of a total of about 58,000 square miles). The annual grant for the re-survey was officially stated in 1880 at £133,500.—The survey of the whole of Scotland was completed in 1877, and the maps for a large proportion of the

area have been published.—In Ireland, as stated, the six-inch maps have been long published, and are now in process of revision. A one-inch map of the whole in outline has been published, and is being completed by the addition of hills. The engraving of hills in the remainder is also being proceeded with. In all the three kingdoms, plans of many of the towns on the 10 and 5 feet scale are also published.

The sketch now given of the history of this great national undertaking will shew that it has been conducted at different times on different scales and plans, and that the system now pursued was only adopted after much discussion both in parliament and out of doors. The map was originally begun as a military map, and the scale of one inch to the mile chosen, without considering whether some other scale would not offer greater advantages. Many now think that a scale a little larger, and an aliquot part of nature, such as 1-50,000, or about 1¼ inch to the mile, would have been preferable for the small map; in which case a scale of 1-10,000 of nature, or about 6½ inches, might have been chosen for the intermediate, instead of the six-inch scale selected at first for mere local purposes in Ireland. Be this as it may, the arguments in favour of the one-inch map are, that it is the most convenient both as a general and travelling map. For general views of the structure of a country, the distribution and relations of its mountains, plains, valleys, and rivers, the one-inch is admitted to be superior to the six-inch, and thus better adapted in the first instance for laying out roads, railways, or other extensive public works, or for the publication of a general geological survey. Such a map, on the other hand, is on too small a scale to admit of correct measurements of small distances; it is in some respects a generalised picture, and not a correct plan. The six-inch maps were at first selected in Ireland as the smallest size on which correct measurements of distances and areas could be made. On them every house and field, and almost every tree or bush, might be laid down. Hence they are superior for working out details, as in minute surveys of railways or roads, or the complex geological structure of rich mineral districts. On such sheets, too, a proprietor or farmer may find every field laid down, and the relative heights indicated by contour lines, and may therefore use them for drainage and other improvements. It has also been proposed to use these six-inch maps as a record of sales or encumbrances of land, thus lessening the cost and simplifying the transfer of property. On the other hand, their size unfits them for most of the purposes for which the one-inch map is useful, and the contour lines give a far less vivid and correct impression of the physical features of a country than the hill sketching of the one-inch map. Most of the purposes of the six-inch plans are attained in a still more perfect manner from the 25-inch plans or cadastral survey. This last name is taken from the French *cadastre* (a register of lands), and is defined (in the *Recueil des Lois, &c.*) as a plan from which the area of land may be computed, and from which its revenue may be valued. The purposes to which these large plans may be applied are, as estate plans, for managing, draining, and otherwise improving land, for facilitating its transfer by registering sales or encumbrances; and as public maps, according to which local or general taxes may be raised, and roads, railways, canals, and other public works, laid out and executed.

Nearly all the states of Europe have produced trigonometrical surveys, many of them of great excellence as scientific works. All of these have

been published, or are in course of publication, on convenient scales; generally smaller than one inch to a statute mile. The most important of these are:

Austria and Northern Italy, scale $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile.
 Bavaria, Baden, Wurtemberg, and the Hesse territories $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile.
 Belgium, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile.
 Denmark, survey map in preparation.
 ———, Iceland, surveyed and published on different scales.
 France, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile; and a reduction to $\frac{1}{100,000}$ or 5 miles to an inch.
 Great Britain, 1 inch, 6 inches, and, in the lowland districts, 25 inches to a mile; and the coast survey, general charts, $\frac{1}{2}$ miles to an inch; harbours and bays, from 2 inches to 12 inches to a mile.
 Hanover and East Prussia, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile.
 Italy (see Sardinia, Tuscany, &c.), survey maps of Naples, Rome, &c., in progress.
 Greece (French survey) $\frac{1}{100,000}$ or $\frac{1}{4}$ ths miles to an inch.
 Netherlands, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths inches to a mile.
 Prussia, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile, and many smaller.
 Russia, survey map in progress.
 Sardinia, $\frac{1}{100,000}$ or $\frac{1}{4}$ th of an inch to a mile.
 Saxony, $\frac{1}{100,000}$ or $\frac{1}{4}$ th inches to a mile.
 Switzerland, $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile.
 Spain and Portugal, surveys commenced.
 Sweden and Norway, surveys in progress.
 Tuscany, $\frac{1}{100,000}$ or about 3 miles to an inch.

The great Trigonometrical Survey of India, which was begun more than 70 years ago, has been conducted with great ability. The year 1880–81 witnessed the completion of the principal triangulation of all India, the only remaining gap being then filled in. The maps are published on a scale of $\frac{1}{100,000}$ or $\frac{1}{4}$ th of an inch to a mile. In America, the Coast Survey of the United States is a work of enormous extent, great accuracy, and minute detail. The general charts are published on a scale of $\frac{1}{100,000}$ or $\frac{1}{4}$ ths of an inch to a mile; the harbours and ports $\frac{1}{100,000}$ or $\frac{1}{4}$ th of an inch to a mile. A vastly greater undertaking, the triangulation of the whole area of the republic, has been more recently begun.

The Geological Survey, though under a different department of government (Science and Art), may be shortly noticed here. The English survey, begun in June 1835, is now completed on the scale of one inch to a mile (solid geology), and the Drift survey is being proceeded with. The Irish survey was begun in 1840, but was subsequently suspended till 1845. It is now completed, with the exception of a part of Donegal. In 1854, the survey was extended to Scotland, and now extends over the counties of Edinburgh, Haddington, Fife, Kinross, Linlithgow, Peebles, Lanark, Ayr, Renfrew, Dumfries, Stirling, Perth, Forfar, Kincardine, Aberdeen, Banff, Elgin, Wigton, Kirkcudbright, Dumfries, Selkirk, Berwick, and Roxburgh. The surveys are made on the six-inch maps in the parts of the country where these exist, but the results are published on the one-inch scale only, except some of the coal-fields, which are issued also on the six-inch scale. Besides the maps, sheets of sections, horizontal and vertical, with valuable memoirs, and monographs on fossils, are also published. A survey of the West Indies has been carried out, and memoirs descriptive of the geology of Trinidad, Jamaica, and British Guiana have been published. The geological survey of Canada and that of India are vast undertakings in progress.

O'REGON, one of the United States of America, in lat. 42° – 46° N., long. 116° $40'$ – 124° $25'$ W., bounded N. and E. by Washington, from which it is chiefly separated by Columbia River; E. by Idaho, the Lewis or Snake River intervening; S. by Nevada and California; and W. by the Pacific Ocean; being

350 miles from east to west, by 275 from north to south, with an area of 96,030 sq. m. The principal rivers are the Columbia, and its branches—the Willamette, Fall River, Snake River, and the Owyhee. The Columbia is a large river, navigable 96 miles to the Cascade Mountains, through which it passes, but the entrance is difficult. The Willamette drains a large and fertile valley between the mountains and the ocean. The Cascade Mountains, which have extinct volcanic peaks of 4000 to 10,000 feet high, run north and south, dividing the state into two unequal regions. The western third of the state, bordering the Pacific, has a mild, equable, and moist climate, with valleys of great fertility, where pines grow from 250 to 300 feet high, and firs from 4 to 10 feet in diameter. The rainfall at Astoria, mouth of the Columbia River, is 86 inches. East of the mountains, the climate is dry and variable, and the soil less fertile. Gold and silver are found in the Cascade Mountains, with copper, platinum, iridium, and osmium. Coal has been discovered on Coose Bay. The chief agricultural productions are wheat, oats, potatoes, and apples. The great forests abound with the grisly and black bear, panther, wild-cat, elk, deer, antelope; among the birds are the California vulture, golden eagle, American swan, Canadian goose, &c.; while the rivers swarm with salmon. There were, in 1880, 26 organised counties. Most of the settlements are on the Columbia River and in the Willamette Valley. The chief towns are—Salem, the capital, on the Willamette River, pop. 4000; Portland, 8300; and Oregon City, about 2000. Within the state are about 1700 Indians and 9500 Chinese. Four colleges have been founded, 1 medical school, numerous academies, common schools, daily and weekly papers, and churches of several denominations. O. was the name formerly given to the whole territory west of the Rocky Mountains, claimed by the United States, as far north as lat. 54° $40'$ N. This claim was resisted by the British government, which asserted a right to the entire territory, and in 1818 a treaty was made, and renewed in 1827, giving joint occupation, which was terminated in 1846 by notice from the United States government, and the question seemed likely to involve the two countries in war, when a compromise was offered by Lord Aberdeen, on the part of the British government, and accepted by that of the United States, by which the boundary was settled on the 49th parallel. The northern portion is now Washington, and the eastern Idaho Territory. The coast was discovered, and Columbia River entered, in 1792. In 1811, Astor (q. v.) founded Astoria as a fur dépôt. The territory was organised in 1848, and in 1859 O. was admitted as a state. In the 12 years preceding 1883, the population of the state doubled; the wheat exports increased tenfold (from \$600,000 to \$6,000,000); a large trade developed in red pine timber; and tinned salmon exports came to be worth \$3,000,000 per annum. The climate of O. has been compared to that of the south of France. Pop. (1860) 52,464; (1870) 90,776; (1880) 174,768.

OREIDE, a new alloy lately introduced by the French as a substitute for ormolu, which it excels in its gold-like character. There are two formulas for composing it. In the first the ingredients are: copper, 100·0; tin, 17·0; magnesia, 6·0; sal ammoniac, 3·6; quicklime, 1·80; argols, or unrefined tartar, 9·0. In the second, zinc is substituted for the tin. The latter does not possess the same brilliancy as the former. The metals are first melted, and the other ingredients, after being thoroughly incorporated together by powdering and mixing, are slowly added, and the whole is kept in a state of fusion for about an hour, and the scum removed from time to time.

OREL, a government in the south-west of Central Russia, bounded on the W. by Little Russia and the government of Smolensk. Area, 17,951 square miles; pop. (1880) 1,826,169. The surface is flat, with rising grounds in the vicinity of the towns of Kromy and Malo-Archangelsk, from which the Oka and Sosna respectively take their rise. The government is drained by the Desna on the west, an affluent of the Dnieper; the Oka on the north, an affluent of the Volga; and the Sosna on the east, an affluent of the Don. The soil is fertile, and the climate mild. The western part of the government abounds in woods. In the district of Briansk, in the north-west, there are a number of iron mines. Agriculture and the cultivation and preparation of hemp are the chief employments of the people. Corn is very extensively grown, and great quantities are sent to St Petersburg, Riga, and the Black Sea ports for export. The principal article of export is wheat, in grain and in flour. Sail-cloth, rope and hemp-yarn manufactures are carried on; glass and iron works are numerous. The hemp of O. is reckoned the best in Russia; and the oil obtained from hemp-seed, and used in Russia as an article of food, is extracted at 2000 mills. The rearing of cattle and horses is much attended to; almost all the considerable landowners keep studs.

OREL, a thriving town of Great Russia, capital of the government of the same name, stands on the Oka, at its confluence with the Orlik, 226 miles south-south-west of Moscow, and 678 miles south-south-east of St Petersburg. It was founded in 1566, as a stronghold in defence of what was then the Russian frontier, against the inroads of the Tartar tribes of the Crimea. Its importance as a fortress ceased after the annexation of Little Russia, and it then became a commercial town. The town owes much to its advantageous position on a navigable river in the midst of the most fertile provinces of Russia. The railway from Moscow to Odessa, on the Black Sea, passes through O., and the Vitebsk line affords it direct railway communication with the port of Riga, and thus its export trade has been greatly promoted. It is the seat of a bishop, and contains numerous churches; its houses are for the most part constructed of wood. There is an important ferry here over the Oka. The chief manufacturing establishments in the town are yarn and rope factories. The principal articles of export are cereals and hemp. On the 7th June 1848, O. suffered severely from a great fire, which destroyed 1237 houses, four bridges, and a number of granaries. Pop. (1880) 53,500.

ORELLI, JOHANN KASPAR, an eminent philologist and critic, was born at Zürich, 13th February 1787. His father was long the *Landvogt* of Wädenschweil. He studied in the *Carolinum* at Zürich, and betook himself enthusiastically to the study both of the ancient and of modern languages and literature. In 1806, he was ordained as a clergyman. He spent some years as a tutor at Bergamo; and while there, published, in 1810, two parts of a work entitled *Beiträge zur Geschichte der Ital. Poesie*. In 1813, he became a teacher in the cantonal school at Chur; in 1819, Professor of Eloquence and Hermeneutics in Zürich; and after the foundation of the Zürich High School, in which he took an active part, he was one of its chief ornaments. There never was a man more zealous in the cause of education. It was during this latter and most distinguished period of his career that he produced most of his learned works, and trained to a correct knowledge of antiquity a numerous band of scholars. His political sympathies and opinions were not,

however, confined to the ancient world; he took the liveliest interest in the struggles of Greece for freedom, and in the political reformation of his native country. He died 6th January 1849. O. edited many classical authors with great learning, taste, and acute discrimination; in particular, his editions of Horace (2 vols. Zür. 1837—1838), Tacitus (2 vols. Zür. 1846—1847), and Cicero (4 vols. Zür. 1828—1831) deserve mention; also an *Onomasticon Tullianum* (3 vols. Zür. 1836—1838), executed in association with Baiter, and an *Inscriptionum Latinarum Selectarum Collectio* (2 vols. Zür. 1828).

O'RENBURG, a Russian government in the Ural region, lies partly in Europe and partly in Asia, and extends between the governments of Tobolsk on the N.E. and Samara on the S.W. Area of the government, 73,600 square miles; pop. (1880) 1,070,420. The government is divided into four districts—Orenburg, Verchne Ural'sk, Ovsak, and Troitsk and Tchelabinsk. Capital, Orenburg (q.v.). Till 1865, O. comprised within its area the whole of what is now the distinct government of Ufa (q.v.); but in that year the part of O. lying to the north-west of the Ural mountain range was organised into the new government. The population, the surface, soils, flora, and fauna of this extensive country are of the most various kinds. The government is one of the most elevated in the empire; but it also contains extensive low-lying tracts and steppes. It is traversed by numerous navigable rivers, by means of which and by canals it is in communication with the Caspian and Baltic Seas, and with the Arctic Ocean. The main streams are the Bielaia (running into the Kama, a tributary of the Volga), the Tobol, and the Ural. As many as 2300 larger and smaller lakes lie within the frontiers. Of the whole area, about three-tenths are forest, a half is waste land, and only about a twentieth part is cultivated. The hill country has much pleasant scenery, but great tracts of the steppe regions are utterly barren and desolate. The inhabitants are made up of Russians, Bashkir, Tartar, and Kirghis tribes, Kal-mucks and certain Finnish peoples, with a few Germans. The trade is chiefly with Bokhara, Khiva, Tashkend, and the Kirghis; the exports are gold, silver, and other metals, corn, skins, and manufactured goods; the imports, cattle, cotton—the demand for and supply of which have greatly increased since the commencement of the American war—and the other articles of Asiatic trade. The imports are either disposed of to Russian merchants in the custom-house on the frontier, or are carried by Asiatic traders into Russia, and sold at the great national market of Nijni-Novgorod. There are in the province numerous iron and copper works, as well as valuable gold diggings, both belonging to the crown and to private individuals. The salt mines are valuable. There is a small-arms factory on a large scale, and a few other factories. Cattle-breeding is very extensively carried on. The number of horses in O. is larger than in any other Russian government. The southern frontiers are defended, at intervals of 12 or 15 miles, by fortified settlements, inhabited by Cossacks; those on a larger scale being surrounded by a bulwark and a moat. This line of forts extends over a frontier of 2000 miles eastward to the boundaries of China; the series from the mouth of the Ural to the Tobol, occupied by upwards of 242,000 Ural and Orenburg Cossacks, being known as the Orenburg line. The region of which O. forms part was originally called Bashkir-land, and became subject to the Czar of Moscow in 1556. Besides the towns giving name to the governmental districts, the only other place of consequence is Mijaak.

ORENBURG, a town on the eastern frontier of European Russia, in the government of the same name, on the river Ural, 1393 miles south-east of St Petersburg. The town, which dates from 1742, suffered from a great conflagration in 1879. Pop. (1890) 47,840. It is the centre of the governor-generalship of the government of the same name, has an excellent custom-house, and carries on an extensive trade with Khirghiz and other Asiatic tribes. It imports cotton, silk-stuffs, and shawls from Bokhara, Khiva, and Tashkent; tea (brought mostly on camels) from China; and sheep and cattle from the Kossacks and Khirghiz. The sheep are killed in autumn for the fat and skins, which are purchased by Russian merchants. Corn, skins, and metals are the principal exports. In the neighbourhood is the very rich rock-salt mine of Iletak. At O. the Ural is frozen from October till March.

OREODA'PHNE, a genus of trees of the natural order *Lauraceæ*, sometimes called **MOUNTAIN LAUREL**. The fruit is succulent, partly immersed in a deep thick cup formed of the tube of the calyx. *O. opifera* is a native of the countries on the lower part of the Amazon. A volatile oil obtained from the bark is used as a liniment, and when kept for a short time deposits a great quantity of camphor.—*O. cupularis* is a very large tree with strong-scented wood, the bark of which yields the cinnamon of Mauritius. It grows also in Bourbon and Madagascar.—*O. foetens*, a native of the Canaries, has wood (*Til-wood*) of a most disagreeable odour. *O. bullata*, found at the Cape of Good Hope, is also remarkable for the disagreeable odour of its wood, the *Stink-wood* of the colonists; but it is hard, durable, beautiful, takes an excellent polish, and is used in ship-building.

ORES. Any mineral or combination of minerals containing as much metal as to be profitably extracted, is reckoned by miners an ore. The proportion necessary for this purpose is, of course, very various, according to the value of the particular metal and the facility or difficulty of *reducing* the ore. A rock containing only 1 per cent. of iron is never called an ore; one containing the same proportion of gold is a very rich ore. Metals rarely exist in ores in a pure or native state; they are almost always chemically combined with oxygen, sulphur, or other elements.

Ores present themselves in a multiplicity of forms and positions in the solid crust of the earth. Sometimes they are sprinkled through the whole mass of the rocks in which they occur, as is often the case with gold, tin ore, and magnetic iron ore. Sometimes they are deposited in regular parallel beds between the strata of other rocks, as in the case of many iron-stones and of cupreous schist. At other times, they occur in irregular lumps or concretions; or they fill up the fissures of other rocks, forming veins, particularly silver, copper, and lead ores; or lastly, they are found in detritus, gravel, sand, and other alluvial deposits. This last form is evidently the result of disturbance and transport from some of the other positions above specified. And as the metallic parts of the mineral masses or rocks so disturbed and transported are the heaviest, and are insoluble in water, they are more concentrated in these deposits than in their original position, and can therefore be extracted with greater advantage. Such deposits are called *washings*, from the metal being separated from the other debris by the process of washing. Gold and platinum are mostly got in this way in the Ural and Altai Mountains, and gold in Guiana, California, and Australia. Tin ore is also found in alluvial deposits in Cornwall and India. The

reduction of ores is treated of under **METALLURGY** and the names of the several metals.

ORFILA, **MATEO JOSÉ BONAVENTURA**, a celebrated physician and chemist, and the recognised founder of the science of toxicology, was born at Mahon in Minorca, 24th April 1787. His father, who was a merchant, intended that his son should follow the same pursuit; but young O. shewed so strong a predilection for the study of medicine, that all thoughts of a mercantile career for him were dismissed, and he was sent to the medical schools of Valencia and Barcelona. In the latter of these seminaries, he so distinguished himself, that the junta of the province resolved to defray the expense of his further education in Paris, on condition of his returning to Barcelona to fill one of the chairs in their medical school; and accordingly O. departed for Paris in 1807. The junta were prevented from fulfilling the agreement by the outbreak of war with France; but O., who had now made many friends in Paris, was enabled to continue his studies. In October 1811, he received the degree of Doctor of Medicine, and immediately commenced a private course of lectures on chemistry, botany, and anatomy, which was largely attended, and, along with his successful practice, soon rendered him famous. In 1813 appeared the first edition of his celebrated work on poisons, entitled *Traité des Poisons tirés des Règnes Minéral, Végétal, et Animal, or Toxicologie Générale* (Paris). The work was commended by the Institute, and rapidly passed through a number of editions. In 1816, on the occasion of a short visit to Minorca, he met with an enthusiastic reception; and on his return to Paris, became court physician. In 1819, he was created a citizen of France, and became professor of jurisprudence; and in 1823, was transferred to the chair of chemistry, to which, in 1831, was added the deanship of the faculty. His prosperity was now at the full; his lectures were more popular than ever; his works were reckoned as master-pieces; and he himself, by the geniality of his disposition and his many accomplishments, was a universal favourite in society. In all cases of suspected poisoning, he was a most important witness. From 1834, he was a member of the council of public instruction, and procured the passing of many useful measures, such as the creation of secondary medical schools, and the multiplication of means of instruction and observation. He also organised the clinical hospital, founded a new botanic garden, and a museum of comparative anatomy, which is now known by his name. On the outbreak of the revolution of 1848, he was deprived of his place in the medical faculty on account of his conservative opinions, but retained his professorship. He died at Paris, March 12, 1853. His great work on toxicology has gained for him undying fame; it is a vast mine of information, the result of the author's solitary indefatigable researches; and includes symptoms of poisoning of all kinds, the appearances in the body to which poisons give rise, their action, and the means for their detection. It is well written, and exhibits the accuracy of language equally with the sound judgment of its author. His other works are not nearly so famous, partaking more of the character of compilations; the chief of them are—*Elémens de Chimie appliqués à la Médecine* (Paris, 1817; 8th edition, 1851); *Traité de Médecine Légale* (1823—1825; 4th edition, 1847); *Mémoires sur Plusieurs Questions Médico-légales* (Paris, 1839); and *Recherches sur l'empoisonnement par l'Acide Arsenieux, &c.* (Paris, 1841). He also contributed largely to various journals, dictionaries, encyclopedias, and other periodicals. He has left a number of Memoirs, which have not yet been published.

ORGAN (Gr. *organon*, a contrivance requiring skill on the part of the user of it), a musical instrument played by finger-keys, and in general partly also by foot-keys, and consisting of a large number of pipes of metal and wood made to sound by a magazine of wind accumulated by bellows, and admitted at will by the player. The following description is necessarily restricted to the most fundamental arrangements of this very complicated instrument. As met with in cathedrals and large churches, the organ comprises four departments, each in most respects a separate instrument with its own mechanism, called respectively the *great-organ*, the *choir-organ*, the *swell-organ*, and the *pedal-organ*. Each has its own clavier or keyboard, but the different claviers are brought into juxtaposition, so as to be under the control of one performer. Claviers played by the hands are called *manuals*; by the feet, *pedals*. Three manuals, belonging to the choir, great, and swell organs respectively, rise above each other like steps, in front of where the performer sits; while the pedal-board by which the pedal-organ is played is placed on a level with his feet. The condensed air supplied by the bellows is conveyed through wooden tubes or trunks to boxes, called *wind-chests*, one of which belongs to each department of the organ. Attached to the upper part of each wind-chest is a *sound-board*, an ingenious contrivance for conveying the wind at pleasure to any individual pipe, or pipes, exclusively of the rest. It consists of two parts, an *upper board* and an *under board*. On the upper board rest the *pipes*, of which a number of different quality, ranged behind each other, belong to each note. In the under board is a row of parallel *grooves*, running horizontally backwards, corresponding each to one of the keys of the clavier. On any of the keys being pressed down, a valve is opened which supplies wind to the groove belonging to it. The various pipes of each key stand in a line directly above its groove, and the upper surface of the groove is perforated with holes bored upwards to them. Were this the whole mechanism of the sound-board, the wind, on entering any groove, would permeate all the pipes of that groove; there is, however, in the upper board, another series of horizontal grooves at right angles to those of the lower board, supplied with *sliders*, which can, to a small extent, be drawn out or pushed in at pleasure by a mechanism worked by the *draw-stops* placed within the player's reach. Each slider is perforated with holes, which, when it is drawn out, complete the communication between the wind-chest and the pipes: the communication with the pipes immediately above any slider being, on the other hand, closed up when the slider is pushed in. The pipes above each slider form a continuous set of one particular quality, and each set of pipes is called a *stop*. Each department of the organ is supplied with a number of stops, producing sounds of different quality. The *great-organ*, some of whose pipes appear as show-pipes in front of the instrument, contains the main body and force of the organ. Behind it stands the *choir-organ*, whose tones are less powerful, and more fitted to accompany the voice. Above the choir-organ is the *swell-organ*, whose pipes are enclosed in a wooden box with a front of louvre-boards like Venetian blinds, which may be made to open and shut by a pedal, with a view of producing *crescendo* and *diminuendo* effects. The *pedal-organ* is sometimes placed in an entire state behind the choir-organ, and sometimes divided, and a part arranged on each side. The most usual compass of the manuals is from C on the second line below the bass staff, to D on the third space above the treble staff; and the compass of the

pedals is from the same C to the D between the bass and treble staves. The real compass of notes is, as will be seen, much greater.

Organ-pipes vary much in form and material, but belong to two great classes, known as *mouth-pipes* (or *flute-pipes*) and *reed-pipes*. A section of one of the former is represented in the figure. Its essential parts are the foot *a*, the body *b*, and a flat plate *c*, called the *language*, extending nearly across the pipe at the point of junction of foot and body. There is an opening, *d*, in the pipe, at the spot where the language is discontinuous. The wind admitted into the foot rushes through the narrow slit at *d*, and, in impinging against *c*, imparts a vibratory motion to the column of air in the pipe, the result of which is a musical note, dependent for its pitch on the length of that column of air, and consequently on the length of the body of the pipe: by doubling the length of the pipe, we obtain a note of half the pitch, or lower by an octave. Such is the general principle of all mouth-pipes, whether of wood or of metal, subject to considerable diversities of detail. Metal pipes have generally a cylindrical section; wooden pipes, a square or oblong section. A mouth-pipe may be stopped at the upper end by a plug called a *lompion*, the effect of which is to lower the pitch an octave, the vibrating column of air being doubled in length, as it has to traverse the pipe twice before making its exit. Pipes are sometimes half-stopped, having a kind of chimney at the top. The *reed-pipe* consists of a reed placed inside a metallic, or occasionally a wooden pipe. This reed is a tube of metal, with the front part cut away, and a tongue or spring put in its place. The lower end of the spring is free, the upper end attached to the top of the reed; by the admission of air into the pipe, the spring is made to vibrate, and in striking either the edge of the reed or the air, produces a musical note, dependent for its pitch on the length of the spring, its quality being determined to a great extent by the length and form of the pipe or bell within which the reed is placed. When the vibrating spring does not strike the edge of the reed, but the air, we have what is called the *free reed*, similar to what is in use in the Harmonium (q. v.). To describe the pitch of an organ-pipe, terms are used derived from the standard length of an open mouth-pipe of that pitch. The largest pipe in use is the 32-foot C, which is an octave below the lowest C of the modern pianoforte, or two octaves below the lowest C on the manuals and pedal of the organ: any pipe producing this note is called a 32-foot C pipe, whatever its actual length may be. By a 32-foot or 16-foot stop, we mean that the pipe which speaks on the lowest C on which that stop appears, has a 32-foot or a 16-foot tone.

The *stops* of an organ do not always produce the note properly belonging to the key struck; sometimes they give a note an octave, or, in the pedal-organ, even two octaves lower, and sometimes one of the harmonics higher in pitch. *Compound* or *mixture stops*, have several pipes to each key, corresponding to the different harmonics of the ground-tone. There is an endless variety in the number and kinds of stops in different organs; some are, and some are not continued through the whole range of manual or pedal. Some of the more important stops get the name of *open* or *stopped diapason* (a term which implies that they extend throughout the whole compass of the clavier); they are for the most part 16-feet, sometimes 32-feet stops; the *open diapason* chiefly of metal, the *close* chiefly of wood. The *dulciana* is an 8-foot manual

stop, of small diameter, so called from the sweetness of its tone. Among the reed-stops are the *clarion*, *oboe*, *bassoon*, and *vox humana*, deriving their names from real or fancied resemblances to these instruments and to the human voice. Of the compound-stops, the most prevalent in Britain is the *sesquialtera*, consisting of four or five ranks of open metal pipes, often a 17th, 19th, 22d, 26th, and 29th from the ground-tone. The resources of the organ are further increased by appliances called *couplers*, by which a second clavier and its stops can be brought into play, or the same clavier can be united to itself in the octave below or above.

Organs are now generally tuned on the equal temperament. See TEMPERAMENT. The notation for the organ is the same as for the pianoforte, in two staves in the treble and bass clefs; but in old compositions, the soprano, tenor, and alto clefs are used.

Instruments of a rude description, comprising more or less of the principle of the organ, seem to have existed early. Vitruvius makes mention of a hydraulic organ, but his description is not very intelligible. The organ is said to have been first introduced into church music by Pope Vitalian I. in 666. In 757, a great organ was sent as a present to Pepin by the Byzantine emperor, Constantine Copronymus, and placed in the church of St Corneille at Compiègne. Soon after Charlemagne's time, organs became common. In the 11th c., a monk named Theophilus wrote a curious treatise on organ-building. But it was not till the 15th c. that the organ began to be anything like the noble instrument which it now is. The family of the Antignati, in Brescia, had a great name as organ-builders in the 15th and 16th centuries. The organs of England were also in high repute, but the puritanism of the civil war doomed most of them to destruction; and when they had to be replaced after the Restoration, it was found that there was no longer a sufficiency of builders in the country. Foreign organ-builders were therefore invited to settle in England, the most remarkable of whom were Bernhard Schmidt (generally called Father Smith) and his nephews, and Renatus Harris. Christopher Schreider, Snetzler, and Byfield succeeded them; and at a later period, Green and Avery, some of whose organs have never been surpassed in tone. The largest English organs are those of York Cathedral; Birmingham Town Hall; Christ Church, London; the Royal Albert Hall; and the instrument completed in 1876 for the Hall, Primrose Hill, London. The latter surpasses in size the famous Haarlem organ, long reckoned the largest in the world, which is 103 feet high and 50 broad. The German organs are remarkable for preserving the balance of power well among the various masses, but in mechanical contrivances they are surpassed by those of England.

For a full account of the structure of the organ, see Hopkins and Rimbault, *The Organ, its History and Construction* (Lond. 1855). Rink's *Praktische Orgelschule*, Leipzig, v. y., is the best work on organ playing. See also Dr Stainer's *The Organ* (1877).

ORGAN, ORGANIC, ORGANISM. The word *organ* is derived from the Greek *organon*, an instrument, and is sometimes employed almost in its original sense. But it has received a signification more peculiarly its own, and with which alone the word *organism* is connected, as the designation of any of the parts or members of a living body, the *organism* being the living whole, animal or vegetable, which these organs compose. The idea of an organism or of organisation is almost as much involved in obscurity and difficulty as that of *life*, with which it is so closely connected. But it is observable that a living body is entirely composed

of organs, and these themselves of other organs, until we come to elementary cells; and also, that all the parts are mutually dependent on each other; and therefore an organism has been defined as a natural whole, in which all the parts are mutually to each other means and end. The juice which nourishes a plant is elaborated by the plant itself, although the supplies are drawn from without. The leaves of a plant are produced by the stem, but re-act upon the stem in promoting its growth. This mutual dependence of parts strongly distinguishes an organism from a *machine*, in which the parts concur for a common end, to which each contributes in its own way, but in which each does not contribute to the support of all or any of the rest. In organisms, moreover, besides this support and maintenance of the different parts or organs, there is a provision for the production of new organisms of the same kind, the reproduction or propagation of the species, to which there is nothing analogous beyond the sphere of organic life. Amongst organic beings, as we ascend in the scale from the lowest kinds of plants and animals to the highest, we observe an increasing number of organs and of functions of organs. In the animal kingdom, organic life appears as possessed of sensation and spontaneous motion; whilst plants are limited to growth, assimilation, and propagation. The question as to the nature of organic processes connects itself with a most difficult question as to the relation of chemical processes with psychical functions, chemical processes being certainly carried on, but singularly modified or directed by the living powers of the organic being.—The term *organic* is frequently applied to those things in which an analogy is traced to living creatures, in the mutual dependence of parts. Such an analogy may be traced in social life and in political life; and the more perfectly this relation of mutual dependence or mutual usefulness is established, the better is the state of things, social or political. It is also the highest praise of a work of art, that it suggests this idea of an organic relation of its parts to each other, and to the whole.—*Organic Laws* are those which are fundamental or most essential to the system to which they belong.

ORGANIC ANALYSIS. When a complex organic substance is submitted to chemical examination, the first point is to determine its *proximate* constituents, or, in other words, the several definite compounds of which it is made up. Opium, for example, is thus found to have as its proximate constituents meconic acid, morphia, codeia, and some ten or twelve other substances. The modes by which these proximate constituents are separated are various; the chief being the action of certain solvents, such as ether, alcohol, and water, which extract some of the materials and leave others undissolved. Thus ether is the special solvent of fatty and waxy matters, resins, and camphors; alcohol dissolves the same substances with less facility, but on the other hand takes up many substances which are insoluble in ether; while water, which scarcely acts upon the above-named matters, dissolves saccharine, gummy, and starchy matters, and salts of organic acids. The proximate constituents being thus determined, the next point is to determine their qualitative and quantitative (or ultimate) composition; and it is to these processes—especially the last—that the term *organic analysis* is for the most part restricted.

Qualitative Analysis.—It is shewn in the article ORGANIC COMPOUNDS, that the ordinary ingredients for which we must seek are carbon, hydrogen, oxygen, nitrogen, and sulphur. Carbon and hydrogen may be simultaneously detected by burning the compound (which must be previously well dried) in

a glass-tube in contact with oxide of copper, which readily yields up its oxygen. The carbon is thus converted into carbonic acid, which if passed into baryta water forms a white precipitate of carbonate of baryta, and the hydrogen into water, which collects in drops in a small cooled receiver attached to the tube. Carbon may also be usually recognised by the black residue which almost always remains on burning an organic matter, especially in a narrow test-tube in which there is little air. The presence of nitrogen may in most cases be readily ascertained by heating a portion of the substance in a test-tube with an excess of hydrate of potash, when a distinct odour of ammonia is perceived. Sulphur is detected by igniting the compound with hydrate of potash and nitre, whereby sulphuric acid is formed; and phosphorus and arsenic may be detected by the same means. The presence of oxygen cannot, as a general rule, be directly determined.

Quantitative Analysis.—The first attempts to determine the quantitative composition of organic bodies were made, more than half a century ago, by Gay Lussac and Thenard. The process originally proposed by them has been modified and improved by various chemists, especially by Berzelius, Prout, and Liebig, and it is mainly owing to the great simplifications introduced by the last-named chemist, and to the consequently increased facility of conducting an ultimate analysis, that our knowledge of the composition of organic bodies has so vastly enlarged during the last twenty years.

The operation is always effected by causing complete combustion of a known weight of the body to be analysed, in such a manner that the carbonic acid and water which are formed in the process shall be collected, and their quantities determined, from which, of course, the carbon and hydrogen they respectively contain may be readily calculated. The apparatus required for the analysis of a compound containing carbon, hydrogen, and oxygen

a, b, the combustion tube; c, the central portion, in which the mixture to be analysed is placed; d, the bulb-tube, containing chloride of calcium; e, Liebig's potash apparatus; f, a movable iron screen; g, bricks supporting h, the furnace.

only, consists of (1) a *combustion tube*, composed of hard white Bohemian glass, having a diameter of half an inch or less, and a length of from 14 to 18 inches. One end is drawn out in a point and closed, while the edges of the other (or open) end are made smooth by fusion in the blow-pipe flame. (2) A thin sheet-iron furnace, in which the tube is placed and supported during combustion. (3) A small light tube (which may be either a bulb-tube, as in the figure, or a U-tube), which is filled with fragments of spongy chloride of calcium to absorb the watery vapour that is driven through it; and (4) Liebig's bulb-apparatus, containing a solution of potash of specific gravity 1.27, for the purpose of absorbing the carbonic acid. The chloride-of-calcium tube is connected by a well-dried perforated cork to the open extremity of the combustion tube, and by a little tube of flexible caoutchouc, secured by silk cord, to the potash apparatus.

In performing an analysis a little freshly prepared oxide of copper is first introduced into the combustion tube, then a mixture of about 5 grains of the substance to be analysed, with an excess of

the oxide, while the tube is lastly filled to within an inch of its open mouth with the oxide alone. The tube is then placed in the furnace, which may be heated with charcoal or gas. Red-hot charcoal is now placed round the anterior part of the tube, containing the pure oxide of copper; and when this is red-hot, the fire is slowly extended towards the further extremity by shifting the movable screen shewn in the figure. When the tube has been completely heated from end to end, and no more gas is disengaged, the charcoal is gradually removed from the further extremity of the tube, and the point of the latter broken off; after which a little air, freed from moisture and carbonic acid, is drawn through the whole apparatus, so as to secure any carbonic acid and watery vapour remaining in the tube. The parts are then detached, and the increase of weight of the chloride-of-calcium tube and of the potash apparatus is determined by an accurate balance. Gas furnaces of various construction have now taken the place of the charcoal furnaces, and several other minor improvements and refinements have been introduced, but the method remains in all essential points what Liebig made it. The following analysis of crystallised cane-sugar will illustrate this:

	Grains.
Quantity of sugar employed,	4.750
Potash apparatus, after experiment,	781.13
" " , before experiment,	773.82
Carbonic acid,	7.31
Chloride-of-calcium tube, after experiment,	236.05
" " , before experiment,	223.30
Water,	2.75

7.31 grains carbonic acid = 1.994 grains carbon; and 2.75 grains water = 0.3056 grains hydrogen; or in 100 parts of sugar, carbon, 41.98; hydrogen, 6.43; oxygen by difference, 51.59.

For the methods of determining other elements quantitatively, such as nitrogen, chlorine, sulphur, phosphorus, &c., we must refer to the various works that have been published on organic analysis, amongst which those of Liebig, Fresenius, and Rose deserve special mention.

ORGANIC BASES. The present remarks must be regarded as supplementary to the article ALKALOIDS. They refer (1) to the classification of organic bases and (2) to their formation.

(1) From the fact that nearly all artificial organic bases are (as will be afterwards shewn) actually constructed from ammonia, and that, whether artificially or naturally formed, they exhibit the property of basicity, which is a leading characteristic of ammonia, chemists have been led to refer organic bases generally to the typical body ammonia, and to regard them as being constructed upon or derived from the simple type NH_3 . Berzelius believed that all the alkaloids actually contained ammonia as an ingredient of their composition, a view which is now untenable; and it is to Liebig that we are indebted for the idea that they are derivatives of ammonia, or, in other words, amidogen bases or ammonia in which an equivalent of hydrogen is replaced by an organic radical. The subject has been thoroughly worked out by Dr Hofmann, who originally proposed to classify these bodies under the heads of *amidogen*, *imidogen*, *nitrile*, and *ammonium* bases; but afterwards adopted the terms *primary amines*, *secondary amines*, and *tertiary amines*, in preference to *amidogen*, *imidogen*, and *nitrile* bases—the word *amines* being applied to all organic bases that are derived from ammonia (NH_3). The amines may be (1) *monamines*, (2) *diamines*, (3) *triamines*, (4) *tetramines*, or (5) *pentamines*, according as they be constructed upon a single, double, treble, quadruple, or quintuple atom of NH_3 . We shall confine our illustrations of the meaning

of these terms to the monamines, both because they form the most important group, and because they are much more readily elucidated than the other groups, which are extremely complicated in their composition. *Monamines* are constructed upon the simple type of ammonia, H_3N . In *primary monamines* one of the atoms of hydrogen is replaced by an organic radical, R ; and hence their general formula is RH_2N . Ethyl-amine (C_2H_5) H_2N , or $\text{C}_2\text{H}_5\text{N}$, is an example. In *secondary monamines* two of the atoms of hydrogen are replaced by two atoms of either the same or of different radicals. Hence their general formula is $\text{RR}'\text{HN}$, where R and R' may be the same or different radicals. (C_2H_5) $_2\text{HN}$, or $\text{C}_4\text{H}_{11}\text{N}$, and methyl-ethyl-amine, or diethyl-amine (C_2H_5) $(\text{C}_2\text{H}_5)\text{HN}$, or $\text{C}_4\text{H}_{11}\text{N}$, are examples. In *tertiary monamines* the three atoms of hydrogen are replaced by three atoms of the same or different radicals; their formula therefore is $\text{RR}'\text{R}''\text{N}$, when R , R' , R'' may or may not differ from one another. Trimethyl-amine or (C_2H_5) $_3\text{N}$, or $\text{C}_6\text{H}_{15}\text{N}$, and methyl-ethyl-phenyl-amine or (C_2H_5) $(\text{C}_6\text{H}_5)(\text{C}_6\text{H}_5)\text{N}$, or $\text{C}_9\text{H}_{15}\text{N}$, afford examples of the radicals being all the same and of their being all different. This last example affords a good illustration of the fact, that although the modern nomenclature of organic chemistry includes long and apparently complex words, these words to a great degree represent the composition of the substance they are used to indicate; methyl (C_2H_5), ethyl (C_4H_9), and phenyl (C_6H_5), mainly contributing to form methyl-ethyl-phenyl-amine.

(2) Although all attempts at forming in the laboratory those alkaloids that naturally exist in plants, such as morphia, quinia, and strychnia, have hitherto failed, a large number of organic bases have been prepared by artificial means, such as: *a.* By the destructive distillation of organic bodies containing nitrogen. Thus, in the preparation of coal-gas, four at least of these compounds are obtained—viz., aniline, picoline, leukol (or quinoline), and pyridine. *b.* By the distillation of certain nitrogenous compounds with caustic potash. In this way aniline is obtained from indigo. *c.* By the combination of ammonia with the aldehydes and with certain volatile oils which possess the properties of aldehydes. Thus acetic aldehyde yields dimethyl-amine, and oil of mustard yields thiosinamine. *d.* By the substitution (by the action of strong nitric acid) of one atom of nitrous acid (NO_2) for one atom of hydrogen in certain hydrocarbons. *e.* By the processes of fermentation and putrefaction. Thus wheat flour yields by putrefaction trimethyl-amine, ethyl-amine, and amyl-amine.

ORGANIC COMPOUNDS. It was formerly believed that the compounds to which the term *organic* is applied could only be produced by a vital force acting in a more or less complex animal or vegetable organism. Wöhler's discovery in 1828 of the formation of urea, the chief and most characteristic organic constituent of urine, from its inorganic isomer (see ISOMERISM), cyanate of ammonia, rendered this view altogether untenable, and it is now known that very many substances which are products of animal or vegetable organisms, may be formed artificially in the laboratory. Urea may also be obtained by the action of dry ammonia gas upon phosgene gas, a body formed by the direct union of chlorine and carbonic oxide; and, to give another example, when carbonic oxide is passed over highly heated, moist caustic potash, direct combination takes place, formate of potash being formed, which is identical with that prepared by neutralising caustic potash with formic obtained from ants. Although such cases as that of urea, in which a complex organic product ($\text{C}_2\text{H}_4\text{O}_2\text{N}_2$) is produced by the direct union

of three inorganic substances (and many other cases of the same nature might be adduced), shew that there is no definite line of demarcation between organic and inorganic products, it is useful, as a matter of convenience, to classify chemical compounds according to their natural origin.

The following are the leading characteristics of organic compounds: Those which occur naturally rarely consist of more than four elements—viz., carbon, hydrogen, nitrogen, and oxygen—although a few contain sulphur, and possibly (but this is doubtful) phosphorus. By artificial means, however, organic compounds can be formed containing chlorine, bromine, iodine, selenium, tellurium, and many of the metals. Carbon is universally present both in natural and artificial organic compounds. The number of equivalents entering into the composition of organic compounds is usually higher than in the case of inorganic compounds. There is no organic compound into which less than two equivalents of carbon enter, and both oxygen and sulphur only enter these compounds in double equivalents. Melissic acid, for example (one of the constituents of wax), is represented by $\text{C}_{30}\text{H}_{60}\text{O}_4$; that is to say, each equivalent of the acid is composed of 124 equivalents of the elements entering into its composition; and each equivalent of the solid fat, commonly known as stearine, contains 114 equivalents of carbon, 110 of hydrogen, and 12 of oxygen. No instance is known in which an organic compound has been formed by the direct union of its elements in a free state, as many sulphides, chlorides, and oxides (for example) are formed in inorganic chemistry. Their extreme readiness to decompose under the influence of heat, fermentation, putrefaction, &c., is another characteristic of organic compounds, although some artificially prepared inorganic compounds—as, for example, chloride of nitrogen—are also very unstable.

Organic compounds may be composed of carbon and oxygen, as carbonic oxide, C_2O_2 ; or of carbon and hydrogen, as oil of turpentine, $\text{C}_{10}\text{H}_{16}$; or of carbon and nitrogen, as cyanogen, C_2N_2 ; or of carbon, hydrogen, and oxygen, as grape-sugar, $\text{C}_6\text{H}_{12}\text{O}_{12}$; or of carbon, nitrogen, and oxygen, as anhydrous cyanic acid, $\text{C}_2\text{N}_2\text{O}$; or of carbon, hydrogen, and nitrogen, as nicotine, $\text{C}_{10}\text{H}_{14}\text{N}_2$; or of carbon, hydrogen, and sulphur, as oil of garlic, $\text{C}_6\text{H}_8\text{S}$; or of carbon, hydrogen, nitrogen, and oxygen, as caffeine, $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_4$; or of carbon, hydrogen, nitrogen, and sulphur, as oil of mustard, $\text{C}_4\text{H}_8\text{NS}_2$; or finally, of carbon, hydrogen, nitrogen, oxygen, and sulphur, as taurine, $\text{C}_4\text{H}_8\text{NO}_6\text{S}_2$.

ORGANIC RADICALS. Under the term Organic or Compound Radicals (or Radicles, as some chemists write the word) are included a number of groups of elements, of which carbon is always one, which comport themselves chemically like simple elementary bodies. The careful study of organic compounds led chemists to perceive that many of these contained as a proximate constituent a more or less complex atomic group, which in its combining relations behaves precisely like the elementary substances, and which, like them, may be transferred from one compound to another; and hence the inference was drawn, that all organic compounds were combinations of organic radicals with oxygen, sulphur, hydrogen, or other elements, or of one organic radical with another. In accordance with this view, Liebig defined organic chemistry as *The Chemistry of Organic Radicals*. In order to shew how much the theory of organic radicals serves to elucidate the composition of organic compounds, and to reduce the laws of organic to those of inorganic chemistry, we will point out some of the chemical analogies between the radical *ethyl* (C_2H_5) and the

metal potassium (K), and between the radical cyanogen (C₂N) and the halogen chlorine (Cl). *As* is the symbol for ethyl, *Cy* for cyanogen.

KO = Oxide of potassium.	AsO = Oxide of ethyl or of potash.
KO,HO = Hydrated potash.	AsO,HO = Hydrated oxide of ethyl or alcohol.
KO,SO ₂ = Sulphate of potash.	AsO,SO ₂ = Sulphate of oxide of ethyl.
KCl = Chloride of potassium.	AsCl = Chloride of ethyl.
KS = Sulphide of potassium.	AsS = Sulphide of ethyl.
HCl = Hydrochloric acid.	HCy = Hydrocyanic acid.
KCl = Chloride of potassium.	KCy = Cyanide of potassium.
NH ₄ Cl = Chloride of ammonium.	NH ₄ Cy = Cyanide of ammonium.
HgCl = Chloride of mercury.	HgCy = Cyanide of mercury.

Again, if under certain conditions chloride of ethyl is brought into contact with hydrated potash, the reaction expressed in the following equation occurs:

which shews that the ethyl and the potassium may mutually replace one another in compounds; and the same might be similarly shewn of cyanogen and chlorine.

Comparatively few organic radicals have been obtained in an isolated state; and in most cases the existence of any special radical is only inferred from the fact, that the group of atoms of which it is supposed to be composed can be transferred from one elementary substance to another, and can be made to enter into combination with other organic radicals. The existence of ethyl was thus inferred long before the substance itself was isolated, and the radical benzoyl, C₇H₅O₂ (symbol, Bz), which exists in the oil of bitter almonds, and on which Liebig specially bases his whole theory of organic radicals, has never been isolated. The simplicity obtained by adopting the radical theory in place of using merely empirical formulas, is well shewn in the two contrasted modes of symbolically representing the compounds which are obtained from this oil:

Empirical Formula.	Rational Formula (Bz = C ₇ H ₅ O ₂).
Oil of bitter almonds, C ₁₄ H ₉ O ₂	= BzH, Hydride of benzoyl.
Benzole acid, C ₁₄ H ₉ O ₂ , HO	= BzO,HO, Hydrated oxide of benzoyl.
Chlorine-compound, C ₁₄ H ₉ O ₂ Cl	= BzCl, Chloride of benzoyl.
Sulphur-compound, C ₁₄ H ₉ O ₂ S	= BzS, Sulphide of benzoyl.
Cyanogen-compound, C ₁₈ H ₅ O ₂ N	= BzCy, Cyanide of benzoyl.

The organic radicals are either binary or ternary in their composition. Many of them—as, for example, ethyl—consist of carbon and hydrogen; others, as carbonyl (or carbonic oxide), of carbon and oxygen; others, as cyanogen, of carbon and nitrogen; and others again, like benzoyl, of carbon, hydrogen, and oxygen. Into a few radicals a metallic element enters; these are termed organo-metallic radicals; and cacodyl, which contains arsenic, and is represented by the formula As(C₂H₅)₂, is the best example of this class.

ORGANISTA, the common name of a number of small South American birds, allied to wrens, and remarkable for the sweetness of their song. The Peruvian O. (*Troglodytes leucophrys* of Tschudi) has a modest, cinnamon-brown plumage, with head and neck of dark olive. 'The tender melancholy strains, and the singular clearness of the innumerable modulations, charm the ear of the traveller, who, as if arrested by an invisible power, stops to listen.'

ORGANO-LYRICON, a musical instrument invented by M. de Saint Pern, and consisting of a pianoforte, combined with twelve kinds of wind instruments—bassoon, horns, &c. It has two rows of finger-keys and pedals.

ORGANO-METALLIC BODIES. Under this term are included a large number of chemical compounds in which organic radicals, such as methyl (C₂H₃), ethyl (C₂H₅), &c., are united to metals. If, for instance, in chloride of zinc (ZnCl) we replace the chlorine by ethyl, we produce one of the bodies belonging to this class—viz., zinc-ethyl, Zn(C₂H₅). This substance (which we take as a good example of the class) may be obtained by digesting a mixture of equal volumes of iodide of ethyl and ether with granulated zinc, at a temperature of about 260°, for several hours. Subsequent distillation gives a mixture of zinc-ethyl and ether, from which the former may be obtained pure by rectification, in the form of a colourless, transparent, mobile liquid, which refracts light strongly, has a powerful but not disagreeable odour, and is rather heavier than water, its specific gravity being 1.182 at 64°. In contact with the air, zinc-ethyl takes fire, burning with a green-edged flame and formation of dense white fumes of oxide of zinc. With the exception of cacodyl, As(C₂H₅)₂, these bodies are the creation of the last thirty or forty years, during which period numerous compounds of organic radicals with zinc, cadmium, magnesium, antimony, arsenic, bismuth, mercury, lead, sodium, and potassium have been discovered.

For further information on this subject, see an article by Dr Frankland in the 13th volume of *The Quarterly Journal of the Chemical Society*; also an elaborate article on 'Organo-Metallic Bodies' in Watt's *Dictionary of Chemistry*.

ORGAN-POINT, or PEDAL-POINT, in Music, a bass note sustained through a series of chords, with only the first and last of which it is in harmony. The sustained note may be the dominant or tonic, and sometimes occupies an upper part instead of the bass.

ORGANZINE, a name applied to silk which after having been first wound off from the cocoons into hanks, is then placed on a winding machine, which reels off the hanks on to wooden reels. These are then placed on spindles, and the fibres of each are made to pass through a minute orifice and small brush, which together clean the thread and remove any knots or projections from it, throwing it at the same time into hanks again. Then the threads of two hanks are taken, and again reeled off, this time on to one hank, being twisted together to the left; then two of these doubled reels are taken, and the ends being laid together, are twisted to the right. These operations, consisting of winding, cleaning, throwing, and twice twisting and doubling, constitute organzine silk. See SILK.

ORGEAT, a kind of culinary preparation, which is both used as an agreeable syrup to mix in certain drinks, or medicinally as a mild demulcent. It is prepared by making an emulsion of almonds, which are blanched for the purpose, and beaten into a paste in a mortar, and then rubbed up with barley-water. The proportions are—1 lb. of sweet and 1 oz. of bitter almonds, to a quart of barley-water. To this emulsion are added 2 lbs. of powdered loaf-sugar, and a quarter of a pint of orange-flower water. There are other modes of making it, but this is the simplest and best. It is much used in France under the name of *Sirup d'Orgéat*.

ORGIES (probably from Gr. *erdo*, in the perfect, *eorga*, to sacrifice), or **MYSTERIES**, secret rites or customs connected with the worship of some of the pagan deities; as the secret worship of Ceres (q. v.), and the festival of Bacchus, which was accompanied with mystical customs and drunken revelry. The name is now applied to scenes of drunkenness and debauchery.

ORGUES are thick, long, wooden beams, pointed and shod with iron, hung vertically by separate ropes in the gateway of, and over the entrance to a fortified place. They answer the purpose of a portcullis or door, and are dropped into position by cutting the ropes from which they hang. Their descent is inevitable, in which they possess an advantage over the portcullis, which may be held up by the enemy or blown in by petards, whereas petards have little effect on orgues, for if one beam be destroyed, another can be dropped to fill up the gap.

O'RIEL COLLEGE. In 1324, Adam de Brom, almoner of Edward II., procured from the sovereign a charter of incorporation for a college, under the name of St Mary's House, in Oxford. The origin of the name 'Oriol College' is uncertain. It consisted originally of a provost and 10 fellows. The number of fellows was by subsequent benefactions raised to 18, and several exhibitions and scholarships were also founded at various times. By the commissioners under 17 and 18 Vict. c. 81, all the fellowships are thrown open, but two are in the meantime suspended for the purpose of increasing the number and value of the scholarships, and of augmenting the salary of the professor of modern history. By the same authority the scholars are placed on the foundation of the college, a position they did not before enjoy; the scholarships are made ten in number, tenable for five years, of value £80 per annum, with rooms free. This college was one of the first to throw open such of its fellowships as it could to competition, and hence the fellows of Oriol have long been among the most distinguished men in the university. For several years back, however, its undergraduates have done little in the schools. The fellows divide upwards of £200 a year, in addition to allowances; and the income of the provostship, to which is annexed a living in Essex and a canonry in Rochester Cathedral, is estimated at £2000 a year. There are thirteen benefices in the gift of this college.

ORIEL WINDOW, a projecting window having more sides than one, usually three, and commonly divided into bays by mullions. It is one of the most picturesque features in medieval and Elizabethan domestic architecture, and adds much to the convenience of the interior. The word oriel (Med. Lat. *oriolum*, probably dim. from *os*, *oris*, as if a small opening or recess) formerly meant a chamber or apartment, and a window is so called which makes a small apartment, as it were, off a large room. Oriels are also called Bay or Bow Windows (q. v.).

ORIENTATION. As Christians from an early period turned their faces eastward when praying, so Christian churches for the most part were placed east and west, in order that the worshippers, as they looked towards the altar, might also look towards the east. Modern observation, however, has found that few churches stand exactly east and west, the great majority inclining a little either to the north or to the south. Thus, of three ancient churches in Edinburgh, it was ascertained that one (St Margaret's Chapel in the Castle) pointed E.S.E.; another (St Giles's Cathedral), E.-by-S.½S.; a third (Trinity College Church, now destroyed), E.½S.

This deviation from the true east has received, among English ecclesiologists, the name of 'Orientation.' Its origin or cause has not been satisfactorily explained. Some have supposed that the church was turned not to the true east, but to the point at which the sun rose on the morning of the feast of the patron saint. But, unfortunately for this theory, neighbouring churches, dedicated in honour of the same saint, have different orientations. Thus, All Saints' at West Beckham, in Norfolk, points due east; while All Saints' at Thwaite, also in Norfolk, is 8° to the north of east. There are instances, too, in which different parts of the same church have different orientations; that is to say, the chancel and the nave have not been built in exactly the same line. This is the case in York Minster and in Lichfield Cathedral. Another theory is, that orientation 'mystically represents the bowing of our Saviour's head in death, which Catholic tradition asserts to have been to the right [or north] side.' But this theory is gainsaid by the fact, that the orientation is as often to the south as to the north. Until some better explanation is offered, it may, perhaps, be allowed to hold, that orientation has had no graver origin than carelessness, ignorance, or indifference.

ORIFLAMME, or **AURIFLAMME** (Lat. *auri flamma*, flame of gold), a banner which originally belonged to the Abbey of St Denis, and was borne by the Counts of Vexin, patrons of that church, but which, after the county of Vexin fell into the hands of the French crown, became the principal banner of the kingdom. It was charged with a saltire wavy or, with rays issuing from the centre crossways. In later times the oriflamme became the insignia of the French infantry. The name seems also to have been given to other flags; according to Sir N. H. Nicolas, the oriflamme borne at Agincourt was an oblong red flag split into five parts.

ORIGENES (ORIGEN), called *Adamantinos* or *Chalchentexos*—both epithets expressive of his firmness of purpose and iron assiduity—one of the most eminent of the early Christian writers, 'the father of biblical criticism and exegesis in Christendom,' was born 185 A. D., at Alexandria, where his father, Leonidas, seems to have held some superior office in the church. O. received a most liberal education. While, on the one hand, he was initiated at an early age into Hellenic science and art, the teachings of Christianity were instilled into his mind by men like Pantænus and Clemens of Alexandria. During the persecutions against the Christians, instituted by Sept. Severus, his father died the death of a martyr, and O., then 17 years of age, would have shared it of his own free will, had not his mother, left unsupported with six children, prevented him. After a short time his zeal and erudition procured for him the office of catechist in the Alexandrian church; but no salary being affixed to it, he was fain to dispose of his much-loved collection of classical authors for a daily stipend of four oboli (2d.) for several years. His wants were extremely limited, and his asceticism led him even to self-mutilation (in accordance with the view he took of Matt. xix. 12): an act for which he afterwards expressed the deepest sorrow, and which became a dangerous weapon in the hands of his antagonists. Not a few of his hearers being masters of Greek (Neoplatonic) philosophy, O., in order to ward off more successfully their attacks upon his doctrines, and to combat them on their own ground, applied himself particularly to this science, and Ammonius Saccas himself is said to have been his teacher. From this

period also may be dated O.'s transition from unconscious to conscious belief. He examined henceforth, with as little prejudice as possible, all the different systems of human speculations that came under his notice during the many journeys he undertook, proceeding on the principle 'that we are not, under the pretence of piety, to pin our faith on that which is held by the multitude, and which therefore alone seems to stand on high authority, but on that which results through examination and logical conclusions from established and admitted truths.' This liberality of his mind and doctrines could not fail, on the one hand, to bring about many conversions to the faith, as he taught it, both among 'pagans' and 'heretics,' the latter chiefly of the Gnostic sects; and on the other hand, to raise an outcry among less liberal professors and teachers of the faith, who had not been so successful in their labours. What gave the greatest offence in his teachings was his way of explaining, after the manner of the Midrash, known to him through the Jewish masters (from whom, at an advanced age, he had also learned Hebrew), allegorically and symbolically that which in the Scripture warred with the common human understanding, or seemed repugnant in manner or matter. Furthermore, while upholding all the ethical portions of the Bible, he rejected a great deal of its supposed historical and legal contents for all purposes, save, perhaps, as starting-points for homiletics. 'What edification,' he says, 'could we find in literally interpreting the story of Abraham's first telling Abimelech a lie, and then, with Sarah's consent, handing her over to him and prostituting her?' As to the discrepancies in the different gospels respecting the life of Christ, he says: 'One of two only is possible. Either these things are true in a *spiritual* sense only, or as long as the discrepancies are not satisfactorily explained away, we cannot believe in the gospels being dictated by the Holy Ghost, and redacted under the influence of his inspiration.'

In 211 he went to Rome, but soon afterwards, at the wish of Bishop Demetrius, he returned to Alexandria, which, however, he was obliged to leave precipitately, and to seek refuge from certain popular tumults in Palestine. Here the bishops received him with great honours, and desired him to institute public lectures, in which they themselves became hearers. Recalled again by the Alexandrian bishop, he was sent to Achaia to combat certain heresies that had broken out there. The wrath that had silently been gathering against him found its first vent when, in 228, the bishops assembled in Caesarea in Palestine consecrated him presbyter. The Bishop of Alexandria took umbrage at this outrage, as he called it, on his authority. Two councils were convoked, and in 232, O. was deprived of his priestly office, and excommunicated, the principal heresy charged against him being his denial of eternal punishment. Yet the churches of the East remained faithful to him. Palestine, Arabia, Phoenicia, and Achaia remained in constant communication with him; and men like Gregory Thaumaturgus (q. v.), Athenodorus, and others remained or became his faithful disciples ever after, while the Bishop of Caesarea allowed him openly to expound the Scripture in his church. The persecutions under Maximinus again forced him to seek refuge for two years in Cappadocia. Returning under Gordianus, he resumed his labours and journeys, until, when Decius ascended the throne, he was seized, imprisoned, and tortured for his faith. He did not survive his sufferings long, but died, in 254, at Tyre, where his tomb, near the high-altar of the cathedral, was shewn for many centuries, until it was destroyed during the Crusades.

The number of his works is stated by Epiphanius and Rufinus to have exceeded 6000, and although this is probably only meant as an exaggerated round number, yet the amount of writings that issued from his always busy brain and hands cannot but have been enormous. Seven secretaries and seven copyists, aided by an uncertain number of young girls, are by Eusebius reported to have been always at work for him. The great bulk of his works is lost; but among those that have survived, the most important by far are his two editions of the Old Testament, called respectively *Tetrapla* (fourfold) and *Hexapla* (sixfold). See *HEXAPLA*. The labour bestowed upon this work must have been immense, and no less than twenty-eight years is O. supposed to have been engaged upon it. On its importance for biblical criticism it is needless to enlarge here. Fragments only have come down to us, the original having been lost during the siege and capture of Caesarea by the Arabs; and the Greek as well as the Roman clergy having almost laid an interdict upon the copying of any of O.'s much suspected writings. Montfaucon has collected and edited these fragments (*Hexaplorum Origenis quae supersunt*, 2 vols. fol. Paris, 1714), which were re-edited by C. F. Bahrdt (1769—1770). Of his other partly extant, partly lost works, the chief are his books 'On the Resurrection,' 'On Martyrdom,' 'Eight Books against Celsus,' 'On Prayer,' besides Epistles, &c. He further revised and enlarged Philo's Lexicon of Hebrew Names (*Hebraicorum Nominum S. Scripturae et Mensurarum Interpretatio*), whence it has often, together with many other spurious works, been ascribed to him exclusively. Little also has survived of his many exegetical writings, commentaries, brief notes, and homilies on both Testaments. The best editions of his collected works are by De la Rue (Paris, 1733; 2d ed. 1856); by Oberthür (1785, 15 vols.); and by Lommatsch (Berlin, 1831—1848). See works on O. by Thomasius (1837) and Redepenning (1846); also Herzog.

ORIGINAL SIN. According to this theological tenet, when stated in its extremest form, men come into the world with the reason and will utterly corrupt. This corruption originated in the fall of Adam, and has been inherited equally by all his posterity, so that the natural man is not only incapable of knowing and loving God and goodness, but is inclined to condemn God and pursue evil; on which account the anger of God has subjected him to temporal death, and destined him to everlasting punishment in hell. The doctrine is founded on the account of the fall given in Genesis, and on some passages in Paul's Epistle to the Galatians, and in that to the Romans; which passages, however, are held by others to contain no such doctrine; and indeed nearly every point in the history of the doctrine is the subject of as much controversy as the details of the doctrine itself. The early church, it is maintained by one school, was unacquainted with it; and the most orthodox admit that the doctrine had not at that time been fully developed. The Christian fathers, Justin Martyr, Clemens Alexandrinus, Irenaeus, and others, ascribe to the natural man a certain ability to know God and choose the good, they are said to reject distinctly all propagation of sin and guilt, and even to refer human mortality not to Adam's sin, but solely to the constitution of the body. Origen, on the other hand, in opposition to the Gnostics and Manichees, who grounded the sinfulness of men on the connection of the soul with a material body, asserted that the sinfulness was in existence at birth, but ascribed the development of actual sins and their consequences not

to propagation, but to the moral operation of precept and example. He accordingly found the cause of sin to be in the freedom of the will, the abuse of which he explained partly by the operation of evil powers, partly by the predominance of the sensuous part of man's nature over the rational mind. The orthodox teachers of the Greek Church, again, held that Adam, by the fall, rendered himself and all his posterity mortal, but, according to the less rigid schools, they looked for the origin of sin in the freedom of the will acted upon by the flesh, and by demoniacal influences, and ascribed to man the power of resisting every evil if he chose. These views, it is alleged, continued to be held, in substance, by the Christian teachers in the east, and were fully developed by Chrysostom; but Catholic writers maintain that in all this Chrysostom and the other Greek Fathers are speaking not of the natural powers of the will, but of the will as assisted by divine grace.

The doctrine took another shape in the Latin Church. Tertullian, following up his dogma of Traducianism, according to which the child derives not only its body but its soul from its parents, maintained that sinfulness had been propagated, along with mortality, from Adam to all mankind; he thus defended an *originalis vitium*, without conceiving it as actual sin and denying all capacity for good in man. This view was followed by Cyprian, Ambrose, and even by Augustine in his earlier writings. It was only during his controversy with Pelagius and Celestius that Augustine came to develop the doctrine of original sin into the full form given above. His great influence in the western churches procured the condemnation of his opponents, the Pelagians (q. v.), as heretics at the Councils of Carthage (412, 416, 418), although the Councils of Jerusalem and Diospolis (415) decided in their favour. Building upon the foundation of Traducianism, Augustine laid down that every natural man is in the power of the devil, and upheld the justice of this as a punishment for the share which the individual had in Adam's transgression; for as all men existed in the loins of Adam, all sinned with him. Pelagius, on the other hand, who rejected the Traducian theory, denied that sin is propagated physically, or that the fall of Adam has exercised any prejudicial influence on the moral constitution of his posterity; and maintained that all men are born in a state of innocence, possess the power of freewill, and may therefore live without sin. He and his followers objected to Augustine, that his doctrine was in direct contradiction to clear passages of Scripture, and that it made God the originator of evil and an unrighteous judge.

Great as was the respect for Augustine, the harshness of his doctrine was too shocking to the natural sentiments to meet with lasting acceptance. In the eastern church it never gained a footing, and even in the west it met with opposition. In Gaul, John Cassian, Faustus, Arnobius, and others, took up a view midway between the views of Augustine and Pelagius, from which they were called Semipelagians. They attributed to man a capacity for good which makes it possible for him, not indeed to merit the favour of God, but to make himself capable of receiving it; and maintained that it is only a certain inborn weakness that men inherit from the first pair. The Semipelagian doctrine found acceptance especially among the monks (in particular among the Franciscans), continued to prevail during the middle ages, and among the scholastics found partisans in the Scotists. Augustine's views also found advocates among the scholastic philosophers, who, however, added to it many limitations and explanations. Regarding the way

in which original sin is propagated, many held by the Traducian theory, while others conceived it to be a sort of infection of the soul by the defiled body, or an imputation of guilt to all partakers of the human nature. Petrus Lombardus adhered to Augustine. Anselm of Canterbury conceived original sin to be a want of requisite righteousness, and thought that this want was imputed to all the posterity of Adam, although not in the same degree as if they had themselves sinned. Anselm's view was adopted by Duns Scotus, while Bonaventura and Thomas Aquinas sought to combine the opinions of Anselm and Augustine. Anselm had thought that his theory afforded a better explanation of the sinless birth of Christ; and about the 12th c. it began to be maintained that Mary also was conceived without sin.

The reformers of the 16th c. everywhere made original sin a leading doctrine, and thus were enabled to combat effectively the Roman Catholic doctrine of the merit of works; while the Catholic Church, in the fifth session of the Council of Trent, stamped what the Calvinist school would call Semipelagianism as the orthodox doctrine. The reformed churches agreed with the Lutheran on the point of original sin. In this they followed Calvin rather than Zwingli, who looked upon it as an evil or disease, and as becoming sin only when a commandment is transgressed. The Arminians and Socinians, on the other hand, denied the doctrine of hereditary sin in the ecclesiastical sense. The Mennonites spoke of a loss of the divine image in consequence of the fall of Adam, but still asserted the freewill of man. The Quakers rejected the name of original sin altogether; they held that there is a germ of sin in man, from which imputable sin springs, and that, however corrupt, he has still the susceptibility of being awakened to the inward light. The whole Protestant Church held, besides, that Jesus alone was free from sin, both original and actual. The Roman Catholic Church ascribed this attribute also to Mary, though no public and distinct declaration on the point was given by the Council of Trent. See IMMACULATE CONCEPTION.

The harshness of the Augustinian dogma led, at the time of the Reformation, to keen controversies; Erasmus disputed the point with Luther, and would only admit a weakness of the freewill arising from original sin, and by no means a complete annihilation of it. From that time the doctrine in Germany continued to be variously attacked and defended. It has been discussed by the schools of philosophy. Kant shewed the moral significance of the dogma, and made out original sin to be a propensity to evil inherent in man. The Schelling-Hegel school, again, explained it as the finite nature with which the individual is born. In recent times, the theologians of the old Lutheran and strictly orthodox tendencies, such as Olshausen, Tholuck, Hengstenberg, and others, have come forward as adherents and defenders of the Augustinian doctrine; while the more liberal theologians modify it in various ways, not admitting any moral inborn corruption arising from the fall, but only a weakness in man's nature for the knowledge and performance of good. How far, and with what differences, the extreme Augustinian view is held by the churches of England and Scotland, will be seen from the following extracts from the *Thirty-nine Articles* and the *Westminster Confession of Faith*.

From Art. ix. of the *Thirty-nine Articles*: 'Original sin standeth not in the following of Adam (as the Pelagians do vainly talk); but it is the fault and corruption of the nature of every man, that naturally is engendered of the offspring of

Adam, whereby man is very far gone from original righteousness, and is of his own nature inclined to evil, so that the flesh lusteth always contrary to the spirit; and therefore in every person born into the world, it deserveth God's wrath and damnation.'

From chap. vi. of the *Westminster Confession*: 'By this sin' (i.e., the eating of the forbidden fruit), 'they' (i.e., our first parents) 'fell from their original righteousness and communion with God, and so became dead in sin, and wholly defiled in all the faculties and parts of soul and body. They being the root of all mankind, the guilt of this sin was imputed, and the same death in sin and corrupted nature conveyed to all their posterity, descending from them by ordinary generation. From this original corruption, whereby we are utterly indisposed, disabled, and made opposite to all good, and wholly inclined to all evil, do proceed all actual transgressions.'

ORIHUELA, an ancient town of Spain in the modern province of Alicante, and 36 miles south-west of the city of that name, stands on the banks of the Segura, in a plain remarkable alike for its beauty and its fertility. It is long and straggling, while its palm-trees, square towers, and domes give it an oriental appearance. It contains a cathedral, numerous churches and convents, barracks, &c. The manufactures are linen goods and hats, and many corn and oil mills and tanneries are in operation. Olive oil is very extensively made. The vegetation here is gigantic; the oleanders are actual trees. O. has been possessed by Carthaginians, Romans, Moors, and Spaniards in turn. Pop. 24,000.

ORILLON, in Fortification, and especially in the earlier systems, is a semicircular projection at the shoulder of a bastion, intended to cover from

Orillon :

a, a, orillons; b, b, retired flanks (the dotted lines shew the original bastion).

the observation of the enemy the guns and defenders on the flank, which, with such a construction, is somewhat retired or thrown back. The flank thus protected is held by many distinguished engineers to be most valuable in the defence

of the ditch, in clearing it from an attacking party, or from hostile miners. The retired flank is sometimes straight, at others curved, as in the figure. The orillon is as old as the bastion, and is found in the works of Pagan and Speckle.

ORINO'CO, a great river of South America, flows through Guiana and Venezuela, and reaches the Atlantic Ocean south of Trinidad, in lat. 8° 40' N. The country in which it takes its rise is inhabited by an aboriginal race called the Guaiacas, who have hitherto prevented all access by foreigners to its sources; but it is known to rise in the Sierra Parime, one of the chief mountain chains of Guiana, near lat. 3° 40' N., long. 64° 30' W. It has been explored by Humboldt to the village of Esmeraldas (lat. 3° 8' N., long. 66° 8' W.), and by Schomburgk to within 30 miles of its source. After flowing west-south-west 20 miles past Esmeraldas the river bifurcates, and the southern branch, the Cassiquari (q. v.), flowing south-west, joins the Rio Negro, an affluent of the Amazon. From this point the O. flows north-west to its junction with the Guaviare, then north-north-east to its junction with the Apure, after which it flows in an eastward direction to its mouth. Length of course, 1960 miles. The head of uninterrupted navigation is at the confluence

of the O. with the Apure, 777 miles from the mouth of the river. Above this point the course of the river is interrupted by 'raudals' or cataracts, of which those of Maypures and Atures are the most celebrated. Its principal affluents from the left are the Guaviare, the Vichada, the Meta, and the Apure; from the right, the Ventuare, Caura, and Caroni. The O., which is joined by 426 rivers, and upwards of 2000 streams, drains an area (usually stated at 250,000 square miles) which, according to Wappän's *Republiken von Süd-Amerika*, may be estimated at 650,000 square miles. It begins to form its delta 130 miles from its mouth, by throwing off a branch which flows northward into the Atlantic. Several of the mouths are navigable, and the main stream, the Boca de Navios, is divided by a line of islands into two channels, each two miles in width. Bolivar, a town upwards of 250 miles from the mouth of the river, marks the head of tide-water, and here the river is 4 miles wide and 390 feet deep. Below the junction of the Apure the character of the scenery seems to be uniform—forests on the right bank, and llanos on the left.

ORIOLE (*Oriolus*), a genus of birds of the Thrush family (*Merulidae* or *Turdidae*), having an elongated conical beak, broad at the base; the upper mandible ridged above, and notched at the point; wings of moderate size, the first feather very short, the third the longest; the tail of moderate length, and rounded; the tarsus not longer than the middle toe; the outer toe joined at its base to the middle toe; claws strong and curved. The species are numerous, all natives of the Old World, and chiefly of the warmer parts of it; the adult males generally of much brighter plumage than the females and young males, the prevalent colour yellow. Only one species is found in Europe, the **GOLDEN O.** (*O. galbula*), pretty common in Italy and some other parts of Europe, but a rare summer visitant of England, and never seen in Scotland, although it occasionally breeds in the south of Sweden.—The name O. is still very commonly given to the Baltimore Bird (q. v.) and other American birds of the Starling family, the chief resemblance of which to the true orioles is in colour.

ORION, in Greek Mythology, was a gigantic hunter, and reputed the handsomest man in the world. His parentage is differently given. According to the commonly received myth, he was the son of Hyrieus of Hyria, in Boeotia, and was called in his own country Kandaon. Another account makes him a son of Poseidon and Euryale, while some state that he was *Autochthonos*, or 'earth-born.' So immense was his size, that when he waded through the deepest seas he was still a head and shoulders above the water; and when he walked on dry land, his stature reached the clouds. Once on a time he came to Chios, in the Ægean Sea, where he fell in love with Eero or Merope, daughter of Enopion. He cleared the isle of wild beasts, and brought their skins as presents to his sweetheart; but her father always put off their marriage; whereupon O., one day giving way to passion (when under the influence of wine), sought to take the maiden by force. Enopion now called upon Dionysus (Bacchus) for help, who put out the eyes of the inebriate lover. O., however, recovered his sight in Lemnos, by following the advice of an oracle, and returned to Chios to take vengeance on Enopion. Not finding him, he went to Crete, where he spent the rest of his life hunting in company with Artemis (Diana). The cause and manner of his death are differently related. Artemis,

say some, slew him with an arrow, because Eos, inflamed by his beauty, had carried him off to Ortygia, and thereby offended the gods. Others aver that Artemis, virgin-goddess though she was, cherished an affection for him, that made her brother Apollo fiercely indignant. One day, pointing out to her at sea a black object floating in the water, he told her that he did not believe she could hit it. Artemis, not recognising her favourite, drew her bow, and pierced him through the head; a third myth makes him find his death from the sting of a scorpion. Asklepios (*Æsculapius*) wished to restore him to life, but was slain by a bolt of Zeus. After his death, O. was placed with his bound among the stars, where, to this day, the most splendid constellation in the heavens bears his name.

ORISSA, an ancient kingdom of Hindustan, the authentic history of which goes back to 473 A.D., extended from Bengal—a part of which it included—on the N., to the banks of the Godavari on the S., and from the coast on the E. to the river Gondwana on the W. From its remains of sculptures, inscriptions, &c., we may infer that its early civilisation was high. The temple of the sun at Kanārek—erected about the 12th c.—exhibits carvings representing the planets, sculptured figures of animals, &c., which shew that at that date the plastic and mechanical arts were in a more advanced state in O. than they were in England. It maintained its position as an independent monarchy till 1558, when, its royal line having become extinct, it became an outlying province of the empire of the Great Mogul. On the breaking up of this empire, the more valuable portions of O. were seized by the Nizam of Hyderabad. The French, who had taken possession of a part of the country long known as the Northern Circars, attempted to drive the English (who had also formed commercial settlements on the coast), out of India. The result of the contest for supremacy in India between the French and English is well known. The Mahrattas, who had seized a portion of O. in 1740, were forced to surrender it to the English in 1803. The soldiers of the East India Company were marched into O. at the commencement of the present century, and an engagement was subsequently entered into between the Company and the native chiefs and princes, by which the former bound themselves to perform certain services for the country (as maintaining the river-banks in good repair), while the latter engaged to pay a yearly tribute. Of the many principalities into which O. was divided, a large number got into arrears with the government, and the result was that numbers of the estates were sold, and the government, as a rule, became the purchaser. Much of the territory originally forming a portion of this kingdom thus fell into the hands of the British. The ancient O., which existed as an independent monarchy for four centuries, and flourished as a principality of the Mogul empire after 1558, is now hardly to be recognised in the British commissioner-ship of O., with an area of 23,901 sq. m., and a pop. of (1872) 4,317,999. This country was decimated by famine in 1868-69; and careful surveys of its coast were made in 1870. O. is traversed by a branch of the Eastern Ghauts running parallel with the coast. The hill-districts, which nowhere present an elevation of more than 3000 feet, are inhabited by the Gonds, the Koles, the Sourahs, and the Khonds. The Khonds occupied an area extending from north of the Mahanaddi, south to the banks of the Godavari. Their mountain-haunts are admirably suited for defence, as the districts which they inhabit are almost inaccessible; and although they do not yet appear to have adopted firearms, they manage their battle-

axes and bows and arrows with an adroitness and courage that make them formidable enemies. The Khonds are a totally distinct race from the inhabitants of the plains, and there is but little resemblance between them and the other hill-tribes, the Gonds and Sourahs. The chief peculiarities of the Khonds are, that their language, which is quite distinct from those of the neighbouring tribes, is not in the least understood by the inhabitants of the plains; and that human sacrifice formed, till within the last few years, one of the distinguishing features of their religion. They do not barter or traffic, and all commercial transactions are managed for the Khonds by the Panus, Doms, &c., regarded by their employers as inferior races. There are, however, no caste prejudices among the Khonds such as generally prevail throughout the plains of India. Agriculture and war are the only employments. The revolting custom of human sacrifice prevailed among the Khonds from the earliest times, although it was not till 1836 that the attention of the government was specially called to the subject, at the conclusion of an insurrection, in the course of which British officers had been brought into contact with the Hill tribes. The Khond victims, called Meriah, were always bought with a price, sometimes from families of their own tribes who had fallen into poverty, but generally kidnapped from the plains by miscreants of the Panu race. The Meriah victims were of both sexes, and of every age; though adults were held in the highest esteem, because, being the most costly, they were supposed to be more acceptable to the deity. The object of the sacrifice was to propitiate the earth-god; and abundant crops, security from calamity, and general prosperity were supposed to be insured to any one who had cut off a portion of the flesh of the human victim, and buried it in his farm. The consummation of the Meriah sacrifice was often attended with circumstances of the most revolting and disgusting cruelty. In some cases the event was preceded by a month's feasting, intoxication, and dancing round the Meriah. On the day before the sacrifice, the priest thus addressed the victim: 'We have bought you with a price, and did not seize you; now we sacrifice you according to custom, and no sin rests with us.' On the following day the victim was made senseless from intoxication, and then suffocated; after which the officiating priest cut a portion of the flesh from the body, and buried it as an offering to the earth-god. The people, following his example, hewed the flesh from the bones, and carried the bloody trophy to their distant villages, where it was buried. In many cases the victim was not intoxicated before sacrifice; but the joints of his arms and legs were broken with a hatchet, in order to prevent the possibility of resistance. In 1837, General (then Captain) Campbell was appointed assistant-collector in Ganjam, the adjoining district in the plains, and with varied success devoted much of his time to endeavouring to suppress the rite. He was succeeded in 1841 by Major (then Lieutenant) Macpherson, C.B. Encouraged by the success of his labours, the government in 1845 established, under Macpherson, a separate agency for the suppression of Meriah sacrifices in the Hill tracts of O., in which he was succeeded, in 1847, by Major-general Campbell, who carried on, with undiminished success, the good work commenced by Macpherson, pushing his inquiries and exerting his authority among tribes unvisited by his predecessor; and reports have been sent in from all parts of the country, stating that for several years hardly any Meriah sacrifices have taken place in the great Hill tract of Orissa. In the year 1852

ORISTANO—ORKNEY ISLANDS.

—1853, all victims retained for sacrifice were demanded, and in only one instance had the demand to be followed up by force. The practice of female infanticide has now also become almost wholly suppressed. The irrigation of a large portion of O. is provided for by an extensive and costly system of canals taken over by the government in 1868.

IX., XI., XV., and XX.*; *Kaye's History of the Administration of the E. I. Coy., 1853*; *Memoir: Administration of India during Last Thirty Years, 1858*; *Indian Records—History of the Rise and Progress of the Operations for the Suppression of Human Sacrifice and Female Infanticide in the Hill Tracts of Orissa (1854)*; and *Orissa, by W. W. Hunter, Director-general of the Statistical Survey of India (1872)*.

ORISTANO, a town, and inferior river port on the west coast of Sardinia, 56 miles north-west of Cagliari. It stands in a fruitful, well-cultivated plain, about a mile from the left bank of the Tirso or Oristano, and 3 miles from its mouth in the Gulf of Oristano, which is about 10 miles in length, with a breadth of 5 miles. It is surrounded by ancient walls flanked with towers; contains a cathedral with a great clock tower, the most conspicuous object in the town; an archbishop's palace, college, and several churches and convents. It carries on manufactures of ironware, cutlery, and agricultural implements, and a number of its inhabitants are engaged in the tunny fishery on the coast. Corn, salt fish, and the wine of Vernaccia are exported. In winter the town is busy and lively; but in summer it is unhealthy, and during that season all who can afford to do so, leave it. Pop. 2500.

ORIZABA, a town of Mexico, in the state of Vera Cruz, 70 miles west-south-west of the town of that name, and 25 miles south of the volcano of Orizaba. The vicinity is unusually fertile, and is covered with forests. The town contains numerous churches, a high school, and an extensive cotton spinning-factory. Coarse cloths and tobacco are largely manufactured, and there is much general industry. Pop. 15,000.

ORKNEY ISLANDS, which, with Shetland, form one county, separated from Caithness by the Pentland Firth (q. v.), lie between 58° 41' 24" and 59° 23' 2" N. lat., and between 2° 22' 2" and 3° 25' 10" W. long.; and are 73 in number at low-water, of which 28, besides Pomona, or the Mainland, are inhabited. The area of the O. I. is 610 square miles, or 390,147 imperial acres. The surface is very irregular, and the land is indented by numerous arms of the sea. The highest hill is the Ward of Hoy, 1555 feet. The rocks are of the old red sandstone formation, except a small granitic district near Stromness. Previous to the middle of last century, the agriculture of Orkney was, in more than an ordinary degree for the time, in a primitive state. There was little communication then with the mainland, and improvements were slowly adopted. The spinning-wheel, for instance, was not introduced there for half a century after it was in use elsewhere. Until towards the end of last century, little advance seems to have been made in the management of the land, the inhabitants deeming it more important and profitable to direct their attention to the manufacture of kelp. The people used to suffer periodically from bad seasons and violent storms, when less help could be afforded to them from without. In 1778, a great hurricane of four hours' duration drove the

sea-spray over the islands. The grain crop was in consequence *sea-gusted*, and rendered almost worthless, and there required to be imported 18,000 bolls of meal and bere, besides other articles, costing £15,000, or nearly twice the gross rental of the county. Orkney was formerly divided into 32 parishes, having 8 parish ministers. It now contains 22 parishes, forming 3 presbyteries and 1 synod. There are also about 30 congregations belonging to the Free and United Presbyterian Churches, besides 3 Independent, and one or two others.

The temperature of Orkney is comparatively mild, considering its northern latitude. This arises partly from its being surrounded by the sea, but chiefly from the neighbourhood of the Gulf Stream to the western shores. For the 13 years ending 1869, the mean annual temperature was 46°; the mean temperature of January and February, the coldest months, 39°; and that of July, 55°. The annual rainfall varies from about 28 inches on the east side of the Isles to 37 inches on the west.

The carrying-trade and merchandise of Orkney have greatly increased of late years. The exports rose from £49,308 in 1848 to £181,483 in 1861. The value of exports, in 1871, exceeded £250,000. The exports are chiefly of fish and agricultural produce, of which cattle are the principal. The number of eggs exported in 1880 was over 11,000,000, of the value of above £32,000.

The total acreage in 1881 under all kinds of crops, bare fallow, and grass, was 108,795; barley and bere, 5910 acres; oats, 32,373 acres; turnips, 13,952 acres; potatoes, 3137 acres. The number of horses in 1881 was 6181; cattle, 26,103; sheep, 29,064; swine, 3769. The number of occupants of land was 3147.

The valued rent of the O. I. in 1653 was £57,149 Scots, or £4763 sterling. The valuation (exclusive of the burgh of Kirkwall) in 1879–80 was £68,061. Population of the O. I. in 1871, 31,274; in 1881, 32,037. Parliamentary constituency in 1879–80, 1333, returning one member conjointly with Shetland. The chief towns are Kirkwall (q. v.), the capital (situated in Pomona), and Stromness, in which there are 3 distilleries, producing upwards of 20,000 gallons of whisky annually; but Kirkwall is the only royal burgh in the shire.

The Orkneys, under the name *Orcades* [whence the modern adjective, *Orcadian*], are mentioned by the ancient geographers, Pliny, Ptolemy, Mela, and by other classical writers, but of their inhabitants we know almost nothing till the dawn of the Middle Ages. They were most probably of the same stock as the British Celts. From an early period, however, the Norsemen resorted to these islands, as a convenient spot from which to make a descent on the Scotch and English coasts. In 876, Harald Haarfager conquered both them and the Hebrides. During the greater part of the 10th c., they were ruled by independent Scandinavian jarls (earls), but in 1098 they became formally subject to the Norwegian crown. Thus they remained till 1468, when they were given to James III. of Scotland as a security for the dowry of his wife, Margaret of Denmark. The islands were never redeemed from this pledge; and in 1590, on the marriage of James I. with the Danish Princess Anne, Denmark formally resigned all pretensions to the sovereignty of the Orkneys. During their long connection, however, with Norway and Denmark, all traces of the primitive population disappeared. The present proprietors of land are chiefly of Scotch descent; and the inhabitants generally are a mixed race of Scandinavian and Scotch descent.

ORLE, in Heraldry, one of the charges known under the name of sub-ordinaries, said to be the diminutive of a Bordure (q. v.), but differing from it in being detached from the sides of the shield. It may be the sole charge in a shield. Or, an orle gules was the coat borne by John Baliol. An orle

Orle.

of heraldic charges of any kind denotes a certain number (generally eight) of these charges placed in orle, as in the coat of the old Scottish family of Gladstones of that Ilk; argent, a savage's head couped, distilling drops of blood proper, thereon a bonnet composed of bay and holly leaves all proper, within an orle of eight martlets sable.

ORLEANS, an important commercial town of France, capital of the department of Loiret, and formerly capital of the old province of Orleannais, which now forms the greater part of the departments of Loiret, Eure-et-Loir, and Loir-et-Cher, is situated on the right bank of the Loire, here crossed by a bridge of 9 arches, and is 75½ miles south-south-west of Paris by railway. Close to the city is the Forest of O., one of the largest in the country, consisting of 94,000 acres, planted with oak and other valuable trees. O. stands on the verge of a magnificent plain sloping toward the Loire, and watered by the Loire and Loiret, and is surrounded on the land-side by a wall and dry ditches, on either side of which there are pleasantly shaded boulevards. Around it are eight prosperous and populous suburbs. Among its principal buildings are the cathedral, with two lofty and elegant towers, one of the finest Gothic edifices in the country; the tower; bishop's residence; the houses of Joan of Arc, of Agnes Sorrel, of Diane de Poitiers, of François I., of Pothier; the churches and hospitals, which are numerous; the *musée*, theatre, &c. The town contains three statues of Joan of Arc, of which the equestrian one was inaugurated in 1855. The situation of the town has many commercial advantages, arising from its position on a navigable river, on lines of railway which connect it with Paris and the great trading towns in the south of France, and on the canal which connects the Loire with the Seine. Hosiery, cotton and linen goods, refined sugar, vinegar, bleached wax, leather, &c., are manufactured; and the trade is chiefly in stockings, sheepskins, wine, brandy, corn, and sugar. Pop. (1880) 57,314.

O., originally called *Genabum*, afterwards *Aurelian* (probably from the Emperor Aurelian), of which the modern name is only a corruption, was besieged by Attila in 451, but relieved by the Romans, who here defeated Attila. It afterwards passed into the hands of the Franks, was taken by the Northmen in 855, and again in 865. In 1423, it was besieged by the English under the Duke of Bedford, but was delivered by Joan of Arc (q. v.), therefore named the Maid of O. In the wars of the 16th c., O. suffered severely. It was taken by the Germans in 1870, and was their centre of operations against the French army of the Loire.

ORLEANS, HOUSE OF. See **BOURBON**.

ORLEANS, JEAN BAPTISTE GASTON, DUC D', third son of Henry IV. of France and Marie de Medici; was born at Fontainebleau, 25th April 1608.

He possessed tolerable abilities, but his education was neglected. On his marriage with Marie of Bourbon, Duchess of Montpensier, in 1626, he received the duchy of Orleans as appanage. His wife soon died, leaving one daughter, the celebrated Mademoiselle de Montpensier. His brother, Louis XIII., regarded him with dislike as heir-presumptive to the throne, the queen having no children; and the treatment which he received at the hands of the king and of Richelieu, led him to join with his mother in attempting the overthrow of that minister. He left the court with a number of other great nobles in February 1631; sought the support of the Duke of Lorraine, whose sister he married; and raised in the Spanish Netherlands a corps of 2000 men, at the head of which he crossed the French frontier, assuming the title of Lieutenant-general of the Kingdom; but was completely defeated by Marshal Schomberg at Castelnaudary, and fled to the Duke of Lorraine, whom he thereby involved in ruin. In 1634, however, he returned to the French court. Richelieu sought to have his marriage with Marguerite of Lorraine declared invalid, but after a long struggle, and much disputing among jurists and theologians, its validity was sustained. The duke was, however, again obliged to leave France in consequence of fresh intrigues against Richelieu. After Richelieu's death, a reconciliation was effected between him and his brother, the king, by the ministers Mazarin and Chavigny; and Louis XIII. appointed him Lieutenant-general of the kingdom during the minority of Louis XIV. Mazarin and the queen-mother, Anne of Austria, attempting to assume all power to themselves, the duke placed himself at the head of the Fronde (q. v.); but with his usual vacillating weakness and selfish sacrifice of his friends, soon made terms again with the court. Yet, when Mazarin returned from banishment in 1652, the duke again assembled troops for the Prince of Condé, upon which account, after the disturbances were ended, he was confined to his castle of Blois, where he died on 2d February 1660. He left three daughters by his second marriage.

ORLEANS, NEW. See **NEW ORLEANS**.

ORLEANS, PHILIPPE, DUC D', regent of France during the minority of Louis XV., was the son of Philippe, Duc d'Orleans, and the grandson of Louis XIII., and was born 4th August 1674. He possessed excellent talents, and made unusual attainments both in science and belles lettres; but his tutor, Cardinal Dubois (q. v.), did not scruple to minister to the strong passions of the young prince, and exercised a most pernicious influence over him. He gave himself up to debauchery. The king compelled him to marry Mademoiselle de Blois, his daughter by Madame de Montespan. He astonished and alarmed the court by protesting against his exclusion by the testament of Charles II. from all right of succession to the throne of Spain, and by the attention which he immediately began to give to military and political affairs. His military talents, however, led to his employment in the wars in Italy and in Spain; but his presence in Madrid after his victories was regarded with apprehension both by Philip V. and by Louis XIV. He had, indeed, formed the design of taking possession of the Spanish throne for himself. In consequence of this, he lived for some years in complete exile from the court, and much dreaded by it; spending his time both in vicious excesses, and in the cultivation of the fine arts and the study of chemistry. This study afforded a pretext to Madame de Maintenon and her party for accusing him of poisoning the dauphin and others of the royal family, who died suddenly, and in rapid succession, of malignant fever, in 1711.

The king refused an investigation which the duke demanded. Louis, having legitimised his sons, the Duke of Maine and the Count of Toulouse, appointed the Duke of Orleans only president of the regency and not regent, giving the guardianship of his youthful heir and the command of the household troops to the Duke of Maine; but all this was set aside at his death, and the Duke of Orleans became sole regent. He was popular, and his first measures increased his popularity; but the financial affairs of the kingdom were perplexing, and the regent's adoption of the schemes of Law (q. v.) led to disastrous results. Meanwhile, on the 26th August 1718, he held the celebrated *Lit de justice*, in which he prohibited the parliament of Paris from meddling with financial or political affairs, and declared the legitimised sons of Louis XIV. incapable of succeeding to the throne. Dubois, who still possessed an unhappy influence over his former pupil, became prime-minister, and eventually ruler of France; the regent, who was really a man of far higher abilities, neglecting all duties, and pursuing a course of profligacy almost unequalled in the worst instances of antiquity. His eldest daughter, the Duchesse de Berry, followed his example, and brought herself to an early grave. Dubois, wishing to be made a cardinal, persuaded the regent to sacrifice the Jansenists, and to compel the parliament in 1722 to recognise the bull *Unigenitus* (q. v.). After the king's coronation, 15th February 1723, and the death of Dubois in August, the Duke of Orleans, although disliking public affairs, consented to become prime-minister; but died on the 2d December of the same year, physically exhausted by his incessant debauchery. The influence of his religious and other opinions, and the example of his immoralities, powerfully tended to promote that state of things which eventually produced the horrors of the French Revolution.

ORLEANS, LOUIS PHILIPPE JOSEPH, DUC D', born April 13, 1747, was the great-grandson of the preceding. He possessed very good abilities; but early fell into the grossest debaucheries, in which he continued to the end of his career. Louis XVI. disliked him on account of his debased character, and the queen for his obtrusiveness. He became gradually estranged from the court, sought popularity and obtained it, and embraced the cause of American independence. In the Assembly of Notables in 1787 he declared against the ministerial proposals; and when the king sought to overcome the resistance of the parliament by a *Lit de justice*, he protested against the proceeding. On the assembly of the States-General, he took the popular side, and voted with the extreme left in the National Assembly; seeking at the same time to please the populace by profuse expenditure, with the hope of being made Lieutenant-general of the Kingdom, or perhaps of opening for himself a way to the throne. When the insurrectionary movements began in Paris in 1789, he promoted them by secret agents and money. The court sent him on an ostensibly diplomatic mission to England, from which he returned after more than six months' absence, in July 1790, and unscrupulously engaged in new intrigues hostile to the king. But he began to find that he himself was made the mere tool of a party, who availed themselves of his influence and wealth for their own purposes, and this discovery cooled his revolutionary fervour. He withdrew from the Jacobin Club, was reconciled to the king, and appeared at court; but was treated with such disrespect by the courtiers, that he turned away, and from that time followed in blind rage the stream of the revolution. He joined Danton's party, was concerned in insurrections, disclaimed all pretensions

to the throne, renounced his titles, assumed the name of Philippe Egalité, was addressed as Citizen Egalité, and was returned by the department of Seine and Marne to the National Convention, in which he took his place among the Mountain party. He voted for the death of the king, being, it is said, himself threatened with death by the Jacobins if he should do otherwise, but alleging his sense of duty and his belief that every one who did anything contrary to the sovereignty of the people deserved death. The vote was received with a cry of disgust, and by no means increased the safety of his own position. The Mountain party were dissatisfied with him, because he did not give up the whole of his immense wealth for party purposes. After the desertion of his son, the Duke de Chartres (see LOUIS PHILIPPE), the decree for the imprisonment of all the Bourbons was applied to him. He was thrown into prison with his family in Marseille, and was brought before the tribunal of the department of Bouches de Rhône on a charge of high treason. He was acquitted, but the Committee of Public Safety immediately brought him before the Revolutionary Tribunal in Paris; and on the 6th of November 1793 he was condemned, and on the same day executed amidst the execrations of the multitude which had so often applauded him.

ORLEANS CLOTH, a kind of stuff made for ladies' dresses, in which the warp is of cotton and the weft of worsted. It is so called from having been first made at Orleans in France, but it is now extensively manufactured at Bradford in Yorkshire.

ORLOFF, or ORLOV, a Russian family that first rose to eminence during the reign of Paul III., when one of its members, Count Gregori O., attracted the notice of the Grand Duchess Catherine, afterwards the Empress Catherine II., and succeeded Poniatowski as her favourite. It was Gregori who planned the murder of Peter III., and his brother Alexis who committed the deed, and both received high honours and rich rewards for this and other services. The flourishing family of the Counts Bobrinski resulted from Gregori's intercourse with the empress. The legitimate line of O. soon became extinct; but Feodor, a brother of Gregori and Alexei, left four illegitimate sons, one of whom, Mikail, distinguished himself in the campaign of 1814; and another was Count Alexei O., the celebrated diplomatist. Count Alexei was born in 1787, signalled himself by courage and military talents during the French wars, negotiated the treaties of Adrianople (1829) and Unkiar-Skelessi (1833), and represented Russia at the London conference of 1832 on the affairs of Belgium and Holland. In 1844, he was placed at the head of the secret police; and the ability and energy with which he directed its vast machinery, rendered him the most dreaded official in Russia. He was high in the favour of the Emperor Nicholas, who employed him in the negotiations with Austria previous to the Crimean war. In 1856, he sat in the congress of Paris as the representative of Russia, and on his return was made president of the grand council of the empire. He died at St Petersburg, 20th May 1861.

O'LOP (Dutch, *overloop*, that which runs over, or covers), in ships of war, is the lowest deck, immediately above the hold. It contains the magazine, bread-room, and various store-rooms; and is used in time of action for the reception and treatment of the wounded, as, from being below the water-line, it is the safest part of the ship.

ORME'S HEAD, GREAT, a headland in the north-east of Caernarvonshire, North Wales, five miles north-north-west of Conway, is an enormous mass of limestone rock, surmounted by a

light-house, and forming the extreme point of the western shore of Orme's Bay. Lat. 53° 20' N., long. 3° 51' W.—Little Orme's Head forms the eastern extremity of the same bay.

ORMOLU is a variety of brass, consisting of zinc 25 parts, and copper 75 parts, which has a nearer resemblance in colour to gold than ordinary Brass (q. v.). It is extensively used for castings of ornaments for furniture, candelabras, and such articles. When the casting is made, its colour is brought out by a *pickle* of dilute sulphuric acid, after which the acid is removed by water, and a liquor varnish is put on to keep it from tarnishing.

ORMOND, JAMES BUTLER, DUKE OF, was the first of the ancient Anglo-Irish family of Butler on whom the ducal title was conferred. The family was of illustrious antiquity. Genealogical legend carried it back to the dukes of Normandy before the Conquest, and it is certain that at the dawn of the 13th c., it held the hereditary office of royal cup-bearer or *butler*, whence the family name.—The subject of the present article was born in London in 1610. His father, the son of the celebrated Walter, Earl of Ormond, was drowned in crossing the Channel; and the old earl having incurred the displeasure of the king, James I., and being thrown into prison, James, who on his father's death became, as Viscount Thurles, the heir of the title, was seized as a royal ward, and placed under the guardianship of the Archbishop of Canterbury. On the restoration of his grandfather to liberty, he also was released; and in his twentieth year he married his cousin, Lady Elizabeth Preston, and in 1632 succeeded, upon his grandfather's death, to the earldom and estates of Ormond. During the Strafford administration in Ireland, O. distinguished himself so much, that on Strafford's recall he recommended O. to the king; and in the rebellion of 1640, O. was appointed to the chief command of the army. During the troubled times which followed, he conducted himself with undoubted ability, although, as a necessary consequence of the numberless divisions and subdivisions of party which then prevailed in Ireland, he failed to satisfy any one of the conflicting sections; and when, in 1643, he concluded an armistice, his policy was loudly condemned as well by the friends as by the enemies of the royalist party in England. During the long contest of Charles with the parliament, O. continued to uphold the royal interest in his Irish government; and when the last crisis of the king's fortunes came, he resigned his Irish command, and retired to France, from which country he again returned to Ireland with the all but desperate design of restoring the royal authority, and after a gallant but unequal struggle, was compelled, in 1650, to return once more to France. His services to the royal cause continued unremitting during his exile; and at the restoration he accompanied Charles II. on his return, and was rewarded for his fidelity by the ducal title of Ormond. His after-life was less eventful, although he twice again returned to the government of Ireland. It was in 1679 that the well-known attempt was made by the notorious Colonel Blood (q. v.) upon the life of Ormond. As he was returning from a civic festival, he was attacked by Blood and a party of ruffians, and was dragged from his coach with the intention of his being hanged at Tyburn. The attempt drew additional interest from its being commonly supposed to have been instigated by the profligate Duke of Buckingham, O.'s inveterate foe. He escaped uninjured, and lived until the year 1688. His letters and other papers are full of deep historical interest. See *Carte's Life of Ormond*.

ORMSKIRK, a market town of England, in Lancashire, in the centre of a rich and populous agricultural district, 12 miles north of Liverpool by the Lancashire and Yorkshire railway. The parish church has both a tower and spire. Its grammar-school has an annual income from endowment of £150. Silk-weaving, rope-making, basket-making, and brewing are the principal branches of industry. There are large collieries in the vicinity. Pop. (1871) 6127; (1881) 6651.

ORMUZ, or HORMUZ, a small island in the strait of the same name, at the entrance of the Persian Gulf, and within ten miles of the Persian coast. It is about twelve miles in circumference, and belonged to the Imaum of Muscat till 1854. In the 16th c. it was taken by the Portuguese, and being made by them an entrepôt for goods from India, Persia, and Turkistan, it became important, and the town of the same name rose in population until it had 40,000 inhabitants. The town was demolished, in 1622, by Shah Abbās, assisted by the English, and its trade was removed to Gombroon (q. v.).

ORMUZD (Ahurmazd, Auramazda, Hormazd, Ormazd), corrupted from Ahur-Mazda, i. e., that Ahura (Vedic Asura) or 'Spiritual Being,' who is called Mazda (i. e. Vedic Medhās) = 'Creator of all things;' the name of the supreme deity of the ancient Persians, and of their descendants the Guebres and Parsees. It was at first emphatically employed in this sense by Zoroaster, or Zarathustra Spitama. O. is, according to Zoroaster's original doctrine, the creator of the earthly and spiritual life, the lord of the whole universe, in whose hands are all creatures. He is the light and the source of light, the wisdom and the intellect, and is in the possession of all good things, such as 'the good mind,' 'immortality,' 'wholesomeness,' 'the best truth,' 'abundance,' &c.; which gifts he bestows upon the pure in thoughts, deeds, and words, while the wicked are punished by him according to their wickedness. ('For thou art through purity, the holy over the wicked, the ruler over all, the heavenly, the friend of both worlds, Mazda! . . . Father of the pure creatures at the beginning, who hath created the way of the sun, of the stars, who causeth the moon to wax and to wane. . . . He holdeth the earth and the unsupported [heavenly bodies?], the waters and the trees, and giveth swiftness to the wind and the clouds. . . . The creator of the good mind, the working good, hath made light as well as darkness, sleep and waking, the morning dawns, the noons, the nights,' &c.—*Yazna*, 43.) Sprung from Zarvan-Akarana (the boundless time), i. e., being from eternity, self-existing, neither born nor created, he unites within himself—as does man and everything else existing—the two primeval principles of good and evil, the *Cvento-mainyus*—i. e., the white, holy spirit; and the *Angrō-mainyus* (corrupted into Ahriman) = the dark spirit. This Zoroastrian conception of the two sides of the divine being—itsself one and indivisible—has, however, in the course of time, partly through misunderstandings and wilfully false interpretations, undergone important changes. While the Zervan-Akarana was transformed by the Magi—in opposition to the Zendiks—into the Supreme Being itself, the philosophical notion of a duality in O. became the theological dogma of god and devil, jealous of each other's power, bent upon the destruction of each other's works, and consequently in constant war with each other, they and their armies. Both are—according to this corrupted view of later times, by means of which the genuine one has been forgotten up to our day—supreme rulers; both have their fixed number of councillors (sprung from

an egg, *Plut. Isis and Osiris*), who are the actual governors of the whole universe, each in his special province; which counsellors, however, are neither more nor less than certain abstract ideas of Zoroaster. One personal archangel alone is assumed by the latter, viz., Sraosha (Seroah, cf. Sanscr. Shruti), i. e., hearing, tradition. He is vested with very high powers, and stands between O. and man; he is the teacher of good religion; he shews the way to heaven, and pronounces judgment over human actions after death. He is the personification of the whole divine worship and its outward manifestations, the symbols, prayers, sacrifices, rites, &c., and the chief combatant of the influence of the Devas; who stand symbolically for the Brahmanic religion. O. is represented as sitting upon a throne of light, as a venerable man, or seated upon a bull, &c.—For further particulars about the seasons and the manner of his worship, as well as the general relations between his and the Brahmanic religion (both the result of a prehistoric conflict between the Iranians and those Arian brother-tribes who immigrated into Hindustan Proper), we must refer to PARSIS, PERSIA, and ZOROASTER.

ORNAMENTATION, or DECORATION, in Architecture, applies to something which is added to the simple constructive features, or to the form given to those features, for the purpose of making them beautiful or elegant. Thus, the Doric shaft, while answering the constructive purposes of a simple square or round pier, is ornamented with fluting; and its capital, with its beautifully proportioned echinus and abacus, supports as a plain slab would do the weight of the entablature. The other classic orders illustrate this in a richer manner. Thus, the Corinthian column, with its fluted and elegant shaft, resting on an ornamented base, and crowned by an ornamented capital, takes the place of what might have been, had utility alone been consulted, a plain pier of rubble-work, with a rough stone to rest upon, and another on the top to receive the load.

In classic architecture, as in every good style, the same principle pervades all the ornamental features—viz., *that they are constructive features ornamented in a manner suitable to their use*; for instance, a column being a member for support, should be of such a form as to denote this—the constructive use of a cornice being to protect the top of the wall, and to shield the front of it from the rain and sun, it should be made of such a form as to do this, and also to look as if it did it—to express its purpose. In classic architecture, the cornice consists of several members, in which the constructive decoration is well seen; the mutules and modillions beautifully indicating in an ornamental manner their original use, while the leaf enrichments of the small mouldings give life and animation to the building. In mediæval art the same principle prevails in a much greater degree, and over a more complex system of construction. The shafts, with their elegant and purpose-like bases and caps, are arranged so that each supports a separate member of the vaulting. The arch mouldings are divided so as to indicate the rings of their constructive formation. The buttresses, so elegant in outline, express the part they serve in supporting the vaulting; the pinnacles, with their ornamental finials, are the decorated dead-weights which steady the buttresses. The foliage and smaller ornament is also beautifully and suitably applied, as the growth and vigour of the supporting capitals and corbels, and the running foliage of the string-courses, arch-mouldings, &c., fully illustrate.

There are, no doubt, many styles of art to which these remarks can hardly be said to apply; as, for

example, the Assyrian, Egyptian, and Hindu styles, where we find many features applied in a manner meant to be ornamental, although actually contrary to their constructive use. In these styles (and also in Greek architecture), human figures, bulls, and other animals are placed as columns to carry the weight of a superincumbent mass. This is evidently wrong in principle, except when the figure is placed in an attitude to indicate that he is supporting a weight, as the Greek *Atlantes* do; but in the former cases religious notions seem to have overcome true artistic feeling. There are also many forms of ornament used in all styles, the origin of which is obscure, and their advantage doubtful; such are the zigzag, chevron, billet, &c., so common in early mediæval art, and the scrolls of Ionic and Indian art, and the complications of the interlacing work of the North in the middle ages. Such things may be admissible in coloured decoration, such as the confused patterns of Saracenic art, and the shell-patterns of Indian art; but where ornamental form is wanted, unless the requirements of the construction are carefully followed as the guide to the decoration, all principle is lost, and the ornament runs wild. This has frequently occurred in the history of art, and in no case more markedly than in the art of the Renaissance.

The material in use must also have an influence on the form and style of the ornament. Thus, stone-carving and metal-work must evidently require different treatment. Fac-simile leaves might be formed in iron, but could not be so carved in stone. This constructive element should be carefully attended to in designing. All imitative art must be to some extent conventional. Natural objects, such as leaves, flowers, &c., cannot be copied absolutely literally; and in suiting the conventional treatment to the nature of the material used, lies the great skill of the artist.

ORNE, a department of France formed out of the old provinces of Normandy and Perche, is separated on the north from the English Channel (La Manche) by the department of Calvados. Area, 2350 square miles, more than one-half of which is cultivable land; pop. (1881) 378,126. A range of wooded hills, nowhere rising above 1370 feet, extends across the south of the department from east to west. North of this range the surface slopes toward the English Channel; south of it, toward the Atlantic. The principal rivers are the Orne (which gives name to the department), the Rille, the Sarthe, and Huiane. The climate is damp, though in general temperate, and the winters are severe. The soil is fertile, but agriculture is not in an advanced state. The inhabitants consume one-third more grain produce than is grown on the land. There are several millions of apple and pear trees planted along the roads, &c., and cider is extensively made. Cattle, and horses of the purest Norman breed, are reared. Mining is an important branch of industry; the chief products are iron and copper; marble, granite, and other stones for building are quarried. The department is divided into four arrondissements, Alençon, Argentan, Domfront, and Mortagne; capital, Alençon.

ORNITHOLOGY (Gr. *ornis*, a bird, and *logos*, a discourse), that branch of zoology of which the subject is birds. By Aristotle, Pliny, and others of the ancients, this study was prosecuted to some extent, along with other parts of natural history; but it is only in modern times that ornithology has assumed the rank of a distinct branch of science. The first modern author to attempt a scientific classification of birds seems to have been Pierre Belon, noted also as an ichthyologist, whose *Historia*

Avium was published about the middle of the 16th century. Some of his classes are very heterogeneous assemblages; but the first three, viz., Birds of Prey, Web-footed Birds, and *Gralla*, are so natural as to have been acknowledged, with some modification of their limits, in all subsequent systems. In the 17th c. much progress was made in the observation and description of species, not only of the birds of Europe, but of other parts of the world. In the latter part of the century, attention began to be given to the anatomy of birds. An ornithological system, more perfect than that of Belon, was proposed by Willughby about 1676, and afterwards matured and improved by Ray. On this system that of Linné was founded. During the 18th c., the progress of ornithology was very rapid. The birds of many countries were described in works specially devoted to them, and the habits of birds began to be carefully observed; but the system of Linné, as framed by him before the middle of the century, continued to prevail almost unmodified till the publication of Cuvier's *Règne Animal* in 1817. Latham, Lacépède, Illiger, Temminck, and others, had indeed previously proposed systems more or less different from it; and systems have since been proposed by others, particularly by Mr Vigors and Mr Swainson, who have endeavoured to accommodate the classification to certain first principles which they supposed to pervade nature, but which other naturalists in general regard as fanciful. The system of Cuvier is now generally received by ornithologists, as that of Linné formerly was; not, however, without modifications, by which it has been sought to accommodate it to the progress of science, and some of the names introduced by other authors have obtained very general acceptance. The system of Linné divided birds into six orders—*Accipitres*, *Pica*, *Anseres*, *Gralla*, *Gallina*, and *Passeres*. That of Cuvier also divided them into six orders—*Birds of Prey* (the *Accipitres* of Linné, now often called *Raptores*), *Passerine Birds* (*Passerina*, now more generally called *Insectores*, or *Perching Birds*, including most of the Linnean *Passeres*, and part of *Pica*), *Climbers* (*Scansores*, part of the Linnean *Pica*, and often designated *Zygodactyli* or *Zygodactylous Birds*), *Gallinaceous Birds* (now often called *Rasores*, the Linnean *Gallina*, but including also the pigeons or *Columbidae*, which Linné placed among *Passeres*), *Still-birds*, often called *Waders* (*Grallatores*, the Linnean *Gralla*), and *Web-footed Birds* (*Palmipedes*, now also known as *Nataiores* or *Swimmers*). These orders are noticed in separate articles. Perhaps the most important modification of Cuvier's system which has been proposed, is the separation of the *Brevipennes* or *Struthious Birds* from *Gralla*, and their formation into a distinct order, sometimes called *Cursores* or *Runners*; and next to this may be mentioned the proposed separation of *Columbidae* from Gallinaceous Birds.—The progress of ornithology since the commencement of the 19th c. has been very rapid; every department of it has been assiduously cultivated, and many of the works published have been not only of great merit, but very sumptuous and beautiful. For Huxley's division of birds into three orders, see ZOOLOGY.

ORNITHORHYNCHUS. See DUCK-BILL.

OROBANCHÆ, or OROBANCHA'CEÆ, a natural order of exogenous plants, all herbaceous, and destitute of true leaves, but having their stems covered with brown or colourless scales. They all grow parasitically upon the roots of other plants. The calyx is divided, persistent, inferior; the corolla monopetalous, hypogynous, and irregular. The stamens are four, two long and two short; the ovary 1-celled, seated in a fleshy disc, composed of

two carpels, with one style. The fruit is capsular, enclosed within the withered corolla, 1-celled, 2-valved. The seeds are numerous, and very minute.

Broom-rape (*Orobancha rubra*):

a, the top of the stem, with bracts and flowers; b, the base of the stem, with scales; c, the corolla, cut open, showing stamens; d, the middle segment of the lower lip of the corolla, magnified, showing the beautiful fringe of gland-bearing hairs; e, capsule.

There are about 120 known species, natives chiefly of temperate climates, and generally characterised by astringency and bitterness, upon account of which some of them have been used in medicine (see CANCER ROOT). Eleven species are natives of Britain, chiefly belonging to the genus *Orobancha*, or BROOM-RAPE; to some of which important medicinal virtues were once erroneously ascribed. The enlarged base or rootstock of a species of *Orobancha* is cooked or dried, and eaten by the Indians of the north-western parts of America.

O'ROBUS, a genus of plants of the natural

Bitter Vetch (*Orobancha tuberosa*):

a, standard of the corolla.

order Leguminosæ, suborder Papilionaceæ, allied to Vetches, and sometimes called BITTER VETCH; the

style linear, downy beneath the stigma; the calyx obtuse at the base and oblique at the mouth; its upper segments deeper and shorter; the pod 1-celled, 2-valved; the leaves pinnate, without tendrils. The species are perennial herbaceous plants, chiefly natives of Europe. They afford good food for cattle. Two are natives of Britain, of which the most common is *O. tuberosus*, whose racemes of purple flowers often adorn heaths and bushy places, especially in hilly districts. The stem is unbranched, erect, about a foot high, with narrow membranous wings; the leaflets in 2-4 pairs; the pods long, cylindrical, black; the root creeping and swelling out into tubers at irregular intervals. The tubers have a sweet taste, resembling that of liquorice, and are sought after by children; they are also bruised and steeped in water in some parts of the Highlands of Scotland to make a fermented liquor, and a kind of liquor is made by steeping them in whisky; they are well-flavoured and nutritious when boiled or roasted, and are used in this way in the Highlands of Scotland, in Holland, Belgium, and other countries.

ORONTES, the ancient name of a river in Syria, now called *Nahr-el-Asi*. It rises in the highest part of Coele-Syria, near Baalbek, flows northward between the mountains of Libanus and Anti-Libanus, as far as the city of Antioch, and then westward to the Mediterranean Sea, after a course of 240 miles, passing by a cross valley, through the mountains of the Syrian coast. Its lower course is remarkably beautiful, surpassing everything else that can be seen in Syria. Its rocky banks are 300 feet high, and the windings of the river shew them off to the greatest advantage. Myrtle-bushes, laurels, figs, wild vines, arbutus, dwarf-oaks, and sycamores (*Acer pseudo-platanus*) are scattered about in picturesque confusion. Here and there the eye catches a glimpse of some cavern mouth or ivy-matted precipice, while from the abyss beneath ascends for ever the roar of the impatient stream. The country through which it flows is of great fertility, and in many parts is richly cultivated.

OROSIUS, PAULUS, a Spanish presbyter and historian, was born at Tarragona, and flourished in the early part of the 5th century. He went to Africa about 413 A.D., where he made the acquaintance of St Augustine, and thence to Palestine, to study under St Jerome, then living at Bethlehem. He finally settled in Africa, but the date of his death is unknown. His chief work, the *Historiarum adversus Paganos Libri* 7, begins with the creation and goes down to 417 A.D. It is apologetic in design, being intended to refute the notion then current among the pagans, that the misfortunes of the Roman Empire and the wretchedness of the great masses were owing to the anger of the gods at the abandonment of their worship, and the profanation of their altars. The work is a trivial, inaccurate, uncritical miscellany of facts, culled from such second-rate authorities as Justin and Eutropius; the style is elegant, but also, as Bacon says, 'watery.' Yet it has obtained a place in literature from being a favourite text-book of universal history during the middle ages, and had the honour of being translated into Anglo-Saxon by our own Alfred. Some manuscripts bear the puzzling title of *Formesta* or *Ormista*, conjectured by some to be a corruption of Or. M. 1st.; that is, *Orosii Mundi Historia* (Orosius's History of the World). The editio princeps of the work appeared at Vienna in 1471; the best edition is that of Haverkamp (Lug. Bat. 4to, 1738). Other writings of O.'s are *Liber Apologeticus de Arbitrii Libertate*, an anti-Pelagian treatise, *Commonitorium ad Augustinum*,

an explanation of the state of religious parties in Spain in his time. Editions of the *Historia* were published by Haverkamp (1738 and 1767) and Zangemeister (1881). See Möriener's work on O.

OROTAVA, a town on the north coast of Teneriffe, one of the Canary Islands, is situated below the Peak, in one of the most fertile, pleasant, and healthy districts in the world. It contains several beautiful churches, the residence of the governor and the citadel. Fishing is carried on to some extent, and there is a trade in wine. Pop. about 9000.

ORPHEUS (supposed to be the Vedic Ribhu or Arbhu, an epithet both of Indra and the Sun), a semi-mythic name of frequent occurrence in ancient Greek lore. The early legends call him a son of Apollo and the Muse Calliope, or of (Eragrus and Clio, or Polymnia. His native country is Thracia, where many different localities were pointed out as his birthplace—such as the Mounts of Olympus, and Pangæus, the river Enipeus, the promontory of Serrhium, and several cities. Apollo bestows upon him the lyre, which Hermes invented, and by its aid O. moves men and beasts, the birds in the air, the fishes in the deep, the trees, and the rocks. He accompanies the Argonauts in their expedition, and the power of his music wards off all mishaps and disasters, rocking monsters to sleep and stopping cliffs in their downward rush. His wife, Eurydice (? = Sanscr. Uru, Dawn), is bitten by a serpent (? = Night), and dies. O. follows her into the infernal regions; and so powerful are his 'golden tones,' that even stern Pluto and Proserpina are moved to pity; while Tantalus forgets his thirst, Ixion's wheel ceases to revolve, and the Danaides stop in their wearisome task. He is allowed to take her back into the 'light of heaven,' but he must not look around while they ascend. Love or doubt, however, draws his eyes towards her, and she is lost to him for ever (? = first rays of the sun gleaming at the dawn make it disappear or melt into day). His death is sudden and violent. According to some accounts, it is the thunderbolt of Zeus that cuts him off, because he reveals the divine mysteries; according to others, it is Dionysius, who, angry at his refusing to worship him, causes the Menades to tear him to pieces, which pieces are collected and buried by the Muses in tearful piety at Leibethra, at the foot of Olympus, where a nightingale sings over his grave. Others, again, make the Thracian women divide his limbs between them, either from excessive madness of unrequited love, or from anger at his drawing their husbands away from them. Thus far legend and art, in manifold hues and varieties and shapes, treat of O. the fabulous. The faint glimmer of historical truth hidden beneath these myths becomes clearer in those records which speak of O. as a divine bard or priest in the service of Zagreus, the Thracian Dionysius, and founder of the Mysteries (q. v.); as the first musician, the first inaugurator of the rites of expiation and of the Mantic art, the inventor of letters and the heroic metre; of everything, in fact, that was supposed to have contributed to the civilisation and initiation into a more humane worship of the deity among the primitive inhabitants of Thracia and all Greece: a task to which O. was supposed to have devoted his life after his return with the Argonauts. A kind of monastic order sprang up in later times, calling itself after him, which combined with a sort of enthusiastic creed about the migration of souls and other mystic doctrines a semi-ascetic life. Abstinence from meat (not from wine), frequent purifications and other expiatory rites, incantations, the

wearing of white garments and similar things—not unlike some of the Essenic manners and customs—were among their fundamental rules and ceremonies. But after a brief duration, the brotherhood, having first, during the last days of the Roman empire, passed through the stage of conscious and very profitable jugglery, sank into oblivion, together with their 'orphoeistic' formulas and sacrifices, and together with the joys of the upper, and the never-ending punishments of the infernal regions which they held out to their rich dupes: according to the sums they grudged or bestowed upon them.

O. has also given the name to a special literature called the Orphic, the real origin of which, however, is (according to Otfried Müller), like Orpheus's own history, 'unquestionably the darkest point in the entire history of early Greek poetry.' Like Olen, Linus, Philammon, Eumolpus, Musæus, and other legendary singers of prehistoric Greece, O. is supposed to have been 'the pupil of Apollo and the Muses,' and to have first composed certain hymns and songs used in the worship of a Dionysius, dwelling in the infernal regions, and in the initiations into the Eleusinian mysteries. A mere 'abstraction,' as it were, he was called the first poet of the heroic age, and though not mentioned before Ibycus, Pindar, Hellanicus, and the Athenian tragedians, he was yet placed anterior to both Homer and Hesiod. The fragments current under his name were first collected at the time of the Pisistratidæ, chiefly by Onomacritus, and these fragments grew under the hands of the Orphic brotherhood, aided by the Pythagoreans, to a vast literature of sacred mythological songs sung at the public games, chanted by the priests at their service, worked out for dramatic and pantomimic purposes by the dramatists, commented upon, philosophised upon, and 'improved' by grammarians, philosophers, and theologians. Although authorities like Herodotus and Aristotle had already combated the supposed antiquity of the so-called Orphic myths and songs of their day, yet the entire enormous Orphic literature which had grown out of them retained its 'ancient' authority, not only with both the Hellenists and the church fathers of the 3d and 4th centuries A.D. (who, for their individual, albeit opposite purposes, referred to it as the most authentic primitive source of Greek religion, from which Pythagoras, Heraclitus, Plato had drawn their theological philosophy), but down almost to the last generation, when it was irrefutably proved to be in its main bulk, as far as it has survived, the production of those very third and fourth centuries A.D., raised upon a few scanty, primitive snatches. The most remarkable part of the Orphic literature is its Theogony, which is based mainly on that of Hesiod, with allegorising and symbolising tendencies, and with a desire to simplify the huge Olympian population by compressing several deities into a single one. See THEOGONY. Yet there is one figure which stands out here prominently—viz., Zagreus, the horned child of Zeus by his own daughter Persephone, who, killed by the Titans at the bidding of Here, is reborn by Semele as Dionysius.

Besides the fragments of the Theogony which have survived, imbedded chiefly in the writings of the Neoplatonists, are to be mentioned the *Argonautica*, a poem of the Byzantine period, consisting of 1384 hexameters; further, a collection of 87 or 88 liturgical hymns; a work on the virtues of stones, called *Lythica*, &c. Other poems belonging to the Orphic Cycle, of which, however, only names have survived in most instances, are *Sacred Legends*, ascribed to Cercops; a Poem on Nature, called *Physica*, probably by Brontinus; *Bacchica*, supposed to be written by Avignota, the daughter

of Pythagoras; *Mynas*, or Orpheus's descent into the Hades; and other poetical productions by Zopyrus, Timocles, Nicias, Persinus, Prodicus, &c. The best edition of the Orphic fragments is that of G. Herrmann (Leipzig, 1805). The hymns have repeatedly been translated into English by T. Taylor and others. See Lobeck's *Aglaophamus* (1829); Gerhard, *O. und die Orphiker* (1861); and Schuster, *De Theogonia Orphica Indole* (Leipzig, 1869).

O'RPIMENT. See ARSENIC.

O'RRERY, a machine constructed for the purpose of exhibiting the motions of the planets round the sun, and of the satellites round their primaries, which was in high repute during the 18th and beginning of the 19th centuries, though now regarded as a mere toy. It was a combination of the old *Planetarium* (q. v.), with other machines which shewed the motions of the earth, moon, and planetary satellites. Though the construction of a machine which would exhibit accurately the motions, distances, and magnitudes of the planets is impossible, yet an orrery is in some degree useful as giving a general notion of the way in which the planetary motions are performed. As it was a favourite machine at one time, a description of it may not be uninteresting. A number of iron tubes equal in number to the planets, and of different dimensions, are placed one within the other; their lengths being arranged so that the innermost tube projects at both ends beyond the one next to it, that one similarly projects beyond the third, and so on. At one end of each tube a rod is fixed at right angles, and a ball or lamp attached to its end; the lengths of the rods being proportional (or at least supposed to be so) to the radii of the planetary orbits. The other ends of the tubes form the axes of toothed wheels, which are connected either directly, or by means of combinations of toothed wheels, with a winch. The several combinations of wheels are so adjusted that the velocity of revolution of the rods is proportional to the times of revolution of the planets. On turning the winch the whole apparatus is set in motion, and the balls or lamps (representing the planets) revolve round the centre, which is a fixed lamp (representing the sun), at different distances, and with varying velocities. There are many nice arrangements, such as for producing elliptic motion, but these need not be described.

O'RRIS ROOT (probably a corruption of *Iris* Root), the rootstock (*rhizome*) of certain species of *Iris* (q. v.), natives of the south of Europe, belonging to the division of the genus having bearded flowers, sword-shaped leaves, and scapes taller than the leaves; viz. *I. Florentina*, a species with white flowers; *I. pallida*, which has pale flowers; and *I. Germanica*, which has deep purple flowers. The flowers of all these species are fragrant. *I. Germanica* extends further north than the other species, and its root is sometimes said to be more acrid. O. R. was formerly used in many medicinal preparations as a stimulant, but is now almost entirely disused. It is sometimes chewed to sweeten an offensive breath. Its chief use is in perfumery. It has a pleasant smell of violets, which it acquires in drying. Hair and tooth powders, and oils, are often scented with it. A tincture of it is also used as a scent, and is often sold as *Essence of Violet*.

ORSINI, FELICE, an Italian revolutionist, who is destined to be remembered for his atrocious attempt on the life of the French emperor, Napoleon III., was born at Meldola, in the States of the Church, in 1819. The son of a conspirator, O. at an early age was initiated into secret societies, and before he had reached his twentieth year, he

was thrown into prison, and condemned to the galleys for life. The amnesty of Pius IX. (1846) restored him to liberty, but he was soon after again imprisoned for participation in political plots. When the revolution of 1848 broke out, O. was elected as a deputy to the Roman Constituent Assembly. He was invested with extraordinary powers, and sent to Ancona and Ascoli to suppress brigandage. He signalised himself by the violence with which he executed his commission. He also took part in the defence of Rome and Venice; agitated in Genoa and the Duchy of Modena; and in 1853 was shipped for England by the Sardinian government, where he formed close relations with Mazzini. Furnished with money by the leaders of the revolutionary party, he appeared at Parma in 1854, and afterwards at Milan, Trieste, Vienna, everywhere agitating in the interest of insurrection; until at last he was arrested and confined in the fortress of Mantua. In 1856 he succeeded in making his escape, and found refuge in England, where he supported himself by public lecturing, and wrote a book entitled *The Austrian Dungeons in Italy* (Lond. 1856). Towards the end of 1857 he repaired to Paris, with the intention of assassinating Louis Napoleon, whom he reckoned the great obstacle to the progress of revolution in Italy. His associates in this diabolical design were persons named Pieri, Rudio, and Gomez. Providing themselves with bombs, they took up their station in a house close by the opera, and on the evening of the 14th January 1858, just as the carriage containing the emperor and empress was drawing up, they threw three of the deadly missiles under the carriage. An explosion took place, and several people were wounded, one or two mortally, but their majesties remained unhurt. The assassins were arrested, tried, and sentenced; O., Pieri, and Rudio to capital punishment, Gomez to hard labour for life. Rudio's life was spared at the intercession of the empress, but Pieri and O. were beheaded on March 13.

ORSOVA, the name of two towns at the Iron Gates of the Danube (q. v.). OLD O., a Hungarian place, is on an island, and is a station for the Danube steamers. Pop. 1200.—NEW O., on the Servian side, is a fortified town of 3000 inhabitants.

ORTHEZ, a small town of France in the department of Basses-Pyrénées, on the right bank of the Gave de Pau, 37 miles east of Bayonne. Pop. about 5000. The castle of Moncada, now reduced to a few ruined walls, overtopped by one stately tower, was built here in 1240 by Gaston de Foix. In the immediate vicinity of the town, the British, under Wellington, gained a grand and decisive victory over the French under Soult, February 27, 1814.

ORTHIS (Gr. *straight*), a large genus of fossil brachiopodous mollusca, found in the Palæozoic rocks, most abundantly in the Silurian rocks, but ranging upwards to the Permian series. The genus contains upwards of 100 species.

ORTHO CERAS (Gr. *straight horn*), an extensive genus of cephalopodous mollusca, found in the palæozoic rocks, from the Lower Silurian to the Trias. It is nearly allied to the Nautilus, and is indeed, in its simplest forms, nothing more than an unrolled and straightened nautilus. The shell is straight, the siphuncle central, and the body chamber small. The members of the genus are the most widely distributed, and the most abundant of any of the palæozoic fossils. Nearly 200 species have been described, but a considerable number of these have been separated into sub-genera, characterised chiefly by the form and size of the siphuncle.

ORTHODOXY (Gr. *orthos*, right, and *doxa*, an opinion), a name given by theologians to religious

opinions in agreement with Scripture, or rather with the view of Scripture entertained either by the church in general, or by the Established Church of any particular nation. Its antithesis is HETERO-DOXY (Gr. *heteros*, another, meaning 'wrong,' and *doxa*, opinion).

ORTHOEPEY (Gr. correctness or propriety of speech), a branch of grammar that treats of the right pronunciation of the words of a language.

ORTHOGRAPHY (Gr. correct writing), a branch of grammar that treats of the elementary sounds of a language, the signs or letters by which they are represented in writing, and the combinations of these signs to represent words; it also includes the right dividing of words into syllables (as when a word has to be divided at the end of a line), and punctuation. In a more restricted sense, orthography is synonymous with the art of correct spelling. No part of grammar is less satisfactory than this. All alphabets were from the first both defective and redundant, and therefore inadequate to represent exactly the elementary sounds of the languages to which they were applied (see ALPHABET, LETTERS AND ARTICULATE SOUNDS). The first attempts then at writing any language must have exhibited great diversity of spelling. Wherever an extensive literature has sprung up among a people, and language been made a study of itself, there a greater or less uniformity of spelling has, by tacit convention or otherwise, become established for a time. Such was the case with Latin in the time of the Cæsars, with High German about the 12th and 13th centuries, and with English (Anglo-Saxon) in and for some time after the days of Alfred. But although language, as depicted to the eye, may be fixed for a time, the spoken tongue, being a living organism, cannot be thus petrified. A written literature may modify, and in some degree retard, but cannot altogether arrest that incessant change and evolution to which all spoken tongues are subject. The breaking up of the Anglo-Saxon in its transition into modern English, brought necessarily a period of orthographic chaos. Never was the lawlessness greater than during one of the brightest periods of the literature, namely, the Elizabethan period. Then, and for a long time after, all perception of the real powers of the letters seems to have been lost, and nothing but caprice ruled. Not only were words spelled differently by different persons, but even among the best educated classes the same person would spell the same word (even his or her own name) half-a-dozen ways in the same page. Among the classic writers of the Queen-Anne period, some degree of uniformity began to establish itself, and this was afterwards further confirmed and fixed by the publication of Johnson's Dictionary, since which time the alterations have been comparatively trifling. The modern spelling thus established, conformed itself only partially to the changes the spoken language had undergone. Of the letters that had become silent through the wearing away and collapse of the spoken words, some were omitted and others retained, with little attention to consistency, or to any principle now discernible. Hence, in the English language as now written and spoken, there is in general so imperfect a correspondence between the sound of a word, and the sounds of the several letters that are written to represent it, that the spelling of each individual word has, in a manner, to be learned by itself. By no possible rules can a learner be taught when he sees the groups of letters *n-o-w*, *p-l-o-u-g-h*, *e-n-o-u-g-h*, to make out the sounds or spoken words, when these groups actually represent; or, conversely, when he hears

the words spoken, to find out what letters they are to be represented by. This circumstance presents great difficulty to foreigners in the acquisition of English; which, in other respects, is one of the simplest and most easily learned languages in the world. The orthography of English is only to be acquired by observation and practice. There are no *rules* in the proper sense of the word; the only effective assistance that can be given in this matter is to bring together, under some kind of classification, the words that are most frequently misspelled. See PHONETIC WRITING.

ORTHOPTERA (Gr. straight-winged), an order of mandibulate insects, in many respects resembling the *Coleoptera* (q. v.), but having the wing-covers softer and generally leathery and flexible. The wing-covers also often overlap on the back when at rest, or meet at an angle like the roof of a house. The wings are broader than the wing-covers, and fold in a fan-like manner. A few species are wingless. The body is generally elongated. The antennae are almost always filiform and many-jointed. The eyes are usually very large, and there are also in most species two or three stemmatic eyes. The mouth much resembles that of the *Coleoptera*, but the maxillae are terminated by a horny denticulated piece, and covered by a *galea*; and the interior of the mouth exhibits a distinct fleshy piece, which some regard as a kind of tongue. The *O.* undergo only a semi-complete metamorphosis, the larva and pupa much resembling the perfect insect, except in the want of wings; which, however, begin to be developed in the pupa. The Earwig family differs so much from the other *O.* as to have been constituted by some entomologists into a distinct order. See *EARWIG*. The *O.* are divided into two sections, *Cercaria* and *Saltatoria*; the first with legs adapted for running, as the Mantis family, Spectre Insects, Walking Sticks, Leaf Insects, &c.; the second having the hinder legs very large and strong, generally adapted for leaping, as Grasshoppers, Locusts, Crickets, &c.

ORTOLAN (*Emberiza hortulana*), a species of Bunting (q. v.), much resembling the Yellow Hammer, and not quite equal to it in size. The

Ortolan (*Emberiza hortulana*).

adult male has the back reddish brown, the wings dusky black and rufous brown; the tail dusky black, some of the outer tail-feathers with a patch of white on the broad inner web; the chin, throat, and upper part of the breast yellowish-green; the other under parts reddish buff-colour. The plumage of the female is of less vivid hues. The *O.* occurs in great flocks in the south of Europe and north of Africa. Even in the south of Europe it is a summer bird of passage, but its migrations extend as far north as Lapland, although in Britain it is a very rare bird, and only of accidental occurrence. It has no song, but merely a monotonous chirping note.

It frequents bushy places, but often makes its nest on the ground in cornfields, particularly where the soil is sandy. No bird is so highly esteemed by epicures, and vast numbers are used for the table. It is taken chiefly by nets, with the aid of decoy-birds, and after being taken is fattened on millet and oats, in rooms dimly lighted by lamps. Thus treated, it becomes excessively fat, sometimes so as to die of obesity; and attains a weight of three ounces. Great numbers of ortolans, potted and pickled, are exported from Cyprus.

ORTONA, a town of S. Italy, on the Adriatic, in the province of Chieti, 14 miles E. of the town of that name, and 8 miles N. of Lanciano. It gives title to a bishop, and contains a cathedral and other religious edifices. Its port has ceased to exist, and vessels are now obliged to anchor about a mile from the town in unsheltered roads, where, however, the water is deep and the bottom good. Wine is extensively grown, and has a local reputation as the best in this part of Italy. Pop. about 7000.

ORTYX. See VIRGINIAN QUAIL.

ORVIETO, a city in the province of Umbria (Perugia), which was included in the former Papal States, but now forms part of the kingdom of Italy, stands on the right bank of the Paglia, 8 miles north-east of Lake Bolsena, and 60 miles north-north-west of Rome. It occupies a strong position on a steep hill, is well built, and is surrounded with walls. It has been the seat of a bishop since 509 A.D. The cathedral, a beautiful specimen of the Italian Gothic, and one of the most richly-decorated edifices in Italy, is built of black and white marble, was begun in 1290, and completed about the middle of the 14th century. The façade is unsurpassed in richness of material, and in the beauty of its mosaics, sculptures, and elaborate ornamentation. The interior is also magnificently decorated with sculptures and paintings. The other chief buildings are St Patrick's Well, and several palaces. Pop. 7500, who trade in corn, cattle, and silk, and a delicate white wine, which is highly esteemed at Rome.

O., called in the time of the Longobards *Urbs Vetus*—of which its present name is a corruption—has been the place of residence and retreat in turbulent times of upwards of 30 popes. The city is evidently of Etruscan origin, but of its early history nothing is known.

O'RYX, the name given by the ancients to a species of antelope, a native of the north of Africa.

Oryx.

It is often represented on the monuments of Egypt, and as these representations are almost always in profile, it is generally made to appear as having

only one horn, thus probably contributing to the fable of the unicorn; and, indeed, all the older figures of the unicorn exhibit a considerable resemblance to this kind of antelope. The name *Antelope oryx* was given by Pallas to the Gems-boc (q. v.), an antelope certainly much resembling the O., but found only in South Africa; and it is now generally believed that the true O. of the ancients is a species also known as the ALGAEEL (*Antelope Gazella*, or *Oryx beuaticus*), common in the north of Africa.

ORYZA. See RICE.

OSA'OA, or OZAKA, a city of Japan, in N. lat. 35° 5', about 20 miles from its seaport of Hiogo, is situated on a large river on the south-east coast of the main island, in the most central and populous part of the empire, and surrounded by the great tea districts. O. is one of the three imperial cities of Japan, and is a great centre of trade; especially since 1863, when it became possible for foreigners to settle. The town, clean and regularly built, is intersected by numerous streams, spanned by hundreds of wooden and iron bridges. Some of the public buildings are imposing structures, such as the municipal hall and the new mint. The latter is equipped with the finest obtainable apparatus; and of late much foreign machinery has been introduced into O., to the great advancement of its manufactures. Besides very numerous Buddhist and other temples, there are in O. two Christian churches, a government college, an academy, and 72 public schools. The town is connected by railway with Hiogo and with Kioto (see MIAKO), 27 miles further inland. Pop. (1877) 281,119. The foreign imports are valued at near £100,000 annually; the exports at £200,000.

OSAGE ORANGE (*Machura aurantiaca*), a tree of the natural order *Moraceae*, a native of North America. It attains a height varying, according to soil and situation, from twenty to sixty feet. It is of the same genus with *Fustic* (q. v.), and its wood, which is bright yellow, might probably be used for dyeing. The wood is fine-grained and very elastic, and is much used by the North American Indians for making bows. The O. O. has been successfully introduced into Britain as a hedge plant. Its fruit is about the size of a large orange, has a tuberculated surface of a golden colour, and is filled internally with radiating somewhat woody fibres, and with a yellow milky juice, the odour of which is generally disliked, so that the fruit, although not unwholesome, is seldom eaten.

O'SBORNE or ST HELEN'S BEDS are a series of strata of the Middle Eocene period, occurring in the Isle of Wight. They have been divided into two groups: 1. The St Helen's Sands, consisting of layers of white, green, and yellow sands, interstratified with blue, white, and yellowish clays and marls, with a maximum thickness of 50 feet; and, 2. the Nettlestone Grits, composed of yellow limestone and marl, and a shelly freestone, which is much used for building, having a maximum thickness of 20 feet. The fossils of the Osborne Beds are species of *Paludina* and *Cypria*, and the spirally sculptured spore-cases of *Chara*. The group is of fresh and brackish water origin, and is very variable in mineral character and thickness.

OSCAR I., JOSEPH-FRANÇOIS, king of Sweden and Norway, was born at Paris, July 4, 1799, and was the only issue of the marriage of Charles XIV. (q. v.), formerly Marshal Bernadotte, with Desirée Clary, the daughter of a Marseillais merchant, and sister of Madame Joseph Bonaparte. After the election of his father as crown-prince of Sweden, O. received the title of Duke of Sudermania, and was placed

under the tutelage of the poet Atterbom, for the purpose of acquiring the Swedish language. In 1818, he entered the university of Upsala, where his education was completed. The effects of the thorough training he received were seen in his remarkable proficiency in science, literature, and especially the fine arts. For some time he gave himself up almost entirely to the study of music, and composed various pieces, including an opera, and several waltzes, marches, &c.; he is also the author of several songs and hymns, some of which are still popular. He also published memoirs on Education and Penal Establishments. What is of more consequence, he became thoroughly imbued with the national sentiments, and after his admission to a share in the administration, opposed, though with becoming filial respect, the pro-Russian policy of his father. This course of conduct rendered him immensely popular, and on March 8, 1844, his accession to the throne was hailed with rapture by the great majority of his subjects. His rule was distinguished for its liberality and justice; and many liberal measures, such as those for the removal of Jewish disabilities, freedom of manufactures and commerce, and parliamentary reform (the last mentioned being vigorously opposed by the nobility), were laid before the *Riksdag* by his orders. He introduced these changes with caution and gentleness, and had the gratification of seeing, in most cases, his prudence crowned with success. His foreign policy was of an independent and anti-Russian character, and during the Crimean war he joined (November 21, 1855) the king of Denmark in a declaration of armed neutrality, which gradually assumed a more hostile attitude to Russia, and would have inevitably led to war, had not the Paris treaty so rapidly succeeded. His attitude at this time gained him general favour and respect throughout Europe. On July 19, 1823, he married Josephine Beauharnais, the granddaughter of the Empress Josephine, by whom he had five children, the eldest of whom, on account of his father's failing health, was appointed regent, September 25, 1857, and succeeded to the throne as Charles XV. on the death of O., July 8, 1859. Charles XV. died 18th September 1872, and was succeeded by his brother as Oscar II.

OSCEOLA (Seminole, *As-se-ho-lar*), a chief of the tribe of Seminole Indians in Florida, U.S., was born about 1803. He was the son of an English trader, named Powell, and the daughter of a Seminole chief. In 1835 the wife of O., a chief's daughter, was claimed and seized as a slave by the owner of her mother. The outraged husband threatened revenge, and for his threats was imprisoned six days in irons by General Thompson. Lying in wait, a few days afterwards he killed the general and four others. This was the beginning of the second Seminole war. Laying an ambush soon after, he killed Major Dale and a small detachment of soldiers, and taking to the almost impenetrable Everglades, with two or three hundred followers, he fought for a year with great energy and skill the superior numbers sent against him. He was taken prisoner at last by General Jessup, while holding a conference under a flag of truce, an act of inexcusable treachery, though represented as one of retaliation, and confined in Fort Moultrie until his death in January 1838.

O'SCI, originally OPSCI (rendered by Mommsen, 'labourers,' from *opus*, a work), in Greek always OPIKOI, the name of an Italian people, who at an early period occupied Campania, and were either closely allied to, or the same race as the Ausones. Subsequently (about 423 B. C.)

Samnites from the hilly districts to the north overran the country, and amalgamated with the inhabitants whom they had subjugated. It is conjectured that the conquerors were few in numbers, as (like the Normans in English history) they adopted in time the language of the conquered, but whether they modified the original Oscan language, and if so, to what extent, cannot now be ascertained. As it was these Samnitic Oscans or Campanians who formed that Samnitic people with whom both the Greeks of Lower Italy and the Romans first came into contact, the names *Osci* and *Oscan language* were subsequently applied to all the other races and dialects whose origin was nearly or wholly the same. The Oscan language was not substantially different from the Latin, but only a ruder and more primitive form of the same central Italic tongue. The territory where it was spoken comprised the countries of the Samnites, Frentani, Northern Apulians, Hirpini, Campani, Lucani, Bruttii, and Mamertini, whose dialects only slightly differed from each other; besides the entire Samnitic races, whence the language is sometimes called Samnitic or Safinic. The races situated north of the Silarus were purely Samnitic; those south of it, and even of the region round the Gulf of Naples, were Græco-Samnitic. The use of the national Samnitic alphabet was confined to the former. By the victories of the Romans over the Samnites, and the conferring of the *civitas* on all the Italians (88 B.C.), an end was put to the official use of the Oscan tongue; nevertheless, in the time of Varro (1st c. B.C.) it was still used by the people, and as late as the destruction of Herculaneum and Pompeii was spoken by a few individuals. During its most flourishing period it was something more than a country *patois*; it is even possible that the Oscans had a literature and art of their own, which may not have been without influence on the early Calabrian poets, Ennius and Pacuvius, and the Campanian Lucilius. At any rate, we certainly know of a poetic creation peculiar to the Campanians, a kind of unwritten, regular, probably improvised farce, with fixed parts and changing situations, which was transplanted to Rome about 304 B.C., but was imitated there not in Oscan but in Latin. See *ATELIANÆ*. Besides a considerable number of coins with Oscan legends, there are still extant a number of inscriptions in the Oscan tongue, among which the most important for linguistic purposes are, 1st, the *Tabula Bantina*, a bronze tablet found in the neighbourhood of Bantia (on the borders of Lucania and Apulia), referring to the municipal affairs of that town; 2d, the *Cippus Abellanus*, or Stone of Abella (in Campania); and 3d, a bronze tablet found near Agnone, in Northern Samnium. See Mommsen's *Oskische Studien* (Berlin, 1845), and *Die Unteritalischen Dialekte* (Leip. 1850); also Friedländer's *Die Oskischen Münzen* (Leip. 1850), Kirchhoff's *Das Stadtrecht von Bantia* (Berl. 1853), and Donaldson's *Varronianus* (pp. 104–138).

OSCULATION AND OSCULATING CIRCLE (Lat. *osculari*, to kiss). One curve is said to osculate another when several points are common to it with the other, and the degree of osculation is said to be high or low according as the number of points in contact are many or few. The number of possible points of contact is determined by the number of constants contained in the equation to the tangent curve (supposing the number of constants in the equation to the curve which is touched to be greater). The same is true of a straight line and a curve. The equation to a straight line being of the form $ax + b$, contains two constants, a and b , hence a straight line can coincide with a curve in two contiguous points, and the contact is said to

be of the *first* order. This straight line is the tangent at the point of contact. When a straight line, not a tangent, meets a curve, there is no 'contact' but 'section,' as in that case only one point is common to the straight line and the curve. The equation to a circle contains three constants, and therefore a circle can have *three* consecutive points in common with a curve, and the contact is then of the *second* order. This circle is known as the 'circle of curvature,' or the osculating circle (see Fig. of article *CURVATURE*), and has for its radius the radius of curvature of that portion of the curve with which the circle is in contact. No other circle can have so high a degree of contact with a curve at any point as the osculating circle at that point.

O'SHKOSH, a town in Wisconsin, U.S., on both sides of the Fox River, at its entrance to Lake Winnebago, 90 miles north-north-east of Madison. It has a large lumber trade, saw-mills, planing-mills, steamboats, &c. Pop. (1870) 12,663; (1880) 15,749.

OSIANDER, ANDREAS, one of the most learned and zealous of the German reformers, was born in 1498, at Gunzenhausen, near Nürnberg. His father was a blacksmith, called Hosemann, out of which name his son, after the fashion of his time, manufactured the classic-looking *Osiander*. O. was educated at Ingolstadt and Wittenberg; and after completing his course of study, became a preacher at Nürnberg, where he was conspicuously active in introducing the Reformation (1522). He ardently advocated the views of Luther in his controversy with the Swiss reformer Zwingli, on the question of the Lord's Supper. He took part in the conference held at Marburg (1529), and was present at the diet of Augsburg (1530). In 1548 he was deprived of his office as preacher at Nürnberg, because he would not agree to the Augsburg Interim; but was immediately afterwards invited by Albrecht, Duke of Prussia, to become the head of the theological faculty in the newly-established university of Königsberg. He was hardly settled here when he became entangled in a theological strife that embittered his naturally imperious and arrogant temper. In a treatise, *De Lege et Evangelio* ('On the Law and the Gospel'), O. asserted that the righteousness by which sinners are justified, is not to be conceived as a mere justificatory or imputative act on the part of God, but as something inward and subjective, as the impartation of a real righteousness, springing in a mystical way from the union of Christ with man. The most notable of his opponents was Martin Chemnitz (q. v.). A seemingly amicable arrangement between the disputants was brought about by Duke Albrecht in 1551; but the strife was soon recommenced, by O. publishing some new writings in which he attacked Melancthon; nor did his death in the following year put a stop to the war of words. It was continued by his followers, called *Osiandriæ*, who were finally extinguished by the *Corpus Doctrinæ Prutenicum* (in 1567), which caused their banishment from all parts of Prussia. See Wilken, *Andr. Osiander's Leben, Lehre und Schriften* (Strals. 1844).

O'SIER (Fr. probably of Celtic origin), the popular name of those species of Willow (q. v.), which are chiefly used for basket-making and other wicker-work. They are of low bushy growth, few of them ever becoming trees, their branches long and slender; and they are the more valuable in proportion to the length, slenderness, suppleness, and toughness of their branches. Their leaves are long and narrow, lanceolate, or nearly so, obscurely notched on the margin, almost always smooth on the upper side, but generally white and downy beneath. The

COMMON O. (*Salix viminalis*), a common native of wet alluvial grounds in Britain and many parts of Europe, is one of those which sometimes become trees, although when cultivated for basket-making, it is not permitted to do so. It has two distinct stamens in the flowers of the male catkins; and the stigmas of the female catkins are long and slender. It is often planted to prevent the banks of rivers from being washed away. Its branches are used for making hoops and coarse baskets. There are several varieties in cultivation, not easily distinguished except by a very practised eye, but much more useful than the original or wild kind, which is apt to break, and therefore of little value. More suitable for the finer kinds of basket-making are *Salix Forbyana*, sometimes called the **FINE BASKET O.**, and *S. rubra*, known near London as the **GREEN-LEAVED O.** or **ORNARD**; *S. triandra*, a triandrous species, known to English osier-cultivators and basket-makers as the **SPANIARD ROD**; whilst *S. vitellina*, a pentandrous species, sometimes becoming a tree, is the **GOLDEN O.** or **Golden Willow**, remarkable for the bright-yellow colour of its branches, as well as for their pliancy and toughness. There are other species, not natives of Britain, which are also valuable; but the osiers chiefly cultivated belong to those which have been named, or are very nearly allied to them.

Osiers are very extensively cultivated in Holland, Belgium, and France, on alluvial soils, especially near the mouths of rivers; and from these countries great quantities of 'rods' are imported into Britain. They are cultivated also to a considerable extent in some parts of England, particularly on the banks of the Thames and the Severn, and in the level districts of Cambridgeshire, Huntingdonshire, &c. They are nowhere extensively cultivated in Scotland. Islets in the Thames and other rivers, entirely planted with osiers, are called *O. holts*. Osiers grow particularly well on grounds flooded by the tide. Much depends on the closeness of planting of O. grounds; as when space is too abundant, the shoots of many of the kinds do not grow up so long, slender, and unbranched as is desirable. The French cultivators, when they wish osiers for the finest kinds of basket-work, cut branches into little bits with a bud or eye in each, and plant these pretty close together, so as to obtain weak but fine shoots; but generally cuttings of fifteen or sixteen inches in length are used, and of tolerably thick branches; and these are placed in rows, from 18 inches to 2 feet apart, and at distances of 15 to 18 inches in the row. O. plantations in light soils continue productive for 15 or 20 years, and much longer in rich alluvial soils. Osiers succeed best in rich soils, but not in clays. No cultivation is required after planting; but the shoots are cut once a year, at any time between the fall of the leaf and the rising of the sap in spring. After cutting, they are sorted; and those intended for brown baskets are carefully dried and stacked, care being taken that they do not *heat*, to which they are liable, like hay, and by which they would be rotted and rendered worthless. The stacks must be carefully protected from rain. The osiers intended for white baskets cannot at once be peeled; but after being sorted, they are placed upright in wide shallow trenches, in which there is water to the depth of about four inches, or in rivulets, being kept secure in their upright position by posts and rails; and thus they remain till they begin to bud and blossom in spring, which they do as if they remained on the parent plant, sending forth small roots at the same time into the water. They are then, in ordinary seasons, easily peeled by

drawing them through an instrument called a *break*, but in cold springs it is sometimes necessary to lay them for a while under a quantity of litter. After being peeled, they are stacked, preparatory to sale.

It is impossible to form an estimate of the quantity produced in Great Britain, but our imports amount annually to about 200,000 bundles; nearly one-half are from Holland, and the remainder from the Hanse Towns, Belgium, and France.

OSIRIS, according to others, *Asiris*, or *Hysiris* ('Many-eyed'), a celebrated Egyptian deity, whose worship was universal throughout Egypt. This name appears in the hieroglyphic texts as early as the 4th dynasty, and is expressed by a throne and eye; at a later period, that of the 19th, a palanquin is substituted for a throne; and under the Romans, the pupil of the eye for the eye itself. O. does not indeed appear to have been universally honoured till the time of the 11th and 12th dynasties, or about 1800 B.C., when Abydos, which was reputed to be his burial-place, rose into importance. In the monuments of this age he is called great god, eternal ruler, dwelling in the west, and lord of Abut or Abydos. Even at the most remote period, individuals after death were supposed to become an Osiris; and all the prayers and ceremonies performed or addressed to them were in this character, referring to their future life and resurrection. At the time of the 18th dynasty, this title of Osiris was prefixed to their names, and continued to be so till the time of the Romans and fall of paganism.

In the Ritual, and other inscriptions, O. is said to be the son of Seb or Saturn, and born of Nu or Rhea; to be the father of Horus by Isis, of Anubis, and of the four genii of the dead. Many mystic notions were connected with O.; he was sometimes thought to be the son of Ra, the Sun, or of Atum, the setting Sun, and the Bennu or Phoenix; also to be uncreate, or self-engendered, and he is identified in some instances with the Sun or the Creator, and the Pluto or Judge of Hades. O. was born on the first of the Epagomenæ, or five additional days of the year. When born, Chronos or Saturn is said to have given him in charge to Pamylen; having become king of Egypt, he is stated to have civilised the Egyptians, and especially to have taught them agriculture, the culture of the vine, and the art of making beer; he afterwards travelled over the earth, and conquered the people everywhere by his persuasion. During his absence, his kingdom was confided to Isis, who guarded it strictly, and Set or Typhon, the brother of O. (who was born on the 3d of the Epagomenæ), was unable to revolt against him. Typhon had, however, persuaded 72 other persons, and Aso, the queen of Ethiopia, to join him in a conspiracy; and having taken the measure of O., he had a chest made of the same dimensions, richly ornamented and carved, and produced it at a banquet, where he promised to give it to whosoever it should fit; and when all had lain down and tried it, and it suited none, O. at last laid himself down in it, and was immediately covered over by the conspirators, who placed the lid upon it, and fastened it with nails and molten lead. The chest was then hurled into the Nile, and floated down the Tanaitic mouth into the sea. This happened on the 17th of the month Athyr, in the 28th year of the reign or age of Osiris. Khem or Pan, and his attendant deities, discovered the loss of the god; Isis immediately cut off a lock of hair and went into mourning, and proceeded in search of Anubis, the child of her sister Nephthys by O.; and having found him, brought him up. The chest having floated to Byblos, had lodged in a tamarisk, and became enclosed in the

tree, which was cut down by the king, and the trunk, containing the chest and the body of the god, converted into a pillar to support the roof of the palace. The goddess proceeded to Byblos, and ingratiated herself with the queen's women by plaiting their hair and imparting to it an ambrosial smell, so that the monarch, whose name was Melcartus, and his wife, Saosis or Nemanoun, invited her to court to take care of the royal child. She endeavoured to confer immortality upon him by placing him on a fire, and changing herself into a swallow, flew round the pillar and bemoaned her fate. The queen became alarmed at the danger of her child; Isis revealed herself, and asked for the pillar of tamarisk wood, which was given her. She then cut it open, and took out the chest, making great lamentations, and subsequently sailed for Egypt, with the eldest of the king's sons. The goddess, intending to visit Horus her son at Buto, deposited the chest in an unfrequented spot; but Typhon discovered it by the light of the moon, tore it into 14 pieces, and distributed each to a nome or district. Isis recovered all by passing the marshes in a boat of papyrus; all except the phallus, which had been eaten by the Lepidotus, the Phagrus, and Oxyrhynchus fish. Subsequently, a battle took place between Horus and Typhon or Set, which lasted three days, and ended by Typhon having fetters placed upon him. Isis, however, liberated Typhon, which so enraged Horus that he tore off her diadem, but Teti or Thoth placed on her the head of a cow instead. Typhon finally accused Horus of illegitimacy; but the question was decided between them by Teti or Thoth and the gods. From O., after his death, and Isis sprung Harpocrates. See HARPOCRATES. O. seems to have been finally revived, and to have become the judge of the Karmeter or Hades, presiding at the final judgment of souls in the Hall of the two Truths, with the 42 demons who presided over the capital sins, and awarding to the soul its final destiny. Thoth or Hermes recorded the judgment, and justified the deceased against his accusers, as he had formerly done for Osiris.

Considerable diversity of opinion existed amongst the ancients themselves as to the meaning of the myth of Osiris. He represented, according to Plutarch, the inundation of the Nile; Isis, the irrigated land; Horus, the vapours; Buto, the marshes; Nephthys, the edge of the desert; Anubis, the barren soil; Typhon, was the sea; the conspirators, the drought; the chest, the river's banks. The Tanaitic branch was the one which overflowed unprofitably; the 28 years, the number of cubits which the Nile rose at Elephantine; Harpocrates, the first shootings of the corn. Such are the naturalistic interpretations of Plutarch; but there appears in it the dualistic principle of good and evil, represented by O. and Set or Typhon, or again paralleled by the contest of Ra or the Sun, and Apophis or Darkness. The difficulty of interpretation increased from the form of O. having become blended or identified with that of other deities, especially Ptah-Socharis, the pigmy of Memphis, and the bull Hapis or Apis, the avatar of Ptah. Osiris was the head of a tetrad of deities, whose local worship was at Abydos, but who were the last repetition of the gods of the other nomes of Egypt, and who had assumed an heroic or mortal type. In form, O. is always represented swathed or mummied in allusion to his embalmment; a net-work, suggestive of the net by which his remains were fished out of the Nile, covers this dress; on his head he wears the cap *af*, having at each side the feather of truth, of which he was the lord. This is placed on the

horus of a goat. His hands hold the crook and whip, to indicate his governing and directing power; and his feet are based on the cubit of truth; a panther's skin on a pole is often placed before him, and festoons of grapes hang over his shrine, connecting him with Dionysos. As 'the good being,' or Onnophris the meek hearted, the celestial or king of heaven, he wears the white or upper crown. Another and rarer type of him represents him as the *Tat*, or emblem of stability, wearing the crown of the two Truths upon his head. His worship, at a later time, was extended over Asia Minor, Greece, and Rome, and at an early age had penetrated into Phœnicia, traces of it being found on the coins of Malta and other places. He became introduced along with the Isiac worship into Rome, and had votaries under the Roman empire. But the attacks of the philosophers, and the rise of Christianity, overthrew these exotic deities, who were never popular with the more cultivated portion of the Roman world.

Herodotus, ii. 40–42; Plutarch, *De Iside*; Tibullus, i. 7; Diodorus, i. 25; Prichard, *Mythology*, p. 208; Wilkinson, *Man. and Cust.* iv. 314; Bunsen, *Egypt's Place*, i. 414.

O'SMAZOME, a name given by Thenard to the spirit-extract of flesh, on which, as he supposed, its agreeable taste, when cooked, depended. The term is now abandoned by chemists.

O'SMIUM (symb. Os; old equiv. 100; new eq. 200; spec. grav. 10) is one of the noble metals which occurs in association with platinum in the form of an alloy with iridium. It may be obtained in the metallic condition by several processes which yield it either in thin, dark-gray glistening scales, or as a dense iron-black mass. It is the least fusible of all the metals; the oxyhydrogen jet volatilising, but not fusing it.

Five oxides of O. are known—viz., the *protoxide* (OsO), which is of a dark-green colour, and forms green salts when dissolved in acids; the *sesquioxide* (Os₂O₃), which has not been isolated; the *binocide* (OsO₂), which is black; the *teroxide* (OsO₃), which possesses the characters of a weak acid, but has not been isolated; and *osmic acid* (OsO₄), which occurs in colourless, glistening, acicular crystals, freely soluble in water, and very volatile. At about 220°, this compound gives off an extremely irritating and irrespirable vapour; and hence the name of the metal (from the Greek word *osmē*, odour). It produces a permanent black stain upon the skin, and gives a blue precipitate with tincture of galls. O. also forms four chlorides, which correspond in composition to the first four oxides. This metal was discovered by Tennant in 1803.

O'SMOSE; DIALYSIS. The earlier discoveries of Dutrochet and Graham have been briefly described in the article on DIFFUSION (q. v.). The subject has, however, been much extended recently, principally by the investigations of Graham; and as the whole phenomena are exceedingly interesting and important, since secretion, absorption, and various other organic processes are to a great extent dependent on them, some further detail, especially of these later facts, may here be given.

When two different liquids are separated by a bladder or other membrane, or a piece of calico coated with coagulated albumen, there is always a more or less rapid transference of the two liquids in opposite directions through the diaphragm. In certain cases, the explanation given in the article referred to is complete, but in others it appears to be insufficient. Graham has made an extensive series of experiments upon osmose, where distilled

water was on one side of the diaphragm, and various liquids and solutions on the other, and has arrived at many general results, of which the following are the more important. The osmose is considered as *positive* when more of the water passes through the diaphragm than of the other liquid. Such substances as gum, gelatine, &c., produce scarcely any effect. Solutions of neutral salts, such as common salt, Epsom salts, &c., follow the ordinary law of diffusion, as if no diaphragm had been interposed. Acid salts in solution, and dilute acids, pass rapidly into the water—or the osmose is *negative*; while alkaline solutions give, in general, a strong *positive* effect.

In all the cases in which an osmotic action occurs which cannot be explained by capillary forces, there is chemical action on the diaphragm; and conversely, such osmose cannot be produced if the material of the diaphragm be not acted on by the liquids in contact with it.

But the most remarkable results of Graham's later investigations are those relating to Dialysis—i. e., to the separation of the constituents of mixtures, and even the decomposition of chemical compounds, by osmose. The results of his earlier investigations, above given, shew a remarkable difference between two classes of bodies; gum, gelatine, &c., which form viscous solutions, on the one hand; and salts, acids, and alkalies, on the other. The first class he has called *Colloids*; the second, *Crystalloids*. The former are extremely sluggish, the latter comparatively rapid in their action. Thus, of common salt and albumen, under precisely similar circumstances, there pass through the diaphragm in a given time quantities which are as 25 to 1 by weight. Hence, if a solution containing both classes of substances be opposed to pure water, the crystalloids will pass rapidly through the diaphragm, and the colloids slowly. This process promises to be of very great value in medical jurisprudence, as, without introducing any new substance (except the diaphragm and distilled water), we have the means of separating from the generally colloidal contents of animal viscera such poisonous crystalloids as white arsenic, vegetable alkaloids, &c., which by the old methods was in general attended with great difficulty, and often uncertainty. These methods are still in their infancy, but enough is already known to shew how valuable they must soon become to the chemist and the toxicologist. One economical application has been proposed, and shewn to be practicable. When a bladder is filled with the brine of salt beef, and suspended in fresh water, the salt after a time nearly all disappears, and there remains in the bladder a rich extract of meat fit for making soup.

For a brief notice of the speculations which Graham's researches have led him to form as to the nature of *Matter*, we refer to the article on that subject.

OSMUNDA, a genus of Ferns, distinguished by spore-cases in branched, stalked masses. The **OSMUND-ROYAL**, **ROYAL**, or **FLOWERING FERN** (*O. regalis*), is the noblest and most striking of British ferns. It is very frequent in the districts of Scotland and Ireland most remarkable for the moisture of their climate, growing in boggy places and the wet margins of woods. It has bipinnate fronds, and panicle spore-cases upon altered fronds, which appear as stalks distinct from the fronds, and assimilate the general appearance to that of a phanerogamous plant. It sometimes rises to 11 feet in height. It is found in many parts of Europe, and in North America. It possesses tonic and styptic properties, and its root-stocks were formerly

employed in scrofula. The root-stocks abound in a mucilaginous substance, which, being extracted by

Royal Fern (*Osmunda regalis*):

a, pinnate of a barren frond; b, branchlet of fertile frond; c, spore-case; d, the same, shewing how it opens by two valves.

boiling them in water, is used in the north of Europe instead of starch.

OSNABRÜCK, or **OSNABURG**, a territory occupying the western portion of the Prussian province of Hanover, and embracing the principality of O., the countships of Lingen and of Bentheim, and the duchy of Arensburg-Meppen and the lordship of Papenburg. Area, 2403 square miles; pop. (1880) about 290,135.

OSNABRÜCK, the chief town of the territory, lies in the midst of the extended and fruitful valley of the Hase, 80 miles west-south-west of Hanover by railway. It still ranks as one of the principal commercial cities of Hanover, although it cannot boast of the pre-eminence which it enjoyed before the establishment of the Zollverein. Pop. (1880) 32,812. O. has thriving manufactories of cigars and tobacco, paper-hangings, and cotton and woollen goods, and extensive works for the preparation of mineral dyes and cement, besides iron, machinery, and carriage manufactories. According to the opinion of antiquarians, O. stands on the site of the ancient Wittakindsburg, which was raised to a bishopric in 783 by Charlemagne, some relics of whom, together with the pretended bones of the martyrs Crispinus and Crispinianus, are preserved in the cathedral—a fine specimen of the Byzantine style of architecture of the 12th century. The Church of St Mary, a noble Gothic building, was erected by the burghers of O. in the 14th c. during their contentions with their haughty ecclesiastical rulers, and contains the grave of Möser, in whose honour a statue was placed in the square of the cathedral in 1836. The signing of the peace of Westphalia in 1648, in an apartment of the town-hall, is commemorated by the preservation of the portraits of all the ambassadors who took part in the treaty. It was decreed in this treaty that the ancient bishopric of O. should thenceforth be occupied alternately by a Roman Catholic prelate and a Protestant secular prince of the House of Brunswick-Lüneburg; and after having been last held by Frederick, Duke of York, the district of O. was ceded to Hanover in 1803, and the chapter finally dissolved.

O'SPREY (*Pandion*), a genus of *Falconidae*, of which only one species is known (*P. haliaetus*), also called the **FISHING HAWK** or **FISHING EAGLE**, and sometimes the **BALD BUZZARD**. It is singular among the *Falconidae* in preying *exclusively* on fish; and to this its whole structure and habits are adapted. Its whole length is about twenty-two inches: it is of a dark-brown colour, variegated with black, gray, and white. The under parts are white, except a light-brown band across the chest.

Osprey (*Pandion haliaetus*).

The bill is short, strong, rounded, and broad. The tail is rather long, the wings are very long, extending beyond the tail; the under surface of the toes remarkably rough, covered with small pointed scales, suited for the securing of slippery prey; the claws not grooved beneath, as in most of the *Falconidae*. The feathers are destitute of the supplementary plume, which is considerably developed in most of the *Falconidae*. The intestine differs from that of the other *Falconidae* in being very slender and of great length.

The O. is chiefly to be seen near the sea, lakes, and large rivers. No bird is more widely diffused; it is found in all quarters of the world; its geographical range including Europe, Asia, Africa, North and South America, and Australia, and both very warm and very cold climates. It is everywhere a bird of passage, retiring from high northern latitudes on the appearance of frost. It occurs on many parts of the British coasts, and is sometimes found in inland districts, but is nowhere abundant in Britain. In some places in Scotland, it still breeds year after year, on the highest summit of a ruined building, or the top of an old tree. It is very plentiful in some parts of North America; and its return in the beginning of spring is hailed with joy by fishermen, as indicative of the appearance of fish. The nest is a huge structure of rotten sticks, in the outer interstices of which smaller birds sometimes make their nests; for the O. never preys on birds, and is not dreaded by them. It is, indeed, of a pacific and timorous disposition, and readily abandons its prey to the White-headed Eagle (or Erne, q. v.). In the days of falconry, the O., being very docile, was sometimes trained and used for catching fish.

O'SSA, the ancient name of a mountain on the east side of Thessaly, near Pelion, and separated from Olympus by the vale of Tempe. It is now called Kissavo. The conical summit is covered

with snow during the greater part of the year. The ancients placed the seat of the Centaurs and Giants in the neighbourhood of Pelion and Ossa.

O'SSEIN. This term is applied by chemists to the substance in the tissue of the bones which yields gluten. It is obtained by the prolonged action of dilute hydrochloric acid on bone, which dissolves all the earthy matter. The material thus procured retains the form of the bone without its hardness, and must be repeatedly washed with water, and treated with alcohol and ether to remove traces of salts, fat, &c. It is insoluble in water, but is converted into gluten (one of the forms of gelatine) by the action of boiling water—a transformation which is much facilitated if a little acid be present. The ossein yielded by different kinds of animals requires different times for its conversion into gluten; and that of young animals changes more rapidly than that of adults of the same species. It appears to exist in the bones in a state of freedom—that is to say, not in combination with any of the salts of lime. Fremy's analyses shew that the amount of gluten is precisely the same as that of the ossein which yields it, and that the two substances are isomeric.

O'SSIAN, POEMS OF. Ossian, or Oisín (a word which is interpreted the 'little fawn'), a Celtic warrior-poet, is said to have lived in the 3d c., and to have been the son of Fingal or Finn MacCumhail. The poems which are ascribed to him in manuscripts of any antiquity, are few and short, and of no remarkable merit. But in 1760—1763, a Highland schoolmaster, James Macpherson (q. v.), published two epics, *Fingal* and *Temora*, and several smaller pieces and fragments, which he affirmed to be translations into English prose of Gaelic poems written by O., and preserved by oral tradition in the Scottish Highlands. Their success was wonderful. They were received with admiration in almost every country of Europe, and were translated not only into French and Italian, but into Danish and Polish. But their authenticity was challenged almost as soon as they saw the light, and a long and angry controversy followed. That they were what they claimed to be, was maintained by Dr Blair, Lord Kames, the poet Gray, and Sir John Sinclair. That they were more or less the fabrication of Macpherson himself, was maintained by Dr Johnson, David Hume, Malcolm Laing, and John Pinkerton. While this controversy still raged, another sprang up scarcely less angry or protracted. Macpherson made O. a Scotch Highlander, but the Irish claimed him as an Irishman. The fact is he was both: for in those early times, the north-east of Ireland and the west coast of Scotland were practically one country; the people spoke one language, they were of one blood; and the narrow strip of sea that divided them served not as a wall of separation, but rather as an easy passage of communication by means of boats. As to the real authorship of the poems, as the original manuscripts which Macpherson used have never been produced, there will always remain doubts; one thing only we know, that he did use materials of the same nature as the Ossianic traditions that may be picked up from the mouth of the people in many parts of Ireland and the Highlands at the present day; but how far under Macpherson's hands they were remodelled remains a secret. The recent contribution to this question made by J. F. Campbell in his *Leabhar na Feinne*—a digest of all the Ossianic ballads either published by others or collected by Mr Campbell himself—has not tended much to clear up the matter. No trace of Macpherson's two large poems has been recovered. On one point all Gaelic scholars

seem agreed—that Macpherson did not, and could not have written the Gaelic. Poems ascribed to O., committed to writing in the Highlands in the first half of the 16th c., are printed in the *Dean of Lismore's Book* (Edin. 1862), with translations into English and into modern Gaelic. The poems ascribed to O., preserved in Ireland, were published by the Ossianic Society in six volumes (Dublin, 1854—1861). Students of the Ossianic poems will find much assistance from consulting the edition of the Gaelic with a new translation by Dr Clerk of Kilmallie (Edin. 1870). In 1876 the O. controversy was again agitated, but came to nothing.

OSSIFICATION, or the formation of bone, is a process to which physiologists have paid much attention, but regarding which there is still considerable difference of opinion. On one point, however, there is a general agreement—viz., that the bones are not in any instance a primary formation, but always result from the transformation and earthy impregnation of some pre-existing tissue, which is most commonly either cartilage or a membrane containing cell-nuclei. At a very early period of embryonic life, as soon, indeed, as any structural differences can be detected, the material from which the bones are to be formed becomes mapped out as a soft gelatinous substance, which may be distinguished from the other tissues by being rather less transparent, and soon becoming decidedly opaque. From this beginning the bones are formed in two ways: either the tissue just described becomes converted into cartilage, which is afterwards replaced by bone, or a germinal membrane is formed, in which the ossifying process takes place. The latter is the most simple and rapid mode of forming bone. When ossification commences, the membrane becomes more opaque, and exhibits a decided fibrous character, the fibres being arranged more or less in a reticulated manner. These fibres become more distinct and granular from impregnation with lime salts, and are converted into incipient bone, while the cells which are scattered among them shoot out into the bone corpuscles, from which the canaliculi are extended probably by resorption. The facial and cranial bones, with the exception of those at the base of the skull, are thus formed without the intervention of any cartilage.

The process of ossification in Cartilage (q. v.) is too complex and difficult to follow in these pages. Some physiologists hold that when ossification is carried on in cartilage, a complete molecular replacement of one substance by the other takes place; while others believe that more or less of the cartilaginous matrix remains, and becomes impregnated with earthy matter, at the same time that gluten is substituted for chondrine (chondrine being the variety of gelatine that is yielded by ossein or bone-cartilage before ossification, while gluten is yielded after that process is established). All the bones of the body, excepting those of the head and face already mentioned, are at first formed, in part at all events, from cartilage.

The time at which ossification commences does not at all follow the order in which the primordial cartilage is laid down. Thus the cartilage of the vertebrae appears before there is any trace of that of the clavicle, yet at birth the ossification of the latter is almost complete, while that of the former is very imperfect for many years. We will briefly trace the process of ossification as it occurs in the human femur or thigh-bone. Ossification commences in the interior of the cartilage at determinate points, which are hence termed *points* or *centres of ossification*. From these points the process advances into the surrounding substance. In the second month of fetal life, one of these centres shews itself

about the middle of the shaft, and from this point ossification rapidly extends upwards and downwards along the whole length of the shaft. The upper and lower ends remain cartilaginous, and it is not till the last month of fetal life that a second centre appears at the lower end. The third centre, from which the upper end of the bone is ossified, does not appear till about a year after birth. The bone now consists of two extremities or *epiphyses*, with an intermediate shaft or *diaphysis*; and the superior epiphysis is not ossified to the shaft until about the eighteenth, and the inferior until after the twentieth year. At about the fifth year, a fourth ossific centre is developed in the cartilage of the greater trochanter, and a fifth centre appears in the lesser trochanter at about the fourteenth year. These osseous processes, thus developed from special ossific centres, are termed *apophyses*. Most of the long bones are developed in a corresponding way. It is a curious fact (which is of such general occurrence that it may be regarded as a law) that in the skeletons both of man and of the lower animals, the union of the various apophyses to the epiphyses, and of the epiphyses to the diaphysis or shaft, takes place in the inverse order to that in which their ossification began. The advantages derived from this subdivision of the long bones into segments, with interposed cartilaginous plates, are obvious. Besides the greater facilities for growth thus afforded, the flexibility of the bony framework is thereby greatly increased, and its escape from injury during the many falls incidental to this period of life is in no small degree attributable to this cause. See Humphry *On the Human Skeleton*, pp. 33—45.

True Ossification sometimes occurs as a morbid process; but in many cases, the term is incorrectly used (especially in the case of blood-vessels) to designate a hard calcareous deposit, in which the characteristic microscopic appearances of true bone are altogether absent.

In one sense, the osseous tissue that is formed in regeneration of destroyed or fractured bones, may be regarded as due to a morbid, although a restorative action. Hypertrophy of bone is by no means rare, being sometimes local, forming a protuberance on the external surface, in which case it is termed an *exostosis*; and sometimes extending over the whole bone or over several bones, giving rise to the condition known as *hyperostosis*. Again, true osseous tissue occasionally occurs in parts in which, in the normal condition, no bone existed, as in the dura mater, in the so-called permanent cartilages (as those of the larynx, ribs, &c.), in the tendons of certain muscles, and in certain tumours. The peculiar causes of the osseous formations which are unconnected with bone, are not known.

Calcareous deposits or concretions not exhibiting the microscopical character of bone, but often falsely termed ossifications, are of no unfrequent occurrence. Analyses of such concretions occurring in pus, in the valves of the heart, in the muscles, and in the lungs, are given by Vogel in his *Pathological Anatomy of the Human Body*; and in some of these concretions, the phosphate and carbonate of lime occur in nearly the same percentages as those in which they are found in bone. The diseased condition usually but incorrectly called ossification of the arteries, is of sufficient importance to require a brief notice. In consequence of the deposition of earthy or calcareous matter in the middle coat of the artery, the vessel loses all its elasticity, and becomes a rigid, unyielding tube. All parts of the arterial system are liable to this change; but it is more frequently met with in the ascending portion and arch of the aorta, than in any other part of

that vessel, and is more common in the lower extremities than the upper. The affection is usually partial, but occasionally it appears to be almost universal. Thus, Dr Adams has recorded a case, in the Dublin Hospital Reports, in which no pulsation could be felt in any part of the body, and even the heart offered no other sign of action than a slight undulating sound. Old age strongly predisposes to this diseased condition, and probably few very aged persons are altogether exempt from it. There is also reason to believe that gout and rheumatism favour these calcareous deposits. This condition of the arteries may give rise to aneurism, to gangrene of the extremities in aged persons, and to atrophy, and consequent feebleness of the brain and heart. (The coronary arteries, which supply the heart with the arterial blood necessary for its own nutrition, are very often, although not always, ossified in angina pectoris.) Moreover, this condition of the vessels very materially increases the risk from severe accidents and surgical operations.

OSTADÉ, ADRIAN VAN, a celebrated painter and engraver of the Dutch school, was born at Haarlem, as has lately been proved, in 1610. His teachers were Franz Hals and Rembrandt. He followed his art at Haarlem, till the French army of Louis XIV. threatened Holland, when he removed to Amsterdam, where he spent the remainder of his life. He died in 1685. Country dancing-grounds, farm-yards, stables, the interiors of rustic hovels and beer-shops, are the places which he loves to paint; and his persons are for the most part coarse peasant carls, drunken tobacco-smokers, or peasant women employed in country work. In everything he did there is a bright and vivid naturalness. Not equal to Teniers in originality and quiet humour, he surpasses him in the force and fineness of his execution, though he is not free from triviality and repetitions, and inaccuracies in drawing. He was a prolific painter, and his works are to be found in all the museums and collections of the Netherlands, Germany, France, and England. They have been well engraved by Vischer, Suyderoef, and himself.—ISAAC VAN OSTADÉ, brother of Adrian, also a painter, was born at Haarlem in 1621, and died at Amsterdam in 1649. He did not equal his brother, whose style he laboured to imitate.

OSTASHKO'FF, a manufacturing district town of Great Russia, in the government of Tver, stands on the south-east shore of Lake Seliger; lat. 57° 10' N., long. 33° 6' E. The first settlements on this site are said to have taken place in 1230. Pop. (1890) 12,000. Skin-dressing, boot-making, and fishing in the neighbouring lakes are the principal employments of the inhabitants. The woods in the vicinity furnish bark for tanning purposes, and charcoal for the blacksmiths' shops. There are in O. about 40 tanyards, in which skins are dressed, and Russian leather prepared to the amount of £90,000 annually. The leather prepared at Savine's tanyard is known in England, Austria, Italy, and North America. 280,000 pairs of boots are made annually, and 400 men and 1000 women are engaged in the manufacture. Manufactures of hatchets and scythes are also carried on. The commerce of O. is small, however, owing to its remote distance from important lines of communication.

OSTENDE, a strongly fortified town of the Belgian province of West Flanders, on the German Ocean, at the opening of the Ostende and Bruges Canal, and on the state railway. Pop. (1881) 19,696. Notwithstanding its proximity to the sea,

the shallowness of the harbour prevents large ships from entering the port except at high tide. It ranks, however, as the second seaport of the kingdom, Antwerp being the first, and is fortified with walls and broad ditches. It has some good manufactories for linens, sailcloths, and tobacco, and several sugar, salt, and candle works. From its position as a station for the steamers plying daily between London, Dover, and the continent, and as the terminus of various branches of railway in connection with the great French and German lines, it is a lively and active place of transport traffic, and is resorted to in the summer as a bathing-place by 12,000 persons from all parts of the continent. It is, moreover, an important station for oyster, cod, and herring fishing; has a good naval school, some ship-yards, an efficient staff of pilots, and is the seat of a commercial tribunal and a chamber of customs. Its imports in 1873 amounted to 16,000,000 francs; its exports to 15,000,000 francs. The harbour is furnished with a light-house, and is provided with an admirably-constructed stone promenade for the accommodation of the public. O. is memorable for the protracted siege which it underwent from 1601 to 1604, terminating in the surrender of the Dutch and Flemish garrison to the Spanish commander, Spinola.

OSTEOCOLA, a kind of size or glue made by removing the mineral matter from bones, and dissolving the gelatine. Its common name is bone-glue.

OSTEOLEPIS (Gr. bone-scale), a genus of fossil ganoid fish peculiar to the Old Red Sandstone. It is

Osteolepis.

separated from its allies by having the two anal and two dorsal fins alternating with each other. Seven species have been described.

OSTEOLOGY (Gr. *ostea*, the bones) is that department of anatomy which treats of the chemical and physical properties of the osseous tissue, and of the shape, development and growth, articulations, &c., of the various bones of which the skeleton is composed. See BONE, OSSIFICATION, SKELETON, &c.

OSTERO'DÉ, a small town of Hanover, in the principality of Grubenhagen, situated at the western base of the Harz Mountains, on the Söse, an affluent of the Leine, 20 miles north-east of Göttingen. It contains large grain stores, from which the miners of the neighbourhood and their families are supplied with grain at a low and fixed rate. Cotton, woollen, and linen fabrics and hosiery are extensively manufactured, also lead and copper. Pop. (1880) 6087.

O'STIA, a city of Latium, at the mouth of the Tiber, about 16 miles from Rome. It is said to have been founded by Ancus Martius, and was regarded as the oldest Roman colony. It first acquired importance from its salt-works, the establishment of which is attributed to Ancus Martius, and afterwards as the port where the Sicilian, Sardinian, and African corn shipped for Rome was landed; yet its name first occurs during the second Punic war. It was long, too, the principal station of the Roman navy; but its harbour was exceedingly bad, and gradually the entrance became silted up with alluvial deposits, so that vessels could no longer approach

it, but were compelled to ride at anchor in the open roadstead, and to disembark their cargoes there. At length the Emperor Claudius dug a new harbour or basin two miles north of O., and connected it with the Tiber by a canal. It was named the *Portus Augusti*, and around it soon sprung up a new town called *Portus Ostiensis*, *Portus Urbis*, *Portus Roma*, and often simply *Portus*. Yet it was not till nearly the close of the Roman empire that the prosperity of O. as a city began to decline. Its decay, however, was rapid, and in the 8th c. it was a mere ruin. During the middle ages, a village—the modern O.—was built about half a mile above the ancient one; but it has not more than 100 permanent inhabitants, who still carry on the manufacture of salt, established in the pre-historic times of ancient Rome. The ruins of O. extend for a mile and a half along the banks of the Tiber, and are nearly a mile in breadth.

OSTRACION, a genus, and **OSTRACIONIDÆ**, a family of fishes of the order *Plectognathi*. They are remarkably distinguished by having the whole body covered with an inflexible tuberculated coat of mail, formed of six-sided bony scales or plates combined in a tessellated quincuncial manner; the fleshy lips, the fins, and the tail protruding through holes in the armour. The gill-opening appears in the armour as a mere slit, bordered with a skinny edge, but there is a true gill-cover within. There are no ventral fins. The vertebrae are generally coalescent. There is little muscular substance, and in some species it is reputed poisonous; but the liver is large, and yields much oil. Some of the species are known by the names of **TRUNK-FISH** and **COFFER-FISH**. They are mostly found in the Indian and American seas. None are British.

O'STRACISM, a right exercised by the people of Athens of banishing for a time any person whose services, rank, or wealth appeared to be dangerous to the liberty of his fellow-citizens, or inconsistent with their political equality. It was not a punishment for any particular crime, but rather, as has been observed, a precautionary measure to remove such leaders as were obviously exercising a dangerous ascendancy in the state. Ostracism was introduced by Cleisthenes about the beginning of the 6th c. B.C., after the expulsion of the Peisistratids. The people were annually asked by the Prytanes if they wished to exercise this right, and if they did, a public assembly was held, and each citizen had opportunity of depositing, in a place appointed for the purpose, a potsherd (*ostrakon*) or small earthen tablet, on which was written the name of the person for whose banishment he voted. Six thousand votes were necessary for the banishment of any person; but the greatest men of Athens—Miltiades, Themistocles, Cimon, Alcibiades, &c.—were subjected to this treatment. The banishment was at first for ten years, but the period was afterwards restricted to five. Property and civil rights or honours remained unaffected by it. Alcibiades succeeded in obtaining the final abolition of ostracism, of which, however, Plutarch and Aristotle speak as a necessary political expedient, and its utility has been very ably defended in modern times by Mr Grote (*History of Greece*, vol. iv. pp. 200 *et seq.*).

O'STRICH (*Struthio*), a genus of birds of the order *Gallatores*, and tribe *Brevipennes* (q. v.), in Cuvier's system—the order *Cursores* (or Runners) of some ornithologists. In this genus the bill is of moderate length, broad, flattened, rounded at the tip, the mandibles flexible; the head small; the neck long; the legs long (both tibia and tarsus) and very robust, the lower part of the tibia, as well as

the tarsus, naked; the feet have only two toes, of which the inner is the largest, and has a short claw, the outer has no claw; the wings are too short to be used for flight, but are useful to aid in running; the plumage is lax and flexible; the wings and tail have long soft drooping plumes. Only one species is known (*S. camelus*), a native of the sandy deserts of Africa and Arabia; the South American ostriches, or *Nandus* (q. v.), constituting a distinct genus. The O. is the largest of all birds now existing, being from six to eight feet in height to the top of its head, and an adult male weighing from two to three hundred pounds. The male is rather larger than the female. The head and upper part of the neck are scantily covered with a thin down, through which the skin is visible. The young have the

Ostrich (*Struthio camelus*).

head and neck clothed with feathers. The general plumage is glossy black in the adult male, dark gray in the female and young, with a slight sprinkling of white feathers; the long plumes of the wings and tail are white, occasionally marked with black. On each wing are two plumeless shafts, not unlike porcupine's quills. The inner toe is very large, about seven inches long, and its claw hoof-like. Whilst the sternum is destitute of a keel, and the muscles which move the wings are comparatively weak, those which move the legs are of prodigious strength, so that the O. is not only capable of running with great speed, but of striking such a blow with its foot as to make it too formidable for the leopard and other large beasts of prey to assail it. It has been often known to rip open a dog by a single stroke, and a man is recorded to have suffered the same fate. The eyes of the O. are large, and the lids are furnished with lashes. Its sight is keen, so that it descries objects at a great distance in the open desert.

The O. shuns the presence of man, but is often to be seen in near proximity to herds of zebras, quaggas, giraffes, antelopes, and other quadrupeds. It is gregarious, although the flocks of ostriches are not generally very large. It is polygamous, one male usually appropriating to himself, when he can, from two to seven females, which seem to make their nest in common, scooping a mere hole in the sand for this purpose. Each female is supposed to lay about ten eggs. The eggs are all placed on end in the nest, which often contains a large number, whilst around it eggs are generally to be found scattered on the sand. Concerning these, it has been supposed that they are intended for the food of the young birds before they are able to go in quest of other food; an improbable notion, not supported by evidence. It seems at least as likely that these scattered eggs are laid by females waiting whilst the nest is occupied by another, and that they are lost to the ostriches, and no more

regarded. Contrary to a very generally received opinion, the O. does not leave her eggs to be hatched entirely by the heat of the sun; nor is it the case, as has been alleged, that the male only incubates. Both parents give their assistance in the task of watching the eggs. ¶The male and female sit alternately on the eggs for six weeks; the cock sitting all the night, but the female helping in the daytime.

The O. feeds exclusively on vegetable substances, its food consisting in great part of grasses and their seeds; so that its visits are much dreaded by the cultivators of the soil in the vicinity of its haunts, a flock of ostriches soon making terrible devastation of a field of corn. The O. has a very large crop, a strong gizzard, and a pretty large *proventriculus* between the crop and the gizzard: the intestines are voluminous, and the coeca long, with a remarkable spiral valve. There is a receptacle in which the urine accumulates, as in a bladder, a thing very uncommon in birds.

The O. swallows large stones, as small birds swallow grains of sand, to aid the gizzard in the trituration of the food; and in confinement, has often been known to swallow very indiscriminately whatever came in the way, pieces of iron, bricks, glass, old shoes, copper coins, &c. Its instincts do not suffice to prevent it from swallowing very unsuitable things; copper coins were fatal in one instance, and a piece of a parasol in another.

The O. is very patient of thirst, or is capable of subsisting for a long time without water. It often supplies the want of water by eating the gourds or melons of the desert, to which even the lion is said to resort on the same account.

The speed of the O., when it first sets out, is supposed to be not less than 60 miles an hour; but it does not seem to be capable of keeping up this speed for a long time. It is successfully hunted by men on horseback, who take advantage of its habit of running in a curve, instead of a straight line, so that the hunter knows how to proceed in order to meet it and get within shot. It is often killed in South Africa by men who envelop themselves in ostrich skins, and admirably imitating the manners of the O., approach it near enough for their purpose, without exciting its alarm, and sometimes kill one after another with their poisoned arrows.

The strength of the O. is such that it can easily carry two men on its back.

The voice of the O. is deep and hollow, not easily distinguished, except by a practised ear, from the roar of the lion. It also more frequently makes a kind of cackling; and when enraged and striking violently at an adversary, hisses very loudly.

The flesh of the O. is not unpalatable when it is young, but rank and tough when old. It is generally believed to have been prohibited as unclean to the Jews (Lev. xi. 16), although the name is translated *owl* in the English Bible. There are frequent references to it in the Old Testament.

The eggs of the O. are much esteemed as an article of food by the rude natives of Africa, and are acceptable even to European travellers and colonists. Each egg weighs about three pounds, and is thus equal to about two dozen ordinary hen's eggs. The egg is usually dressed by being set upright on a fire, and stirred about with a forked stick, inserted through a hole in the upper end. The thick and strong shell is applied to many uses, but particularly is much employed by the South African tribes for water-vessels. The reader will probably recollect the interesting plate in Livingstone's *Travels* of women filling ostrich shells with water. In taking ostrich eggs from the nest, the South African is careful not to touch any with the

hand, but uses a long stick to draw them out, that the birds may not detect the smell of the intruder, in which case they would forsake the nest; whilst otherwise, they will return, and lay more eggs.

The long plumes of the O. have been highly valued for ornamental purposes from very early times, and continue to be a considerable article of commerce. See FEATHERS; also OSTRICH-FARMING in SUPP., Vol. X.

The O. is often to be seen in Britain in confinement, and readily becomes quite tame and familiar, although still apt to be violent towards strangers. Great numbers were exhibited in the public spectacles by some of the Roman emperors; and the brains of many ostriches were sometimes presented in a single dish, as at the table of Helio-gabalus.

OSTRICH FEATHERS are occasionally borne as a heraldic charge, and always represented drooping. Three white ostrich feathers are the well-known badge of the Prince of Wales. According to common tradition, they were assumed in consequence of Edward the Black Prince having plucked a plume of ostrich feathers from the casque of John of Luxemburg, king of Bohemia, who fell by his hand at Crecy. There is, however, no doubt that ostrich feathers were previous to that time a cognizance of the Plantagenets. Prince Henry, eldest son of James I., first established the present arrangement of the three ostrich feathers within a prince's coronet.

OSTROG, a small district town of West Russia, in the government of Volhynia, 100 miles west of Jitomir. Here, in the reign of Constantine of Ostrog, a school and typography were established, and the first Slavonic Bible printed in 1558. Pop. 7700.

O'STROGOTHS. See GOTHES.

OSUNA, a town of Spain in the province of Seville, and 48 miles east-south-east of the city of that name, stands in a fertile plain, and on a triangular hill crowned by a castle and the collegiate church. It stands in the midst of a highly fertile plain, productive in grain, olives, almonds, &c. An extensive panoramic view is obtained from the castle. The collegiate church, in the mixed Gothic and cinque-cento style, was built in 1534. It was pillaged by Sout of 5 cwt. of ancient church plate, and was converted by him into a citadel and magazine. Pop. 17,500, who are engaged in agriculture and in the manufacture of linen goods, and iron and earthenware.

OSWEGO, a city and port of entry, in New York, U.S., is situated at the mouth of Oswego River, on Lake Ontario, at the extremity of the Oswego Canal, a branch of the Erie, and is a station on several railways. It is a handsome city, with streets 100 feet wide, crossing at right angles, with costly government buildings, custom-house, court-house, post-office, city hall, hospital, orphan asylum, library, 16 churches, 2 daily and 2 weekly newspapers, excellent schools, &c. It has a large trade with the lake country and Canada, and exports about 12,000,000 dollars per annum. On the river are 14 flour-mills, making 600,000 barrels of flour a day, with 11 elevators for unloading vessels for 45,000 bushels an hour. Among the manufactures is that of 13,000,000 lbs. of what is known as Oswego flour, made from Indian corn. The lumber received in 1874 measured 210,814,573 feet, besides 47,605,053 shingles, 2,654,126 pieces of heading, &c. There are a fort and a navy-yard, and an excellent harbour recently constructed. Pop. (1870) 20,910; (1880) 21,117.

OSWEGO TEA, a name given to several species of *Monarda*, particularly *M. purpurea*, *M. didyma*,

and *M. kalmiana*, natives of North America, because of the occasional use of an infusion of the dried leaves as a beverage. They belong to the natural order *Labiata*, somewhat resemble mints in appearance, and have an agreeable odour. The infusion is said to be useful in intermittents, and as a stomachic. Some other species of *Monarda* are used in the same way.

OSWESTRY, a thriving market town and municipal borough of England, in the county of Salop, 18 miles north-west of Shrewsbury. The stone pillars of its ancient gateways still stand in the streets. There are also scanty remains of a castle, said to have been the ancestral seat of Walter Fitzalan, progenitor of the royal House of Stuart, who, during the troubles of the reign of King Stephen, fled hence to Scotland, and became steward to David I., king of Scotland. O. is the centre of an extensive agricultural district; it has extensive market-places, and its weekly market for agricultural produce and cattle is very largely attended. There are corn mills and coal-mines in the vicinity. O. contains the offices and works of the Cambrian Company, and is favourably situated as a railway centre. Pop. (1881) of municipal borough, 7851. O. is said to derive its name from Oswald, king of Northumbria, slain here in 642. Near the town is Oswald's Well, a fine spring of water; and 'Old O,' an ancient encampment.

OSYMA'NDYAS, the name of a great king of Egypt, mentioned by Diodorus and Strabo, who reigned, according to these authors, as the 27th successor of Sesostria. He distinguished himself, according to these authors, by his victories, and invaded Asia with an army of 400,000 men and 20,000 cavalry, and conquered the Bactrians, who had been rendered tributary to Egypt by Sesostria. In honour of this exploit, he is said by Hecateus to have erected a monument which was at once a palace and a tomb, and which, under the name of *Osymandeion*, was renowned for its size and splendour in later times. It was said to be situated in the necropolis of Thebes, or at Gournah, and close to the sepulchres of the concubines of the god Amen Ra. The *Osymandeion* is generally believed to be represented by the extant ruins of the palace of Rameses III. at Medinet Haboo, though great difficulty has been felt in reconciling the descriptions of its magnificence in ancient writers with the dimensions of the modern relic; and Letronne, in his *Tombeau d'Osymandias* (Par. 1831), has even ventured to suppose that it was an imaginary edifice invented by the Greeks from their acquaintance with the great palaces of Thebes, but this scepticism is considered extreme. The name of O. is difficult to recognise amongst the Egyptian kings, the nearest approach to it being one of the Setis, either the 1st or 2d, called after death, Asiri-Menepthah. Others consider O. the Ismendes of Strabo, or the Mendes of Herodotus. The name of Amenophis may also lie concealed in his name, so much ambiguity pervades the subject.

Diodorus, i. 46 to 50; Strabo, xvii. p. 8, 11—16; Juvenal, xv. 38; Letronne, *Mem. de l'Inst.* ix. p. 321; Champollion, *Lettres Ecrites*, p. 260, 303; Champollion-Figeac, *L'Egypte*, 69, 291, 313—315.

OTAGO, one of the most recent settlements, but, at the same time, the most prosperous, populous, and likely to become the most influential 'provincial district' of New Zealand. Since the reincorporation of Southland—a portion of its territory which, in 1861, was parted from O. and raised into a small separate province, an experiment which failed in a short time—it is now the most southern province of South Island (see NEW ZEALAND). O. is bounded

on the north by the province of Canterbury, and on the west, east, and south by the Pacific Ocean; is in length 200 miles, 160 miles in breadth, and possesses an invaluable line of coast which measures 400 miles. The entire area is about 15,500,000 acres—over 24,000 square miles. Pop. in 1871, 69,500; in 1881 it had increased to 135,418. The chief rivers are the Waitaki, the Clutha, and the Mataura, all of which flow south-south-east, and are navigable to a greater or less extent. The western regions of O. remain unsurveyed, but are known to be covered with high, and in many cases snow-capped mountains, stretching along the whole line of coast, and extending inland for upwards of 60 miles. East and north-east from the Mataura River to the shore the surface is well known, and consists of mountain-ranges alternating with valleys, and extending parallel to the sea and to each other as far inland as the valley of the Manuherikia, one of the first affluents of the Clutha. The climate of O. is exceedingly healthy and invigorating; frost and snow are unknown except in the higher ranges, and rain, though sufficiently abundant to answer the demands of agriculture, does not interfere with outdoor occupations. All the English fruits and flowers, with some trifling exceptions, are grown here to perfection. The northern and interior districts of the province are eminently adapted, as regards both soil and climate, for agriculture as well as cattle-breeding. The western districts are rugged, and covered with forests; but in the eastern regions are many fertile and well-watered tracts, admirably suited for the production of corn, and the rearing of cattle and sheep. In mineral wealth the province of O. is remarkably rich. Coal, iron, copper, silver, lead, &c., have been found, and useful earths and clays are abundant. Gold has been found in small quantities in other provinces of New Zealand, as in Auckland and Nelson Province; but by far the most important gold-fields of the colony are in the province of Otago. Gold was first discovered here by Mr Gabriel Read in June 1861, in a gully, since called Gabriel's Gully, on the Tuapeka, an affluent of the Clutha, in a direct line 37 miles west of Dunedin. Read placed his discovery in the hands of government, and was presented by the Provincial Council with £500 as a reward. In less than two months from the discovery of gold, 3000 people were at work in the Tuapeka valley, and were obtaining 6000 oz. a week. From this time gold-mining became a staple employment. A 'rush' was made from Australia; Dunedin, formerly the village-capital of the province, now rapidly increased in size and trade, new fields were discovered, and the immigration-lists were immensely swelled. From June 1861 to June 1863, 700,000 oz., worth nearly £3,000,000, were obtained. The most productive gold-field hitherto discovered is the Arrow River District, in the vicinity of Lake Wakatipu. This district was made known in November 1862, and from that time to the end of October 1863, 237,655 oz.—value £956,620—were forwarded to Dunedin by escort. The value of the gold exported from O. up to the middle of 1880 was £15,818,943. In 1880 the total exports were valued at £1,989,901, and the imports at £1,988,101. Gold, wool, timber, and agricultural produce are the principal articles of export. In agriculture, the chief growths are wheat, oats, barley, potatoes, and hay. In 1880 there were 53,771 acres in wheat, 143,165 in oats, 10,114 in barley, 5290 in potatoes, 111,278 in grass. In 1875 the figures were: Wheat, 23,116 acres, supplying 980,128 bushels; oats, 80,788 acres, 3,018,148 bushels; barley, 5055 acres, 163,437 bushels; potatoes, 3342 acres, 18,420 tons; hay, 7592 acres, 11,899 tons. The first

band of settlers reached the shores of O. in the spring of 1848. The capital is Dunedin (q. v.). The population of this city and its suburbs and various boroughs was, in 1881, 42,802. O. was originally a class colony connected with the Free Church of Scotland; but the influx of immigrants consequent on the discovery of gold has obliterated its distinctive character.

OTAHEITE. See TAHITI.

OTALGIA (Gr. *ot-*, the ear, and *algos*, pain) is neuralgia of the ear. It occurs in fits of excruciating pain, shooting over the head and face, but it is not accompanied by fever, nor usually by any sensation of throbbing. Its causes and treatment are those of neuralgia generally, but it is particularly caused by caries of the teeth, which should always be carefully examined by a dentist in these cases. When patients complain of *earache*, the pain is far more commonly due to *otitis*, or inflammation of the tympanic portion of the ear, a much more serious affection.

O'TARY (*Otaria*), a genus of the Seal family (*Phocidae*), distinguished from the rest of the family by a projecting auricle or auditory conch (often popularly called 'external ear'), and by a very remarkable character, a double cutting edge in the four middle upper incisors. The membrane which unites the toes of the hind-feet is prolonged into a flap beyond each toe. The fore-legs, as if intended exclusively for swimming, are placed further back in the body than in the true seals, giving the otaries the appearance of having a longer neck. The hind-legs are more like the fore-legs than in the true seals.—The **SEA LION** (*O. jubata* or *O. Stelleri*) of the northern seas is about 15 feet in

Sea Lion (*Otaria jubata*), female and calf.

length, and weighs about 16 cwt. It inhabits the eastern shores of Kamtschatka, the Kurile Islands, &c., and is in some places extremely abundant. It is partially migratory, removing from its most northern quarters on the approach of winter. It is to be found chiefly on rocky coasts and islet rocks, on the ledges of which it climbs, and its roaring is sometimes useful in warning sailors of danger. It is much addicted to roaring, which, as much as the mane of the old males, has obtained for it the name of sea lion. The head of this animal is large; the eyes very large; the eyebrows bushy; the hide thick; the hair coarse, and reddish; a heavy mass of stiff, curly, crisp hair on the neck and shoulders. The old males have a fierce aspect, yet they flee in great precipitation from man; but if driven to extremities, they fight furiously. Sea lions are capable of being tamed, and become very familiar with man. They are polygamous, but a male generally appropriates to himself only two or

three females. They feed on fish and the smaller seals.—The sea lion of the southern seas, once supposed to be the same, is now generally believed to be a distinct species, and, indeed, more than one species are supposed to inhabit the southern seas.—The **URSINE SEAL**, **URSINE O.**, or **SEA BEAR** (*O. ursina*), is an inhabitant of the Northern Pacific. It is scarcely 8 feet long. The hinder limbs being better developed than in most of the seals, it can stand and walk almost like a land quadruped. The muzzle is prominent, the mouth small, the lips tumid, the whiskers long; the tip of the tongue is bifurcated, the eyes are large, the skin is thick, the hair long, erect, and thick, with a soft underclothing of wool. The food consists of sea otters, small seals, and fish. The ursine seal is polygamous, a strong male appropriating to himself from eight to fifty females. It swims with great swiftness. It is fierce and courageous. Its skin is much prized for clothing in the regions in which it abounds. As in the case of the sea lion, it is doubtful if the geographical range of the sea bear extends to the southern seas, or if it is represented there by a similar species. Several other species of *O.* are inhabitants of the Pacific and Southern Oceans. The **FUR SEAL** (*O. Falklandica*) is one of these. It is found on the Falkland Islands, South Shetland, &c. It is of a long and slender form, with broad head, and clothed with soft, compact, grayish-brown hair, amongst which is a very soft, brownish fur. It is gregarious and polygamous. When South Shetland was first visited, its seals had no apprehension of danger, and unsuspectingly remained whilst their fellows were slain and skinned; but they have since learned to be upon their guard. The skin of the fur seal is in great demand, chiefly for ladies' mantles, and was much used for making a kind of soft fur cap, which was very common thirty or forty years ago.

OTCHAKOV, a small town and seaport of South Russia, in the government of Kherson, surrounded on all sides by a barren steppe, stands at the western extremity, and on the north shore, of the estuary of the Dnieper, 40 miles east-north-east of Odessa. It traces its foundation to the very earliest times, and is supposed by some to be the spot where stood the Grecian colony Olbia; by others, to be Tomi, the scene of Ovid's banishment. At the end of the 15th c., the khan of the Crimea built here a strong fortress. Its present name occurs, for the first time, in 1557. During the Russian wars with Turkey in the 18th c., O. was alternately the property of each, until it was taken by Potemkin in 1788, and definitively annexed to the Russian dominions. The vicinity of Odessa is fatal to the development of foreign commerce at its port. Pop. (1877) 5140, the greater part of whom are Jews, and are employed in salting fish for transport to Little Russia.

OTHMANN IBN AFFAN, third calif of the Moslems, was born about 574. He belonged to the family of the prophet, and was cousin-german of Abu Sofian. One of the early converts to Islam, he was one of its most zealous supporters, and linked himself still more strongly to Mohammed by becoming his son-in-law and private secretary. He was elected to succeed Omar in the califate in December 644, and a most unworthy successor he proved to be. The Moslem empire, however, continued to extend itself on all sides till the insane nepotism of O. gave its progress a sudden check. The able and energetic leaders who had been appointed by Omar were superseded by members of his own family, and of that of Abu Sofian; and the consequences were what might have been

expected. Egypt revolted, and the calif was compelled to reinstate Amru in the government of that country, and several other rebellions were only quelled by a similar restoration of the previous governors. Zealous Moslems deeply deplored the folly of their chief, and were indignant at seeing the chair of the prophet occupied by O., while Abu-bekr, and even Omar, were accustomed to seat themselves two steps below it. Emboldened by the knowledge of his vacillating and cowardly disposition, they showered upon him reproaches and menaces; but the bearer of their remonstrances having been bastinadoed by O.'s order, a general revolt ensued. O. averted the crisis by unconditional submission; but having soon after attempted to put to death Mohammed, the son of the Calif Abu-bekr, the latter made his appearance at Medina at the head of a troop of malcontents, and forcing his way to the presence of O., stabbed him to the heart. O. was of a mild and pacific disposition, but he was at the same time most ambitious of power, though after his accession to supreme authority, he shewed himself to be, either from age or natural imbecility, deplorably deficient in those energetic virtues, without which the control of a warlike people and the management of a mighty empire such as that of the Moslems, were utterly impossible. O. was the first to cause an authentic copy of the Koran to be composed.

OTHMAN, OTHOMAN, or OSMAN I., surnamed *Al-ghazi* ('the conqueror'), the founder of the Turkish power, was born in Bithynia in 1259. His father, Orthogrul, the chief of a small tribe of Ogtuzian Turks, had entered the service of Alla-din Kaikobad, the Seljuk sultan of Iconium, and had rendered important services to that monarch and his successors in their wars with the Byzantines and Mongols. Orthogrul dying in 1289, after a rule of more than half a century, his tribe chose his son Osman (i.e., the 'young bustard,') as his successor. O. trod in his father's footsteps; and on the destruction of the sultanate of Iconium in 1299 by the Mongols, succeeded in obtaining possession of a portion of Bithynia. He had previously subjugated many of the neighbouring Ogtuzian chiefs, and this new accession of territory rendered him powerful enough to attack the Byzantines with success. In July 1299, he forced the passes of Olympus, and took possession of the whole territory of Nicaea, with the sole exception of the town of that name, which resisted his efforts for five years longer. In 1301, he defeated the Emperor Andronicus II. at Baphaeon; in 1307, he incorporated the province of Marmara in his dominions; and continued till his death, in 1326, steadily to pursue his plans of conquest. 'Othman,' says Knolles, 'was wise, politic, valiant, and fortunate, but full of dissimulation, and ambitious above measure; not rash in his attempts, and yet very resolute; to all men he was bountiful and liberal, especially to his men of war and to the poor. Of a poor lordship, he left a great kingdom (Phrygia, Bithynia, and the neighbouring districts), having subdued a great part of Asia Minor, and is worthily accounted the first founder of the Turks' great kingdom and empire.' O. assumed the title of sultan (though this is denied by many historians) on the extinction of the Iconium sultanate in 1299, held his court at Kara-Hissar, and struck money in his own name. From him are derived the terms Ottomans, Othomans, and Osmanli or Osmanlı, which are employed as synonymous with Turks. See OTTOMAN EMPIRE.

OTHO, MARCUS SALVIUS, Roman emperor, was descended of an ancient Etruscan family, and was born 32 A.D. He was a favourite companion of

Nero, who appointed him governor of Lusitania, in which office he acquitted himself creditably. On the revolt of Galba against Nero, O. joined himself to the former; but being disappointed in his hope of being proclaimed Galba's successor, he marched at the head of a small band of soldiers to the forum, where he was proclaimed emperor, and Galba was slain, 69 A.D. O. was recognised as emperor over all the Roman possessions, with the exception of Germany, where a large army was stationed under Vitellius. The first few weeks of his reign were marked by an indulgence towards his personal enemies, and a devotion to business, which, though at total variance with his usual habits, excited in the minds of his subjects the most favourable hopes. But the tide of rebellion raised in Germany by Valens and Cæcina during the reign of Galba had by this time gathered strength, and these commanders having prevailed upon Vitellius, who had become a mere good-humoured glutton, to join his forces to theirs, the combined army poured into Italy. O. fortunately possessed several able generals, who repeatedly defeated the rebels; but the prudence of some among them in restraining the enthusiasm of their troops, who wished further to follow up their victories, was unfortunately considered as cowardice or treason, and produced dissensions in O.'s camp. This state of matters becoming known to the generals of Vitellius, encouraged them to unite their armies, and fall upon the forces of Otho. An obstinate engagement took place near the junction of the Adda and the Po, in which the army of O. was completely routed, and the relics of it went over on the following day to the side of the victor. O., though by no means reduced to extremity, resolved to make no further resistance; settled his affairs with the utmost deliberation; and then stabbed himself, on the 15th of April 69 A.D.

OTHO I., or the Great, son of the Emperor Henry I. of Germany, was born in 912, and after having been early recognised as his successor, was, on the death of his father in 936, formally crowned king of the Germans. His reign was one succession of eventful and generally triumphant wars, in the course of which he brought many turbulent tribes under subjection, acquired and maintained almost supreme power in Italy, where he imposed laws with equal success on the kings of Lombardy and the popes at Rome, consolidated the disjointed power of the German emperors, and established Christianity at many different points in the Scandinavian and Slavonic lands, which lay beyond the circuit of his own jurisdiction. His earliest achievement was a successful war against the Bohemian Duke Boleslas, whom he reduced to subjection, and forcibly converted to Christianity; next, the Dukes of Bavaria and Franconia were compelled to succumb to his power; the former paying the penalty of his opposition to O. by defeat and death in battle, and the latter by the confiscation of his territories, which, together with the other lapsed and recovered fiefs of the empire, were bestowed on near and devoted relatives of the conqueror. After subduing the Slavi of the Oder and Spree, for whose Christian regeneration he founded the bishoprics of Havelburg and Brandenburg, driving the Danes beyond the Eyder, compelling their defeated king to return to the Christian faith and do homage to himself; and after founding, at the suggestion of his mother's former chaplain, Adeldag, the bishoprics of Aarhuus, Ribe, and Slesvig, which he decreed were for ever to be free from all burdens and imposts, he turned his attention to the affairs of Italy. Here he presented himself as the champion of the beautiful Adelaide, the widow of the murdered King Lothaire; and having defeated her importunate suitor, Berengar II. (q.v.),

married her, and assumed supreme power over the north of Italy in 951. The wars to which this measure gave rise, obliged O. frequently to cross the Alps; but at length, after a great victory gained over the Huns in 955, and the defeat and capture of Berengar, O. was acknowledged king of Italy by a diet held at Milan; and after being crowned with the iron crown of Lombardy, was, in 962, recognised by Pope John XII. as the successor of Charlemagne, and crowned Emperor of the West at Rome. O. lost no time in asserting his imperial prerogatives; and having called a council, effected the deposition of John, whose licentiousness had become a burden to Italy and a scandal to Christendom, and caused Leo VIII. to be elected in his place. Fresh wars were the result of this step. Popes and anti-popes distracted the peace of Rome; but through all these disorders, O. maintained the supremacy which he claimed as Emperor of the West, in regard to the election of popes and the temporal concerns of the Roman territories. His later years were disturbed by domestic differences; for his elder son, Ludolph, and his son-in-law, Konrad of Lorraine, having risen in rebellion against him, through jealousy of his younger son and intended successor, Otho, the empire was distracted by civil war. Although the war terminated in the defeat of the rebels, and the recognition of young Otho as king of the Germans, and his coronation at Rome, in 967, as joint-emperor with his father, O.'s favourite scheme of uniting the richly-dowried Greek princess, Theophania, with the young prince, met with such contempt from the Greek emperor, that his outraged pride soon again plunged him into war. His inroads into Apulia and Calabria, however, proved convincing arguments in favour of the marriage, and Theophania became the wife of young Otho, with Calabria and Apulia for her dowry. O. died at Minsleben, in Thuringia, in 973, and was buried at Magdeburg, leaving the character of a great and just ruler, who had extended the limits of the empire, and restored the prestige of the imperial power more nearly to the stand which it occupied under Charlemagne than any other emperor. He created the duchy of Carinthia, and the markgraftoms of East and North Saxony; appointed counts-palatine; founded cities and bishoprics; and did good service to the empire, in reorganising the shaken foundations of its power in Europe. See *Vehse's Leben Kaiser O.'s des Grossen* (Dresd. 1827).

OTHO II., surnamed *Rufus*, 'the Red,' son of Otho I., was born in 955, and succeeded his father in 973. For a time, O. was content to rule under the regency of his mother, the Empress Adelheid; but differences having arisen between them, through the headstrong and ambitious inclinations of the young monarch, his mother withdrew from all share in the administration, and left him to the exercise of his own will, which soon brought him into collision with the great vassals of the crown. Civil war broke out under the leadership of Henry II. of Bavaria, who formed a secret alliance against the young emperor with Harald, king of Denmark, and Micalav of Poland, and for a time fortune inclined to the side of the rebels; but O.'s astuteness circumvented their designs, and after defeating Henry, and depriving him of his duchy, he marched against the Danish king, who had been making successful incursions into Saxony. O.'s first attack on the Dannevirke having proved of no avail, he retired, vowing that he would return before another year, and force every Dane to forswear paganism. O. kept his promise, returning to the attack the following year, when, according to the old chroniclers, acting by the advice of his ally, Olaf Trygvesson of

Norway, he caused large quantities of trees, brushwood, and stubble to be piled up against the Dannevirke, and set on fire, and this drove away the defenders, and destroyed their fortifications. The defeated Harold was soon overpowered by the superior numbers of the Germans, and compelled to receive baptism, as the badge of his defeat. The next scene of war was Lorraine, which the French king, Lothaire, had seized as a former appanage of his crown; but here, after a partial defeat, O. succeeded in reasserting his power; and not content with this advantage, devastated Champagne, pursued and captured Lothaire, and advanced upon Paris, one of the suburbs of which he burned. Scarcely was this war ended, when the disturbed condition of Italy called O. across the Alps. His presence put a stop to the insurrection at Milan and Rome, where he re-established order; and having advanced into Lower Italy, he defeated the Saracens, drove back the Greeks, and having re-established his supremacy in Apulia and Calabria, which he claimed in right of his wife, Theophania, made himself master of Naples and Salerno, and finally of Tarentum, in 982. The Greek emperor, alarmed at the successful ambition of O., called the Saracens again into Italy, who gave him battle with overwhelming numbers. The result was the total defeat of the emperor, who only escaped from the hands of the victors by plunging with his horse into the sea, and swimming, at the risk of his life, to a ship. Unluckily, it was a Greek ship, and O. was virtually a prisoner; but as the vessel neared Rossano, a friendly port, he contrived to escape by a cunning stratagem. O. now hastened to Verona, where a diet was held, which was numerously attended by the princes of Germany and Italy, and at which his infant son, Otho, was recognised as his successor. This diet is chiefly memorable for the confirmation by O. of the franchises and privileges of the republic of Venice, and the enactment of many new laws, which were added to the celebrated Longobard code. O.'s death at Rome, at the close of the same year, 983, arrested the execution of the vast preparations against the Greeks and Saracens, which had been planned at the diet of Verona, and left the empire embroiled in wars and internal disturbances. See Giesebrecht's *Jahrbücher des Deutschen Reichs unter der Herrschaft, Kaiser O.'s II.* (Berl. 1840).

OTHO III., who was only three years old at his father's death, was at once crowned king of the Germans at Aix-la-Chapelle in 983, from which period till 996, when he received the imperial crown at Rome, the government was administered with extraordinary skill and discretion by three female relatives of the boy-king—viz., his mother, Theophania; his grandmother, Adelheid; and his aunt, Matilda, Abbess of Quedlingburg, who, in conjunction with the learned Willegis, Archbishop of Mainz, directed his education. The princes of the imperial family disputed the right of these royal ladies to the custody of the young king; and Henry of Bavaria, the nearest agnate, having seized the person of O., tried to usurp the supreme power; but opposed by the majority of the other princes of the empire, he was compelled to release him, in consideration of receiving back his forfeited duchy. O. early shewed that he had inherited the great qualities of his forefathers, and when scarcely fifteen years of age, at the head of his army, defeated the troops of the patrician Crescentius, the self-styled consul of Rome, and thus restored order in the Roman territories. In 996, he was crowned emperor by his relative, Gregory V.; and having settled the affairs of Italy returned to Germany, where he defeated the Slaves, who had long carried on war against the empire;

and having forced Miciav, Duke of Poland, to do him homage, he subsequently raised the Polish territories to the rank of a kingdom, in favour of Miciav's successor, Boleslas. The renewed rebellion of Crescentius, who drove Gregory from the papal throne, compelled O. to return to Italy, where success, as usual, attended his measures. Crescentius, who had thrown himself into St Angelo, was seized and beheaded, together with twelve of his chief adherents; the anti-pope, John XVI., imprisoned; Gregory restored; and on the speedy death of the latter, O.'s old tutor, Gherbert, Archbishop of Ravenna, raised to the papacy under the title of Sylvester II. O., elated with his success, took up his residence in Rome, where he organised the government, erected new buildings, and shewed every disposition, notwithstanding the ill-concealed dissatisfaction of the Romans, to convert their city into the capital of the western empire. The near approach of the year 1000, to which so many alarming prophecies were then believed to point as the end of the world, induced O. to undertake a pilgrimage to the Holy Land, where he founded an archbishopric. On his return, after visiting Charlemagne's grave at Aix-la-Chapelle, and removing the consecrated cross, suspended from the emperor's neck, he again repaired to Rome, to consolidate his schemes of establishing a Roman empire. The insurrection of the Romans frustrated his plans, and escaping from Rome at the risk of his life, he withdrew to Ravenna, to await the arrival of powerful reinforcements from Germany; but before they had crossed the Alps, O. died in 1002, at the age of 22, apparently from poison, which was said to have been administered to him by the widow of Crescentius, who, it is said, had deliberately set herself to win his affections that she might have an opportunity of avenging the death of her husband; and with him the male branch of the Saxon imperial House became extinct. See Wilman's *Jahrbücher des Deutschen Reichs unter Kaiser Otto III.* (Berl. 1840).

OTHO I., second son of Ludwig, king of Bavaria, was born at Salzburg, 1st June 1815, and on the erection of Greece into a kingdom in 1832, was appointed by the protecting powers king of Greece. Till he attained his majority, the government was intrusted to a regency, which was unable to suppress internal disorder, or counteract the diplomatic intrigues of foreign powers. On assuming the government in 1835, O. transferred the court from Nauplia to Athens, and passed into law several important measures, which afforded the most lively satisfaction to his subjects. During a visit to Germany in 1836, he married the Princess Amalie of Oldenburg. A monetary crisis, provoked partly by false administrative measures, and partly by too prompt demands for repayment on the part of the protecting powers, threw the affairs of Greece into confusion, and materially weakened the king's popularity. A national reaction against the Germanising tendencies of the court followed, and resulted in 1843 in a military revolution, which was suppressed. O. now attempted to soothe the general discontent by taking the oath to the new constitution of March 30, 1844, but his efforts were only partially successful. Though the Bavarian ministers were dismissed, the king and his Greek advisers shewed the most reactionary tendencies, and attempted in various ways to curtail the privileges which the new constitution had conferred on the people. The equivocal position in which he was placed, in 1853, between the allied powers on the one hand, and his subjects, whose sympathies were strongly in favour of Russia, on the other, greatly increased the difficulties of his situation. The occupation of the Piræus by Anglo-French

troops enabled him to restrain the enthusiasm of his subjects; but after their withdrawal in 1857, he was obliged to adopt severe measures against the frontier brigands. His council, too, was composed of men unable or unwilling to support him, and his position became year by year more and more difficult. The strong pro-Russianism of the queen rendered her for some time a favourite; but the belief that O.'s absolute measures were due to her instigation, turned the tide of popular hatred so strongly against her, that attempts were made on her life. The general discontent at last found vent in insurrections at Nauplia and Syra in 1862, which were soon suppressed. A more formidable insurrection in the districts of Missolonghi, Acarnania, Elis, and Messenia, having for its object the expulsion of the reigning dynasty, broke out in October of the same year, and in a few days extended to the whole of Greece. O. and his queen fled to Salamis, from which place he issued a proclamation declaring that he quitted Greece to avoid the effusion of blood, and a provisional government was then established. This government, in February 1863, resigned its executive power to the National Assembly, which confirmed its acts, and decreed that Prince Alfred of England had been duly elected king of Greece. On the refusal of this prince to accept the throne, their choice fell on Prince William of Slesvig-Holstein-Sonderburg-Glücksburg, the second son of Christian IX., king of Denmark, who, under the title of George I., King of the Hellenes, in September 1863, assumed the functions of royalty. O. died July 26, 1867.

OTITIS, or inflammation of the tympanic cavity of the ear, may be either acute or chronic, and it may come on during the course of certain febrile affections, especially scarlatina, or in consequence of a scrofulous, rheumatic, or gouty constitution; or it may be excited by direct causes, as exposure to currents of cold air, violent syringing or probing, &c. The symptoms of the acute form are sudden and intense pain in the ear, increased by coughing, sneezing, or swallowing, *tinnitus aurium*, or singing or buzzing noises heard by the patient, and more or less deafness. If the disease goes on unchecked, suppuration takes place, and the membrane of the tympanum ulcerates, and allows of the discharge of pus, or inflammation of the dura mater and abscesses in the brain may be established. In less severe cases there is usually a considerable amount of persistent damage, and an obstinate discharge of matter (*otorrhæa*) is a frequent sequence of the disease.

The treatment of so serious an affection must be left solely in the hands of the medical practitioner.

The symptoms of the chronic and less acute varieties of otitis are unfortunately so slight, that they are often neglected, until the patient finds the sense of hearing in one or both ears almost completely gone. In these milder forms of otitis, the general indications of treatment are to combat the diathesis on which they frequently depend, and to improve the general health. Very small doses of mercury continued for a considerable time (such as one grain of gray powder night and morning), and small blisters occasionally applied to the nape of the neck or to the mastoid process, are often of service in very chronic cases. If there is any discharge, the ear should be gently syringed once or twice a day with warm water, after which a tepid solution of sulphate of zinc (one grain to an ounce of water) may be dropped into the meatus, and allowed to remain there two or three minutes.

O'TLEY, a small market town of England, in the West Riding of Yorkshire, on the right bank of

the Wharfe, 29 miles west-south-west of York. Its parish church was built in 1507. Extensive cattle and grain markets are held here. Worsteds spinning and weaving, machine-making, and the manufacture of malt, bricks, and leather, are the main occupations. Pop. (1871) 5855; (1881) 6803.

OTORRHEA signifies a purulent or mucopurulent discharge from the external ear. It may be due to various causes, of which the most frequent is catarrhal inflammation of the lining membrane of the meatus, and the next in frequency is Otitis (q. v.) in its various forms. If the discharge is very fetid, a weak solution of chloride of lime, or of Condy's Disinfectant Fluid, may be used, in place of the solution of sulphate of zinc recommended in article OTITIS; and in obstinate cases of catarrhal inflammation of the lining membrane, the discharge may often be checked by pencilling the whole interior of the meatus with a solution of five grains of nitrate of silver in an ounce of water.

OTRANTO, **TERRA DI**, now called **LECCE**, the extreme south-eastern province of Italy, forming the heel of the Italian boot, is bounded on the N. W. by the provinces of Bari and Basilicata, and surrounded on all other sides by the sea. Area, 3293 sq. m.; pop. (1881) 553,298. It occupies the ancient Iapygian or Messapian peninsula, and is 102 miles in length, and from 25 to 35 miles in breadth. Three parts of its surface are covered with hills, offsets from the Apennines of Basilicata. All the rivers are short, many of them being lost in the marshes of the interior; but abundant springs and heavy dews render the soil surprisingly fertile. Good pasture-lands and dense forests occur. The climate is pleasant and healthy, except along the shores, both on the east and west coasts, and in the vicinity of the marshes, which in summer generate malaria. An abundance of the best wine, with corn and olive-oil, are produced; tobacco (the best grown in Italy), cotton, and figs, almonds, oranges, &c., are also produced. The capital is Lecce (q. v.).

OTRANTO (the ancient *Hydruntum*), a small town on the south-east coast of the province of the same name, 24 miles south-east of Lecce. During the latter period of the Roman empire, and all through the middle ages, it was the chief port of Italy on the Adriatic, whence passengers took ship for Greece—having in this respect supplanted the famous Brundisium of earlier times. In 1480, it was taken by the Turks, and at that time it was a flourishing city of 20,000 inhabitants; but it has long been in a decaying condition, principally on account of malaria. O. possesses a castle and a cathedral. Its harbour is unsafe. In clear weather, the coast of Albania is visible from Otranto. Pop. about 2000.

OTTAWA, one of the largest rivers of British North America, rises in lat. 48° 30' N., long. 76° W., in the watershed on the opposite side of which rise the St Maurice and Saguenay. After a course of above 600 miles, it falls into the St Lawrence by two mouths, which form the island of Montreal; and the entire region, drained by it and its tributaries is estimated at 80,000 square miles. During its course it sometimes contracts to 40 or 50 yards; elsewhere it widens into numerous lakes of considerable size. It is fed by many important tributaries, such as the Mattawa, Mississippi, Madawasca, and Rideau on the right, the Gatineau and the Rivières du Moine and du Lièvre on the left side. These, with the O. itself, form the means of transit for perhaps the largest lumber-trade in the world, while the clearances of the lumberer have opened the country for several thriving agricultural settlements. The navigation has been greatly improved,

especially for timber, by the construction of dams and slides, to facilitate its passage over falls and rapids. The O. is connected with Lake Ontario at Kingston by the Rideau Canal. Navigation might be made possible from the westward by connecting the O. with Georgian Bay in Lake Huron, through the French River, Lake Nipissing, and the Mattawa. Were this accomplished, it would materially decrease the distance between the east and west.—The O. possesses one of the few literary associations of Canada. At St Ann's, a few miles above its mouth, the house is pointed out where Moore wrote the Canadian Boat-song.

OTTAWA, the capital of the Dominion of Canada, situated 87 miles above the confluence of the Ottawa with the St Lawrence, 126 miles from Montreal, and 450 from New York. It is connected with the Grand Trunk Railway, and stands on the line of the Canadian Pacific Railway. Hull (pop. 7000), on the opposite bank of the river, is incorporated with O. and New Edinburgh, an eastern suburb, is the seat of the Governor-General of Canada. The Rideau Canal divides O.; and the business part of the town, with the chief public buildings, lies to its west side. Originally called Bytown, after Colonel By, who in 1827 was commissioned to construct the Rideau Canal, it was incorporated as a city, and received the name which it now bears in 1854. At the west end of the city, the Ottawa rushes over the magnificent cataract known as the Chaudière Falls; and at the north-east end there are other two cataracts, over which the Rideau tumbles into the Ottawa. The scenery around O. also is scarcely surpassed by any in Canada. The immense water-power at the city is made use of in several saw-mills, which give O. its principal trade, and issue almost incalculable quantities of sawn timber. A suspension-bridge hangs over the Chaudière Falls, connecting Upper and Lower Canada. The city is in communication by steamer on the Ottawa with Montreal; on the Rideau Canal with Lake Ontario at Kingston; and with the principal points of the province by means of the St Lawrence and Ottawa and the Canada Central lines. In three years, 1879 to 1881, the value of total exports varied, from \$1,115,000 to \$2,380,000; and the imports from \$890,000 to \$1,360,000. In 1858, O. was chosen to be the seat of government of the then province of Canada; and in 1860, the Prince of Wales laid the corner-stone of magnificent parliamentary offices. They are among the finest structures on the American continent. Pop. (1871) 21,545; (1881) 27,412. O. returns two members to the House of Commons, and one to the provincial parliament.

OTTER (*Lutra*), a genus of quadrupeds of the Weasel family (*Mustelidae*), differing widely from the rest of the family in their aquatic habits, and in a conformation adapted to these habits, and in some respects approaching to that of seals. The body, which is long and flexible, as in the other *Mustelidae*, is considerably flattened; the head is broad and flat; the eyes are small, and furnished with a *nictitating membrane*; the ears are very small; the legs are short and powerful; the feet, which have each five toes, are completely webbed; the claws are not retractile; the tail is stout and muscular at its base, long, tapering, and horizontally flattened; the dentition is very similar to that of weasels; six incisors and two canine teeth in each jaw, with five molars on each side in the upper, and five or six in the lower jaw; the teeth very strong, and the tubercles of the molars very pointed, an evident adaptation for seizing and holding slippery prey. The tongue is rough, but not so much so as in the weasels. The fur is very smooth, and consists of two kinds of hair—an inner fur very dense and soft,

intermixed with longer, coarser, and glossy hair. The species are numerous, and are found both in warm and cold climates.—The Common O. (*L. vulgaris*) is a well-known British animal, rarer than it once was in most districts, but still found in almost every part of the British Islands, and common also throughout the continent of Europe, and in some parts of Asia. It often attains a weight of 20 to 24 lbs. Its length is fully 2 feet, exclusive of the tail, which is about 16 inches long. The colour is a bright rich brown on the upper parts and the outside of the legs, being the colour of the tips of the long hairs, which are gray at the base; the tips of the hairs in the soft inner fur are also brown, the base whitish-gray; the throat, cheeks, breast, belly, and inner parts of the legs are brownish-gray, sometimes whitish, and individuals sometimes, but rarely, occur with whitish spots over the whole body; the whiskers are very thick and strong; the eyes are black. The O. frequents rivers and lakes, inhabiting some hole in their banks, generally choosing one which already exists, and seldom, if ever, burrowing for itself. It also inhabits the sea-shore in many places, and swims to a considerable distance from the shore in pursuit of prey. Its movements in the water are extremely graceful; it swims with great rapidity in a nearly horizontal position, and turns and dives with wonderful agility. Its prey consists chiefly of fish, and, like the other *Mustelidae*, it seems to take pleasure in pursuing and killing far more than it is able to eat; and in this case it daintily feeds on the choicest part, beginning behind the head of the fish, and leaving the head and often much of the tail part. The O., however, when fish cannot readily be obtained, satisfies the cravings of hunger with other food, even snails and worms, and attacks

O., but considerably larger. The tail is also shorter, and the fur of the belly is almost of the same shining brown colour with that of the back. This species is plentiful in the northern parts of North America. Its skin is a considerable article of commerce, and after being imported into England, is often exported again to the continent of Europe. It is usually taken by a steel-trap, placed at the mouth of its burrow. Its habits are very similar to those of the O. of Europe.—The INDIAN O. (*L. Nair*), has a deep chestnut-coloured fur, and yellowish-white spots above the eyes.—The Brazilian O. (*L. Braziliensis*) is said to be gregarious.—Somewhat different from the true otters is the SEA O. or KALAN (*L. marina*, or *Enhydra lutris*), an animal twice the size of the Common O., a native of Behring's Straits and the neighbouring regions, frequenting sea-washed rocks. There are, at least in the adult, only four incisors in the lower jaw, and the ears are set lower in the head than in the true otters, below, not above, the eyes. The tail is also much shorter. The molar teeth are broad, and well adapted for breaking the shells of molluscs and crustaceans. The hind-feet have a membrane skirting the outside of the exterior toes. The sea O. is much valued for its fur, the general hue of which is a rich black, tinged with brown above, and passing into lighter colours below. The head is sometimes almost white. The skins of sea otters were formerly in very great request in China, so that a price of from £35 to £50 could be obtained for each; but the attention of European traders and hunters having been directed to them—in consequence chiefly of a passage in *Cook's Voyages*—they were carried to China in such numbers as greatly to reduce the price.

O'TTERBURN, BATTLE OF. See CHEVY CHASE.
OTTO or ATTAR OF ROSES. See SUPP., Vol. X.

O'TTOMAN EMPIRE, or 'Empire of the Osmanlis,' comprehends all the countries which are more or less under the authority of the Turkish sultan, and includes, besides Turkey in Asia, and that part of Turkey in Europe which is under his immediate sovereignty, the tributary but autonomous principality of Bulgaria, with the autonomous province of Eastern Roumelia, in Europe (Roumania, Servia, and Montenegro being now independent); Egypt (nominally) and Tripoli, in Africa; and a part of Arabia, including Mecca and Medina, in Asia. The description, topography, and statistics of TURKEY will be found under that head, and this article will consist of a sketch of the origin and history of the Ottoman Empire.

The Ottomans, or Osmanlis, to whom the generic epithet of *Turks* is by common usage now confined, are the descendants of the Oğuzian Turks, a tribe of the great Turkish nation, which in the 13th c. inhabited the steppes east of the Caspian Sea. The tide of Mongol invasion which was then setting in from the north-east, swept the Oğuzes before it, and they, to the number of 50,000, under their chief, Suliman, fled westward to the mountainous region of Armenia. After the chief's death, the majority of the tribe became scattered over Mesopotamia; but a few thousands under Orthoguel, his youngest son, marched westward to aid the Seljuk sultan of Konieh against the Khaurezmians and Mongols, and received from the grateful monarch a grant of land in Phrygia.—His son, OTHMAN (q. v.) (1239—1326), laid the foundation of the independent power of the Turks; and Othman's son and successor, ORKHAN (1326—1359) continued the same aggressive policy, and gained a footing in Europe by the taking of Gallipoli, Koiridicastron, and other

Otter (*Lutra vulgaris*).

small animals of any kind, sometimes making depredations in places far from any considerable stream. The O. produces from two to five young ones at a birth. The flesh of the O. has a rank fishy taste, on which account, perhaps, it is sometimes used in the Roman Catholic Church, as *fish*, by those whose rules forbid them the use of flesh.—O. hunting has long been practised in Britain, although now chiefly confined to Wales and Scotland. Hounds of a particular breed—O. Hounds—are preferred for it.—The O. defends itself with great vigour against assailants. The O. can be easily domesticated, and trained to catch fish for its master. In India, tame otters—probably, however, of another species to be afterwards noticed—are not unfrequently used both for catching fish, which they bring ashore in their teeth, and for driving shoals of fish into nets.—The fur of the O. is in some request, but more on the continent of Europe than in Britain.—The AMERICAN O. or CANADA O. (*L. Canadensis*) is very like the Common

fortresses on the coast. The Greeks, with the usual contempt of civilisation for barbarism, made light of these losses, saying that the Turks had only taken from them a 'hog's sty' and a 'pottle of wine,' in allusion to the magazines and cellars built by Justinian at Gallipoli; but, as the historian Knolles quaintly remarks, 'by taking of such hogsties and pottles of wine, the Turks had gone so far into Thracia, that Amurath, a few years later, placed his royal seat at Adrianople.' Sultan Orkhan, perceiving the advantage of possessing a force trained exclusively for war, organised the body of troops known as Janizaries (q. v.), and to these his successor added the Spahis (q. v.) and the Zanis.—AMURATH I. (1359—1390), the successor of Orkhan, rapidly reduced the Byzantine empire within the limits of Constantinople and some neighbouring districts in Thrace and Bulgaria. A formidable confederacy of the Slavonian tribes of the Upper Danube was formed against him, and, supported by multitudes of warriors from Hungary and Italy, they advanced into Serbia to give him battle; but their army, amounting, it is said, to 500,000 men, was defeated with dreadful slaughter at Kossova (1390); and though the sultan was assassinated on the eve of the battle, his son, BAJAZET I. (q. v.) (1390—1402), followed up this victory by ravaging Serbia and Walachia. Moldavia was also overrun, and a second crusading army, under the king of Hungary, totally routed at Nicopolis (1396); but the defeat and capture of the sultan by Timur (q. v.), gave Constantinople a respite for half a century, by raising up numerous claimants for the Turkish throne; and it was not till 1413 that Bajazet's youngest son, MOHAMMED I. (1413—1422), established his claim to the sceptre. A war which broke out with the Venetian republic at this time produced the most disastrous consequences to the mercantile and maritime interests of the Turks, and internal disorders prevented any aggressions on their neighbours.—AMURATH II. (1422—1450), a prince of considerable ability, completed the conquest of the Greek empire by reducing Macedonia and Greece Proper; and finding that the Hungarians had concluded a secret treaty of offence and defence with the Turkish sultan of Caramania against him, he attacked the former, but was defeated by Hunyady (q. v.), and compelled to retreat. Disheartened at his ill success, he resigned the throne; but on receiving news of a formidable invasion by the army of the papal crusade, resumed the direction of affairs, and totally defeated the invaders, with whom were Hunyady (q. v.) and Scanderbeg (q. v.), at Varna (1444).—MOHAMMED II. (q. v.) (1450—1481), the sworn foe of Christianity, greatly enlarged the Turkish territories. It was he who stormed Constantinople in 1453, and destroyed the last relic of the empire of the Cæsars.—His son, BAJAZET II. (1481—1512), extended his dominions to the present limits of the Turkish empire in Asia and Europe, including, however, also the country to the north of the Black Sea, as far east as the mouth of the Don, portions of Dalmatia, and Otranto in Italy. Bajazet was the first to feel the evil effects of the military organisation of Sultan Orkhan, but all his attempts to get rid of his formidable soldiery were unsuccessful. He attempted the invasion of Egypt, but was totally defeated by the Mameluke sultan at Arbela (1493).—His successors, SELIM I. (q. v.) (1512—1520), and SOLYMAN I. (q. v.), (1520—1566), raised the O. E. to the height of its power and splendour. During their reigns, no ship belonging to a nation hostile to the Turks dared then navigate the Mediterranean, so completely did their fleets command that sea.—SELIM II. (1566—1574), a pacific prince, put an

end to a war with Austria, which had been commenced in the previous reign, by a peace in which it was stipulated that the Emperor Maximilian II. should pay a tribute of 30,000 ducats annually for the possession of Hungary, and that each nation should retain its conquests. During his reign, occurred the first collision of the Turks with the Russians. It had occurred to Selim, that the connection of the Don and Volga by a canal would, by allowing the passage of ships from the Black Sea into the Caspian, be a valuable aid to both military and commercial enterprise, and accordingly he sent 5000 workmen to cut the canal, and an army of 80,000 men to aid and protect them. But, unluckily, the possession of Astrakhan formed part of the programme, and the attack of this town brought down on the Turks the vengeance of the Russians, a people till then unknown in Southern Europe, and the projected canal-scheme was nipped in the bud. The rest of this sultan's reign was occupied in petty wars with Venice, Spain, and his rebellious feudatory of Moldavia.—His son, AMURATH III. (1574—1595), such was then the prestige of the Turks, dictated to the Poles that they should choose as their king, Stephen Bathory, Woiwode of Transylvania; and received the first English embassy to Turkey in 1589, the object of the embassy being to conclude an alliance against Philip II. of Spain. To this the sultan agreed; but the destruction of the Spanish Armada soon after rendered his interference unnecessary. After an exhausting, though successful war with Persia, succeeded a long contest with Austria, in which the Turks at first obtained the most brilliant success, penetrating to within 40 miles of Vienna, but afterwards suffered such terrible reverses, that they were compelled to evacuate all Hungary and Transylvania (hitherto a feudatory), and were only saved from destruction by the Poles, who entered Moldavia, and drove out the Transylvanians and Hungarians, thus affording the Turks an opportunity of rallying, and even recovering some of their losses. The latter part of this war happened during the reign of MOHAMMED III. (1595—1604), and afforded unmistakable symptoms of the decline of Turkish prowess; and a rebellion of the Pasha of Caramania, in Asia, which was quelled not as a Mohammed II. or a Bajazet I. would have quelled it, but by yielding to the pasha's demands, afforded an equally convincing proof of the growing weakness of the central administration, and set an example to all ambitious subjects in future. During the reigns of ACHMET I. (1604—1617), MUSTAFA (1617—1617, 1622—1623), OTHMAN II. (1617—1622), and AMURATH IV. (1623—1640), Turkey was convulsed by internal dissensions, nevertheless, a successful war was waged with Austria for the possession of Hungary; but this success was more than counterbalanced in the East, where Shah Abbas the Great conquered Mesopotamia, Kurdistan, and Armenia; and in the north, where the Poles took possession of some of the frontier fortresses. While Amurath was recovering his lost provinces in the East, the Khan of the Crimea, countenanced by the Poles and Russians, threw off his allegiance. Mustafa, the grand vizier, a man of great ability and integrity, continued to direct the helm of government under IBRAHIM (1640—1649); took from the Poles their conquests; and in a war with the Venetians (1645), obtained Candia and almost all the Venetian strongholds in the Ægean Sea, though with the loss of some towns in Dalmatia.—MOHAMMED IV. (1648—1687) commenced his reign under the most unfavourable auspices; he was only seven years of age, and the whole power was vested in the Janizaries and their partisans, who

used it to accomplish their own ends; but luckily for Turkey, an individual of obscure birth, named Mohammed Köprili, supposed to be of French descent, was, when over seventy years of age, appointed vizier; and the extraordinary talents of this man proved to be the salvation of Turkey at this critical juncture. He was succeeded (1661) in office by his son Achmet, a man of equal ability, and under his guidance the central administration recovered its control over even the most distant provinces; a formidable war with Germany, though unsuccessfully carried on (1663), was concluded by a peace advantageous to the Turks; Crete was wholly subdued, and Podolia wrested from the Poles; though, shortly afterwards, much of this last acquisition was reconquered by John Sobieski (q. v.). Achmet's successor overran the Austrian territories, and laid siege to Vienna; but the siege was raised, and his army defeated, by a combined army under the Duke Charles of Lorraine, and John Sobieski, king of Poland. The Austrians followed up this victory by repossessing themselves of Hungary, inflicting upon the Turks a bloody defeat at Mohacz (1687); but the fortunate appointment of a third Köprili as grand vizier by SOLYMAN II. (1687—1691), was the means of restoring glory and fortune to the Turkish arms.—The reigns of ACHMET II. (1691—1695), and MUSTAFA II. (1695—1702), were occupied with wars against Austria; but with the death of Köprili (1691) fortune deserted the Turks, and the peace of Carlowitz (1699) for ever put an end to Turkish domination in Hungary.—ACHMET III. (1702—1730) was forced by the intrigues of Charles XII. (q. v.) of Sweden, while residing at Bender, into a war with Russia; a step which was immediately followed by an invasion of Moldavia by the Czar Peter. The Czar, imprudently relying on the aid of the Woiwode of Moldavia, found himself in great straits, from which he was rescued by the genius of his queen, afterwards Catharine I. The recovery of the Morea from the Venetians, and the loss of Belgrade and parts of Servia and Walachia, which were, however, recovered during the subsequent reign of MAHMUD I. (1730—1754), and the commencement of a long war with Persia (see NADIR SHAH), were the other prominent occurrences of Achmet's reign. In 1736, the career of Russian aggression commenced with the seizing of Azof, Oczakof, and other important fortresses; but a scheme for the partition of Turkey between Austria and Russia was foiled by the continued series of disgraceful defeats inflicted upon the Austrian armies by the Turks: the Russians, on the other hand, were uniformly successful; but the Czarina becoming very desirous of peace, resigned her conquests in Moldavia, and concluded a treaty at Belgrade. Among the benefits conferred by Sultan Mahmud on his subjects, not the least was the introduction of the art of printing.—His successor, OTTOMAN III. (1754—1757), soon gave place to MUSTAFA III. (1757—1774), under whom the empire enjoyed profound tranquillity; but after his death, the Russians, in violation of the treaty of Belgrade, invaded Moldavia.—The war with Russia continued during the succeeding reign of ABDUL-HAMID (1774—1789); the fortresses on the Danube fell; and the main army of the Turks was totally defeated at Shumla. The campaign was ended 10th July 1774, by the celebrated treaty of Kutschouk-Kainardji. In defiance of its provisions, the Czarina took possession of the Crimea and the whole country eastward to the Caspian. The sultan was compelled, by his indignant subjects, to take up arms in 1787. In 1788, Austria made another foolish attempt to arrange with Russia a partition of Turkey; but, as

before, the Austrian forces were completely routed. The Russians, however, with their usual success, had overrun the northern provinces, taken all the principal fortresses, and captured or destroyed the Turkish fleet.—The accession of SELIM III. (q. v.) (1789—1807) was inaugurated by renewed vigour in the prosecution of the war; but the Austrians had again joined the Russians. Belgrade surrendered to the Austrians, while the Russians took Bucharest, Bender, Akerman, and Ismail (see SUVOROV); but the critical aspect of affairs in Western Europe made it advisable for Russia to terminate the war, and a treaty of peace was accordingly signed at Jassy, 9th January 1792. By this treaty the provisions of that of Kainardji were confirmed; the Dniester was made the boundary-line, the cession of the Crimea and the Kuban was confirmed, and Belgrade was restored to the sultan. Numberless reforms were now projected for the better administration of the empire. The people were, however, hardly prepared for so many changes, and the sultan's projects cost him his throne and life. The occupation of Egypt by the French brought on a war between them and the Turks, in which the latter, by the aid of the British, were successful in regaining their lost territories. In revenge for the defeat of his Egyptian expedition, Napoleon contrived to entrap the sultan into a war with Russia and Britain, which was confined to a struggle in Egypt, in which the British were worsted.—After the ephemeral reign of MUSTAFA IV. (1807—1808), the able and energetic MAHMUD II. (q. v.) (1808—1839) ascended the throne; and though his dominions were curtailed by the loss of Greece, which established its independence, and of the country between the Dniester and the Pruth, which, by the treaty of Bucharest in 1812, was surrendered to Russia, the reformation he effected in all departments of the administration checked the decline of the O. E. Egypt, during his reign, attempted unsuccessfully to throw off the authority of the sultan (see MEHMET ALI, IBRAHIM PASHA).—His son, ABDUL-MEDJID (1839—1861), continued the reforms commenced in the previous reign; but the Czar, thinking that the dissolution of the O. E. was at hand, constantly tried to wring from the sultan some acknowledgment of a right of interference with the internal affairs of the country. It was an attempt of this sort to obtain the exclusive protectorate of the members of the Greek Church in Turkey, that brought on the 'Crimean War' of 1853—1855, in which the Turks were effectively supported by England, France, and Sardinia. The treaty of Paris (1856) restored to Turkey the command of both sides of the lower Danube, excluded the Czar from his assumed protectorate over the Danubian principalities, and closed the Black Sea against all ships of war. The Porte, apparently adopted into the family of European nations, made proclamation of equal civil rights to all the races and creeds of the Turkish dominions. But a massacre of Christians in Lebanon and at Damascus provoked western intervention in 1860.—Abdul-Medjid, whose last years were disgraced by irrational profuseness of expenditure, was succeeded by his brother ABDUL-AZIZ in 1861. Meanwhile the nominally subject peoples of Moldavia and Walachia ventured to unite themselves into the one state of Rumania; and in 1866, the Empire, becoming more and more enfeebled through its corrupt administration, had to look on while the Rumanians expelled their ruler, and, in the hope of securing western support, chose Prince Charles of Hohenzollern to be hereditary prince (*domnu*) of the united principalities. The rebellion of Crete in 1866 threatened a severe

blow to the integrity of the empire, but was ultimately suppressed in 1868—in spite of active help from Greece. Serbia, already autonomous within her own frontiers, demanded the removal of the Turkish garrisons still maintained in certain Servian fortresses; and in 1867 Turkey saw herself compelled to make this concession. In the same year the sultan distinguished the Vali of Egypt by granting to him the unique title of Khedive (q. v.). The vassal king drew down the wrath of his suzerain in 1870 by negotiating directly with foreign courts, and was compelled to give formal tokens of vassalage. But later concessions have made the Khedive virtually an independent sovereign. The Russian government took the opportunity of war between Germany and France to declare, in 1871, that it felt itself no longer bound by that provision of the Paris treaty which forbade Russia to have a fleet in the Black Sea; and a London conference sanctioned this stroke of Russian diplomacy. Between 1854 and 1871 the Turkish debt had increased by more than £116,000,000; and in 1875 the Porte was driven to partial repudiation of its debts. An insurrection in Herzegovina in the latter part of 1874 marked the beginning of a very eventful and critical period in the history of the O. E. The insurrection smouldered on through 1875 and part of 1876, and excited all the neighbouring Slavonic peoples. A threatened revolt in Bulgaria in May 1875 was repressed with much bloodshed; and the merciless cruelty displayed by the Bashi-Bazouks or Turkish irregulars alienated foreign sympathy from the government.—In May Abdul-Aziz was deposed; and his nephew, MURAD V., son of Abdul-Medjid, who succeeded him, was destined in turn to make way for his brother ABDUL-HAMID II. in August of the same year. In June Serbia declared war, and Montenegro followed her example. Before the end of the year the Servians were utterly defeated, in spite of the help of many Russian volunteers; but the state of affairs in the Turkish provinces seemed to call for a conference of the great powers at Constantinople. The proposals then made for the better government of the Christian subjects of Turkey were rejected by the Turkish authorities, who had, during the conference, taken the extraordinary step of bestowing a parliamentary constitution on the O. E. Russia took upon herself to enforce on Turkey the suggestions of the conference, and on 24th April 1877 declared war. Both in Armenia and Bulgaria the opening of the campaign was favourable to Russian arms, but later the Turks rallied and seriously checked the hitherto triumphant progress of the invaders. Even after the Russian forces had been greatly augmented, the Turks resisted energetically. Kara, besieged for several months, resisted till the middle of November; Erzeroum did not surrender until after the armistice had been concluded. Osman Pasha, who established himself in Plevna early in July, repelled with brilliant success repeated and determined assaults from a besieging army of Russians and Rumanians; and he had so strengthened the fortifications as to be able to hold out until the 10th December, when he surrendered. Desperate fighting in the Shipka Pass had failed to expel the Russians from their position in the Balkans; and within a month of the fall of Plevna, the Russians captured the whole Turkish army that was guarding the Shipka Pass, and then easily overran Roumelia. The victorious Muscovites occupied Adrianople in January 1878; on the last day of that month an armistice was concluded; and in March the 'preliminary treaty' of San Stefano was signed. After grave diplomatic difficulties, owing chiefly to the apparent incompatibility of English and Russian interests, a

Congress of the Powers met at Berlin, and sanctioned the cessions and other territorial changes which, with modifications, were carried out between 1878 and 1881. For these, see the article *TURKEY*.

OTWAY, THOMAS, an English dramatist, was born March 3, 1651, at Trotton, near Medhurst, Sussex. He left Oxford without taking a degree, and went to London in search of fortune in 1671. He appeared on the stage, but made a signal failure; and next he applied himself to dramatic composition. In 1675, *Alcibiades*, his first tragedy, was printed; and in the following year he produced *Don Carlos*, a play which was extremely popular, and 'got more money than any preceding modern tragedy.' His first comedy, *Friendship in Fashion*, appeared in 1678, and, being sufficiently immoral to please the taste of the age, met with general appreciation. In 1677 O. received a cornet's commission in a regiment, which, however, was disbanded in 1678, and O. resuming his former occupation, produced the tragedy of *Caius Marius* in 1680. In the same year *The Orphan* met with an extraordinary, and, in some respects, a deserved measure of success. In 1681, *The Soldier of Fortune*, and in the following year, the finest of all his plays, *Venice Preserved*, were produced. From this time till his death, the poet had much to endure from poverty and neglect. Debts accumulating upon him, he retired to an obscure public-house on Tower Hill, for the purpose of avoiding his creditors, and here, at the premature age of 34, he died, April 14, 1685. Although O. achieved a brilliant reputation during his lifetime, although he is described by Dryden as possessing a power of moving the passions which he himself did not possess, and later by Sir Walter Scott as being Shakspeare's equal, if not his superior, in depicting the power of affection; yet his plots are artificial, and his language is without fancy, melody, or polish.

OUDE, or AUDH, a province of British India, separated on the north from Nepal by the lower ranges of the Himalaya, whence it gradually slopes to the Ganges. Extreme length, 270 miles; breadth, 160; area, 23,992 square miles. Formerly an independent chief commissionerhip, it is now administered by the lieutenant-governor of the North-west Provinces. Pop. (1869) 11,220,232; (1881) 11,427,625 (476 to the sq. mile). O. is one great plain, sloping from north-west to south-east. Its chief rivers are the Gumti, the Ghagra (Ghogra), and the Rapti, which swarm with alligators. The northern part, on the edge of the Himalaya, is not very well known. It forms a portion of the Terai, a vast unhealthy tract stretching along the borders of Nepal, and covered with impassable forests. The climate of O. is cool and pleasant from November to March; during the next four months it is hot and sultry, after which follows the long rainy season, but in general it is considered the healthiest along the whole valley of the Ganges. The soil is light, and except small nodules of chalk and oolite called *kankars*, there is hardly a loose stone to be seen. O. was formerly more copiously watered than it is now, the clearing of the jungles having greatly decreased the moisture of the land. The chief crops are wheat, barley, gram, masure, mustard, rice (of the finest quality), millet, maize, joar, bajra, various kinds of pulse and oil-seeds, sugar-cane, tobacco, indigo, hemp, and cotton. The manufacturing industry of O. is not important; soda, saltpetre, and salt are the only articles of which more is produced than is requisite for home-consumption. Gunpowder, and all kinds of military weapons, guns, swords, spears, shields, and bows of bamboo, or Lucknow steel, are, however, also made, besides some woollen goods,

paper, &c. Bridges are few, if any, and the roads in general bad. The principal is the famous military road from Cawnpore to Lucknow, which runs in a north-easterly direction.

The people are of a decidedly warlike disposition. The bulk of the inhabitants are Hindus, though the dominant race for centuries has been Mohammedan. The Brahmans are the most numerous class, but there are 29 different Rajput tribes. It is these two classes that mainly supplied the famous (or infamous) sepoys of the Bengal army. The language spoken is Hindustani.

The most characteristic feature in the social economy of O. is its *village-system*, for a description of which see INDIA. The *ryots*, or cultivators of the soil, cling to the land which their fathers have tilled for ages, with extraordinary affection, and thoroughly believe that they have a right of property in it; and, in general, we believe they are *actually* the owners of their farms, but in many cases they have been dispossessed by a class of tax-gatherers (resembling the Roman *publicani*) called *talukdars*, who farmed from the Mogul, and afterwards from the king of O., the revenues of a collection of villages called a *talukah*, and by their extortions so impoverished the *ryots*, or peasant-proprietors, that the latter were often forced to execute deeds transferring their property to the *talukdars*. Many of the more spirited would not submit to become *tenants*, and taking to the jungles, waged war on the new occupants of their ancestral lands, until gradually they sank into *dacoits*, or professional robbers. The extortions of the *talukdars* continued till the annexation of the country in 1856, and the country suffered severely from the retaliatory raids of the dispossessed *ryots*. The East India Company reinstated the *ryots* in their property, where the *talukdars* could not shew undisputed possession for 12 years—a proceeding which gave great offence to the latter, who, in consequence, assumed a coldly hostile attitude to the British during the great mutiny of the following year.

The principal towns are Lucknow (q. v.), Fyzabad, Oude, or Ayodhya, Roy Bareilly, and Shahabad.

O. is believed, by Sanscrit scholars, to be the ancient *Kosala*, the oldest seat of civilisation in India. The country was conquered by a Mohammedan army in 1195, and made a province of the Mogul empire. In 1753, the vizier of O., Saifdar Jung, rebelled against his imperial master, Ahmed Shah, and forced the latter to make the governorship hereditary in his family. His son, Sujah-ud-Dowlah, became entirely independent, and founded a dynasty which ruled the country, generally in a most deplorable manner, until, in the interests of the wretched inhabitants, the East India Company was forced to adopt the extreme measure of annexation, February 7, 1856. The necessity for this high-handed but most beneficent act will be better understood if we read the statistics of crime in O. during the last years of its independence: one item will suffice—from 1848 to 1854, there were, on an average, no fewer than 78 villages burned and plundered every year, while murders, robberies, abductions, and extortions were everyday occurrences. A feeble king, a blackguard soldiery, and a lawless peasantry had brought about a most helpless and ruinous anarchy. When the mutiny of 1857 broke out, O. became one of the great centres of rebellion. Upon this, the confiscation of all the estates of the *talukdars* was proclaimed by Lord Canning; but when the country was subdued by force of British arms, the estates of all such as laid down their arms and swore fealty to the British government were restored. The forts of the petty chiefs, however, were dismantled, and the inhabitants

disarmed. The province is now administered by a chief commissioner. The chief feature of the present condition of affairs in O. is the preservation in their integrity of the estates of the *talukdars*. The amount of government revenue paid by the *talukdars* is about £1,000,000.

OUDE, or AWADH, one of the principal towns of the province Oude (q. v.), stands amid ruins on a hilly site on the right bank of the Sarayū or Goggra River, 80 miles east of Lucknow. It is also called *Hanumangā'dhi*, on account of a temple erected there in honour of Hanumat (q. v.), the fabled monkey-ally of Rāma, an incarnation of the god Vish'nu. The name O. is a corruption of the Sanskrit *Ayodhyā* (from *a*, not, and *yodhya*, conquerable, hence 'the invincible' city); but the ancient city of that name was situated opposite the modern O., where its ruins may still be seen. Ayodhyā was one of the oldest seats of civilisation in India; it was the residence of the solar dynasty, or one of the two oldest dynasties of India, deriving its descent from the sun, but it obtained special renown through Rāma, the son of Das'aratha, a king of that dynasty. Its great beauty and immense size are dwelt upon in several of the Purānas and modern poems, but more especially in the *Rāmāyan'a* (q. v.), the first and last books of which contain a description of it. According to some Purānas (q. v.), Ayodhyā was one of the seven sacred cities, the living at which was supposed to free a man from all sin, and the dying at which, to secure eternal bliss. It was also called Saketa, Kos'alā, and Uttara-kos'alā. See Goldstücker's *Sanskrit Dictionary*, under AYODHYA.

UDENARDE, a town in the province of East Flanders, Belgium, is situated chiefly on the east bank of the Scheldt, 16 miles south-by-east from Ghent. It has a population of 8000, and possesses a fine Gothic council-house, important manufactures of linen and cotton fabrics, and many extensive tanneries. The town was taken by the French, aided by an English force, in 1653; it was again besieged in 1674, by the stadtholder, William (III. of England) of Orange; and in 1706, it was taken by Marlborough. An attempt made by the French to retake it, brought on the famous battle of Oudenarde, one of Marlborough's most celebrated victories, which was gained, on the 11th July 1708, with the aid of Prince Eugene, over a French army under the Duke of Burgundy and Marshal Villars. After this battle, the French king made offers of peace, which were not accepted.

UDINOT, CHARLES NICOLAS, Duke of Reggio, and Marshal of France, was born at Bar-le-Duc, in the department of Meuse, France, 25th April 1767. At the age of 17, he entered the army, but returned home after three years' service. Having distinguished himself in 1790 by suppressing a popular insurrection in his native district, he was, after some volunteer service, November 1793, raised to the rank of chief of brigade, in the fourth regiment of the line, and distinguished himself in various actions with the Prussians and Austrians. He was wounded and taken prisoner before Mannheim, by the Austrians, but was soon exchanged, and served in the armies of the Rhine under Moreau, and in that of Switzerland under Massena. He was promoted to be general of division (12th April 1799), and for a daring capture of a battery at Pozzola, was presented by the First Consul with a sabre of honour and the cannon which he had taken. In 1805, he received the Grand Cross of the Legion of Honour, and about the same time received the command of ten battalions of the reserve, afterwards known as the 'grenadiers Uudinot.' At the head of this corps, he did good service in the Austrian campaign. He was present

at Austerlitz and Jena, and gained the battle of Ostrolinka (16th February 1807), for which he was rewarded with the title of Count, and a large sum of money. He greatly contributed to the success of the French at Friedland, and was presented by Napoleon to the Czar Alexander as the 'Bayard of the French army, the knight *sans peur et sans reproche*.' He sustained his now brilliant reputation in the second Austrian campaign of 1809, and on the 12th of July was created Marshal of France, and on 15th of August, Duke of Reggio. In 1810, he was charged with the occupation of Holland, and by his unswerving probity and attractive personal qualities, drew the esteem of all classes. He was engaged in the disastrous Russian campaign, and subsequently took part in the various battles of 1813 between the French and the Russians and Austrians. He was one of the last to abandon Napoleon, but he did so for ever, and spent the period known as the 'Hundred Days' on his own estates. At the second restoration he became a minister of state, commander-in-chief of the royal guard and of the national guard, and was created a peer of France, Grand Cross of St Louis, &c. In 1823, he commanded the first division of the army of Spain, and was for some time governor of Madrid. After the revolution of July 1830, O. retired to his estates, and only at rare intervals presented himself in the Chamber of Peers. He became Grand Chancellor of the Legion of Honour in May 1839, succeeded Marshal Moncey as governor of the Invalides in October 1842, and died at Paris 13th September 1847. A statue was erected in his honour at Bar, 29th September 1850.—His son, CHARLES NICOLAS-VICTOR OUDINOT, Duke of Reggio (born 3d November 1791), was a general in the French army. He first distinguished himself in Algeria, and in the Revolution of 1848—having previously distinguished himself as a deputy (1842—1846) by his admirable talent for dealing with questions affecting the comfort and discipline of the soldiery—he was chosen commander-in-chief of the army of the Alps. In April 1849, he was appointed general of the French expedition against Rome, and forced the city to surrender unconditionally on the 1st of July, in spite of the heroic resistance of the republican triumvirs—Garibaldi, Mazzini, and Saffi. He was, however, not a Napoleonist, and at the *coup d'état*, 2d December 1851, shared the fate of every eminent general who would not violate his oath to obey the constitution—i.e., he was arrested and imprisoned. He was soon set at liberty, and lived in retirement until his death in 1863. O. wrote several books of military matters.

OUISTITI. See **MARMOSSET**.

OUNCE. The Latin *uncia* (derived by Varro from *unus*) was the name of the twelfth part of the *as* or *libra* (pound), and also was applied to the twelfth part of any magnitude, whether of length, surface, or capacity. Hence *inch*, the twelfth part of a foot. The modern ounce is a division of the pound-weight. See **POUND**.

OUNCE (*Felis Uncia*, or *Leopardus Uncia*), a large feline animal, nearly resembling the leopard, but having much rougher and longer hair, a longer and much more bushy tail; the general colour is also paler, the rosette-like spots are less sharply defined, and there is a black spot behind the ears. Little is known of the O.; it is described by Buffon, but naturalists were for some time generally inclined to regard it as identical with the leopard, and its name has been transferred in South America to the Jaguar. It is a native of Asia, and probably of mountainous districts.

OU'RARI. See **CURARI**.

OU'RO PRETO (black gold), a city of Brazil,
152

capital of the province of Minas Geraes, stands among barren mountains, 4000 feet above sea-level, and 200 miles north-north-west of Rio Janeiro. It contains the governor's residence and a college, and consists mainly of narrow and irregular streets. Although the neighbouring mountains are very auriferous, and although the mines were once the richest in the kingdom, the mining is now reduced to comparatively unprofitable washings. A good trade in coffee, &c., is carried on with Rio Janeiro, but is retarded by the want of good roads. The journey from O. P. to the capital of the empire is performed by horses and mules only, and ordinarily requires 15 days. Pop. about 4000.

OUSE, called also, for the sake of distinction, the **NORTHERN or YORKSHIRE OUSE**, a river of England, is formed by the union of the Swale and the Ure in the immediate vicinity of the village of Boroughbridge, and flows south-east past York, Selby, and Goole. About eight miles below the last town, it joins the Trent, and forms the estuary of the Humber. The length of its course from Boroughbridge is 60 miles, for the last 45 of which (from the city of York) it is navigable for large vessels. Its principal affluents are the Wharfe and the Aire from the west, and the Derwent from the north-east. The basin of the O., or the Vale of York, commences from the northern boundary of the county near the river Tees, from whose basin it is separated by a low ridge of hills, and extends southward, including almost the whole of the county. See **YORKSHIRE**.

OUSE, GREAT, a river of England, rises close to the town of Brackley, in the south of Northamptonshire, and flows north-east through the counties of Buckingham, Bedford, Huntingdon, Cambridge, and Norfolk, and falls into the Wash 2½ miles below King's Lynn. It is 160 miles in entire length, and is navigable for about 50 miles. It receives from the east and south the Ivel, Cam, Lark, and Little Ouse.

OUTCROP, a term applied in Geology to the edge of an inclined bed at the place where it rises to the surface. The line of the outcrop is called the strike, which is always at right angles to the dip.

OUTER HOUSE. See **COURT OF SESSION**.

OUTFIT ALLOWANCE, in the British Army, is a sum of £150 for the cavalry, and £100 for the infantry, granted to non-commissioned officers promoted to commissions, to enable them to meet the heavy charges for uniform and equipments. The larger sum is given in the cavalry, because the newly-commissioned officer has to purchase his charger.

OUTLAWRY, in English Law, means putting one out of the protection of the law, for contempt in wilfully avoiding execution of legal process. Formerly, in the common law courts, if the defender would not enter an appearance, certain proceedings were taken to outlaw him, so as to allow the action to go on without his appearance. These proceedings, however, are now abolished, and, in the majority of cases, it is immaterial as regards the action whether the defendant appear or not, provided he was properly served with the original writ of summons. After judgment, he may still be outlawed, as a preliminary to seizing and selling his property. In criminal proceedings, outlawry still exists as part of the ordinary practice to compel a person against whom a bill of indictment for felony or misdemeanour has been found, but who will not come forward to take his trial, and who has not been arrested. In such a case, process of outlawry against him is

awarded, which is a kind of temporary judgment; and while this process exists, he is out of the protection of the law, and forfeits all his property. The courts will not listen to any complaint or attend to his suit till he reverse the outlawry, which is generally done as a matter of course.—In Scotland, outlawry or fugitation is a similar process, and the defender must first be reponed against the sentence of outlawry before his trial can take place.

OUTPOSTS are bodies, commonly small, of troops stationed at a greater or less distance beyond the limits of a camp or main army, for the purpose of preventing an enemy approaching without notice, and also to offer opposition to his progress, while the main force prepares for resistance. Outguards march off to their position silently, and pay no compliments of any kind to officers or others. As soon as the officer commanding an outpost arrives on his ground, he proceeds to carefully examine the environs, noting all heights within rifle-range, roads and paths by which an enemy may approach, &c. He also takes such impromptu means of strengthening his position as occur to him—felling a tree here, cutting brushwood there, blocking a path in another place, and resorting to any expedient which may serve to delay the foe at point-blank range—an object of importance, as a stoppage at such a point is known to act as a great discouragement to advancing troops.

OUTRAM, SIR JAMES, LIEUTENANT-GENERAL, G.C.B., Indian soldier and statesman, was born, 1803, at Butterley Hall, Derbyshire, the residence of his father, Mr Benjamin Outram, a civil-engineer of note. His mother, the daughter of James Anderson of Mounie, Aberdeenshire, was descended from Sir W. Seton, Lord Pitmedden. O. was educated at Udn, Aberdeenshire, under the Rev. Dr Bisset, and afterwards went to Marischal College, Aberdeen. He was sent to India as a cadet in 1819, and was made lieutenant and adjutant of the 23d Bombay Native Infantry. He then took command of and disciplined the wild Bheels of Candeish, and successfully led them against the Daung tribes. From 1835 to 1838, he was engaged in re-establishing order in the Mahi Kânta. He went with the invading army under Lord Keane into Afghanistan as aide-de-camp; and his ride from Kheilat, through the dangers of the Bolan Pass, will long be famous in Indian annals. He became political agent at Guzerat, and commissioner in Sind, where he made a bold and earnest defence of the Ameers against the aggressive policy of General Sir Charles James Napier. He was afterwards resident at Sattara and Baroda, and upon the annexation of Oude, was made resident and commissioner by Lord Dalhousie. His health failing, he returned to England in 1856; but when the war with Persia broke out, and it became necessary to send an expedition to the Persian Gulf, O. accompanied the forces, with diplomatic powers as commissioner. He conducted several brilliant and successful operations; the campaign was short and decisive; and the objects of the expedition having been triumphantly attained, he returned to India. Landing at Bombay in July 1857, he went to Calcutta to receive Lord Canning's instructions, and was commissioned to take charge of the forces advancing to the relief of Lucknow. He chivalrously waived the command in favour of his old lieutenant, Havelock (q. v.), who had fought eight victorious battles with the rebels, and, taking up only his civil appointment, as chief-commissioner of Oude, tendered his military services to Havelock as a volunteer. Lucknow was relieved, and O. took the command, but only to be in turn besieged.

He held the Alumbagh against almost overwhelming forces, until Lord Clyde advanced to his relief. He then made a skilful movement up the left bank of the Gumti, which led to a final and complete victory over the insurgents. He was made chief-commissioner of Oude; and though he had strongly opposed its annexation, he was the man who did most to restore British rule, and attach the people to it. For his eminent services, he was promoted to the rank of lieutenant-general in 1858, and received the thanks of parliament in 1860. He took his seat as a member of the Supreme Council of India, in Calcutta, but sank under the climate, and returned to England in 1860, already stricken by the hand of death. The communities of India voted him a statue at Calcutta, founded an institution to his honour, and presented him with commemorative gifts. A banquet was given to him and his chief and companion-in-arms, Lord Clyde, by the city of London. His English admirers determined to erect a statue to his honour in London, and gave him a valuable desert-service in silver. He spent the winter of 1861—1862 in Egypt; and after a short residence in the south of France, expired at Paris, March 11, 1863. O. was styled by Sir Charles Napier the 'Bayard of India.' Than his, there is no more gallant name in the whole list of distinguished Indian soldiers. His services in the East as a soldier and a diplomatist extended over the period of forty years. He was ever the generous protector of the dark-skinned races among whom his lot was thrown, and set a bright example to all future administrators of moderation, conciliation, humanity, and practical Christianity. See the *Biography* by Sir F. Goldsmid (1880).

OUTRIGGER, in its proper sense, is a beam or spar fastened horizontally to the cross-trees or

Fig. 1.

otherwise, for the purpose of extending further from the mast or topmast the backstay or other rope by which that mast or topmast is supported. The power of the stay is thus increased. The term is also used improperly—because no 'rigging' is in question—to denote the apparatus for increasing the leverage of an oar, by removing the resistance, as represented by the side of the boat (see OAR), further from the power represented by the rower's hand. This is effected by fixing an iron bracket to the boat's side, the row-lock being at the bracket's extremity. The necessary leverage is thus obtained without adding to the width of the boat itself.

Fig. 2.

a, outrigger; b, side of boat.

OUTWORKS, in Fortification, are minor defences constructed beyond the main body of a work, for the purpose of keeping the enemy at a distance, or commanding certain salient points which it is undesirable that he should occupy. Such works are ravelins, lunettes, hornworks, crown-works, demi-lunes, tenailles, &c. They occur in certain necessary order, as a ravelin before the curtain and tenaille, a hornwork before a ravelin, and so on.

OUZEL, or OUSEL (Old Fr. *oise*, bird), an old name of the black-bird, as is evident from the descriptive lines of Bottom's song in *Midsummer Night's Dream*:

'The ouzel cock, so black of hue,
With orange tawny bill.'

It is also applied to other birds, chiefly of the thrush family. Thus, one British thrush is called the Ring Ouzel. The Dipper (q. v.) is very generally known as the Water Ouzel; and the Rose-coloured Pastor is also called the Rose-coloured Ouzel.

OVAL, the name given to the figure presented by a longitudinal section of an egg through its centre. The oval has a general resemblance to the ellipse; unlike the latter, however, it is not symmetrical, but is thicker at one end than the other, and at the thin end, narrows almost to a point. The term 'oval' is also used indiscriminately with 'nodus,' 'loop,' to denote the figure formed by a curve which either returns upon itself, as the lemniscata, &c., or the loops of the cubical and semi-cubical parabolas and other curves. In scientific language, it is specially distinguished from the term 'elliptical,' with which, in common parlance, it is usually confounded.

OVAMPOS AND OVAMPOLAND. The Ovampo or Otjiherero are a tribe, seemingly a connecting link between the Kaffir and Negro races, who inhabit the region north of Great Namaqualand, in South Africa, extending north to the Cuanene River, and south to the parallel of 23° S. lat. The Ovampo tribes are described by Anderson as of a very dark complexion, tall and robust, but remarkably ugly. He found them, however, honest, industrious, and hospitable. They are not entirely pastoral, but cultivate much corn. Living in the same country are the Cattle Damarae, with still more of the Negro type, a stout, athletic people, very dirty in their habits, and generally armed with the bow and arrow. They live in a state of constant warfare with the Ghondannup, or Hill Damarae, a nearly pure Negro race, on the one hand, and the Namaqua Hottentots, who live south of them, on the other.

Ovampoland is a more fertile region than Namaqualand, from which it is separated by a wide belt of densely-bushed country. It has but few rivers, and these not of a perennial nature. About 50 miles from the coast, the country rises to a tableland about 6000 feet above the sea-level, and then declines to the south and east into the deserts of the Kalihari, and the region of Lake Ngami. Many strong indications of copper-ore are found in various places. The principal rivers, or rather water-courses, are the Swakop, Kuisip, and their branches, which enter the Atlantic a few miles north of Walvis Bay. The other rivers in the interior seem to lose themselves in the sands. The climate is healthy, except near the coast, where fever in some seasons prevails. It seldom rains in the coast region, which is a very desolate one, and almost devoid of water. Thunder-storms are very violent in the summer season. All the large mammalia are found, more or less plentiful, according as water may be found at the different drinking-places. Elephants, rhinoceroses, elands, and other large animals driven from the south by the march of civilisation, take refuge in the desert region lying east of Ovampoland, where sportsmen like Green and Anderson have been known to kill as many as twelve elephants in a day. The country was first described by Sir J. Alexander, who visited its south border. Mr Galton afterwards penetrated much further north; and Mr C. J. Anderson has since fully explored it nearly as far

north as the Cuanene. Large numbers of horned cattle are annually collected by traders from the Cape in these regions, and whales abound on the coast. The trade in ostrich-feathers and ivory is of increasing importance, and several trading-stations are established for the collection of native products. Some elementary works have been printed in the Otjiherero dialect.

OVARIES are organs peculiar to the female, and are analogous to the testes in the male. They are two oblong flattened bodies (about an inch and a half in length, three-quarters of an inch in width, and nearly half an inch thick in the human subject), situated on either side of the uterus, to which they are connected by ligaments and by the Fallopian tube.

The ovary is composed of two well-defined portions, a superficial or 'cortical' portion, and a deep or 'medullary' portion. The whole is inclosed in a tough fibrous coating, which is, however, closely blended with the cortical portion, and cannot be stripped off. It is termed the *tunica albuginea*. The medullary portion is highly vascular, and of a reddish colour. The cortical portion in the adult ovary contains an enormous number of vesicles, varying greatly in size. These are the *Graafian follicles*, and contain the ova or germs—the female element of reproduction. Their number is estimated at 30,000. From ten to twenty large and more or less mature vesicles are found near the surface, to which they gradually approach as they become developed. The structure of these ovisacs and their contained ova is somewhat complex, and cannot be described here. More or less coincident with menstruation is the process of *ovulation*, by which is meant the rupture of the wall of Graafian follicle, and the escape of the contained ovum. On its escape from the ovary, the ovum enters the end of the Fallopian tube, by which it is conveyed into the uterus.

Immediately after the escape of the ovum, the empty follicle becomes filled with blood. The wall of the follicle increases in thickness owing to the multiplication of its component cell elements. The pigment of the blood undergoes a change, and becomes bright yellow in colour. This body is termed the *corpus luteum*. Should the discharged ovum escape from the uterus without becoming impregnated, the corpus luteum reaches its full size in three weeks, and gradually becomes absorbed, and at the end of nine weeks is represented by merely a minute pucker. Should pregnancy occur, the corpus luteum increases in size for two months, remains stationary for four months, then decreases in size during the remainder of pregnancy, but is permanently represented by a well-marked cicatrix. This latter is termed the *true corpus luteum*, to distinguish it from that of menstruation.

The ovary is the subject of several diseased conditions. (1) It is the seat of acute and chronic inflammation. This may arise from injuries during labour, operations in the pelvis, but very frequently is the result of gonorrhoeal infection, spreading from the vagina. Such inflammations cause great organic changes in the structure, often leading to sterility, and they are usually associated with severe pain, frequently so intense as to unfit the subject for all active duty. (2) The ovary is the seat of new growths, which may be of several varieties. Some represent enlargements of one or more Graafian follicles, and attain an enormous size, sometimes weighing 100 pounds or more. They contain fluid which is usually of a viscid, ropy nature, and brownish colour; but sometimes presents other characters. These are known as *ovarian cysts*. Other tumours are of a more or less solid nature,

and contain portions of hair, teeth, bone, &c., and are known as *dermoid tumours*. Moreover, either tumour may become the seat of cancerous disease.

The treatment of ovarian disease by the removal of the offending organ, is one of the triumphs of modern surgery. Formerly, relief in cystomata was only obtained temporarily by tapping, that is, withdrawing some of the fluid by means of a trocar and canula. But the tumour almost always filled again, and though tapping might be repeated time after time, the patient ultimately succumbed. Now the abdominal wall is laid open, the tumour emptied as much as possible of its contents, the collapsed sac drawn through the incision, its neck secured by ligature or otherwise, the mass cut away, the stump returned to the abdomen, and the wound carefully closed by stitches.

Fifty years ago the operation was performed by a few surgeons, under the protest of the great majority of the medical profession; now it takes its place as a routine operation, demanded in any suitable case, and performed with results as regards the saving of life and restoration to health, together with an immunity from risk, which can be claimed by no other major operation. The operation for extirpation of ovarian cystoma was first performed by Ephraim McDowell of Kentucky, in 1809, but was established in England as a regular operation by Charles Clay, of Manchester, who operated on his first case in 1842. Clay operated on nearly 400 cases with 69 per cent. of recoveries. Since then the operation has been performed many thousands of times, and the mortality has been reduced to a figure which renders the operation, while always one of the gravest, yet, in competent hands, one of the safest in surgery. To this result the labours in this country of Spencer Wells, Thomas Keith, and Lawson Tait have mainly contributed. With the best operators, the mortality at this moment is probably not more than 6 per cent. This result has been ascribed to various causes, such as the mode of treating the pedicle, or stump, the use of antiseptics, &c.; but is probably most due to the experience acquired in dealing with the various complications and difficulties arising in the operation.

Within the last few years the removal of the ovaries and Fallopian tubes for other than cystic disease, has come to be recognised as a regular operation, and is now frequently performed. The conditions which are considered as demanding this are: (1) Chronic inflammation in the ovaries or tubes, resulting in the formation of pus, &c. in the latter, or which gives rise to intolerable pain and discomfort, rendering life utterly miserable. (2) Cases of fibroid tumour of the uterus, in which life is threatened by the great loss of blood which these tumours often cause. Removal of the ovaries in these cases is usually followed by cessation of growth and shrinking of the tumour, and entire stoppage of serious hemorrhage. The question as to the beneficial effects of the interference in all cases falling under the former class is still *sub judice*, but the advantage of the procedure in the second group of cases is almost universally admitted. The name of Lawson Tait is specially associated with this operation.—Consult *Diagnosis and Treatment of Abdominal Tumours*, by Sir Spencer Wells (1885); *Diseases of Women*, by Lawson Tait (1885).

OVEN. The usual time-honoured bakers' oven is a low vaulted chamber of stone or brick. The furnace is near the small door at one end, the flue for the exit of the smoke at the other end. The oven is fired with wood fuel, and when it is sufficiently heated, the fire is withdrawn, and the dough

quickly put in on long wooden shovels. Of late, numerous plans have been devised which heat the oven by a fire outside the baking area, flues of various arrangement carrying the heated gases of combustion below and around the place where the dough is being baked. This has the advantage of allowing baking to go on continuously (whereas in the old oven heating and baking take place only alternately), of permitting the use of coals, less costly than wood, and of avoiding the dirtying of the bread. In some ovens, the sole is capable of rotating, and of being so raised and lowered as to bring first one side, then the other, nearest the heat. In some, used especially for baking biscuits, the dough is laid on metal or stoneware plates fixed on an endless chain, and kept moving. Perkins's oven is heated by means of numerous pipes through which a current of super-heated water and steam circulates. Perkins's and the Bailey-Baker patent received gold medals at the Health Exhibition of 1885. In Thomson's gas oven, and the Yorkshireman, gas burners supply the heat. A disadvantage in most of the ingenious new types of oven is their costliness; and in several of them the interior of the oven is kept too dry, and so hurts the flavour of the bread. See BREAD, UNFERMENTED BREAD. Kitchen-ranges and cooking ovens are often well fitted for baking bread and pastry for domestic use. Ovens for army use in barracks or the field are generally arranged so as to be serviceable for cooking meat, roasting potatoes, coffee, &c., as well as baking bread; in those for the field, portability is a main essential. See BREAD (ARMY); BAKERIES (ARMY); COOKERY (ARMY). The name oven is also used of coke ovens. These will be found described at COKE. See also STOVE.

OVEN BIRD. See SUPP., Vol. X.

O'VER DA'RWEN, a very flourishing municipal borough and township of Lancashire, situated amid moorland hills, $3\frac{1}{4}$ miles south of Blackburn, and $19\frac{1}{4}$ miles north-west of Manchester. In less than twenty years it rose from a small hamlet to a populous town. The main cause of the prosperity of the town has been chiefly owing to the abundance of coal, stone, and water which exist in the locality. The cotton trade is the staple manufacture of the town. The 'India Mill,' erected to contain 100,000 spindles, is a stone building in the Italian style, with engine-house, chimney, &c. highly ornamented. The town also contains the most extensive paper-staining works in England, several paper manufactories, a calico-printing establishment, as well as works for the manufacture of fire-bricks, tiles, and sanitary tubes, iron and brass founding, bleaching, machine and reed making. Coal-mines and stone quarries also find employment for a considerable number of the inhabitants. The town possesses several club-houses, a covered market, public baths, and a valuable free library. The central stores of the Industrial Co-operative Society, erected in 1887, at a cost of £10,000, contain a large public hall; and the society maintains science classes, an extensive library, and well-supplied news-rooms. Pop. (1851) 11,702; (1861) 16,492; (1871) 21,278; (1881) 29,747.

OVERBECK, FRIEDRICH, born at Lübeck, July 3, 1789, was a very distinguished painter, to whom belongs a large share in the movement from which arose the modern German school of art, and the Christian art of the 19th c. He commenced his studies as an artist at Vienna in 1806 as a pupil of the pseudo-classical school of David; but having adopted notions on art essentially different from those inculcated in the academy, he was expelled along with some like-minded friends, and in 1809

set out for Rome. His principle, now and always, was to abjure the classical Renaissance and its sensuousness, and to 'abide by the Bible.' In Rome he was soon afterwards joined by Cornelius, Schadow, and Veit; and it was these four who laid the foundation of a school that in no small degree influenced the taste for art in Europe, though they were scoffed at as 'Pre-Raphaelites,' 'Nazaries,' 'Church-Romantic painters,' and had long to struggle with poverty. A picture of the Madonna, which O. painted at Rome in 1811, brought him into marked notice. He was next employed, along with Cornelius and his other friends, by the Prussian consul, Bartholdi, to execute for his house at Rome frescoes illustrating the history of Joseph, the 'Selling of Joseph' and the 'Seven lean Years' being the subjects assigned to him. After completing these, he painted in fresco, in the villa of the Marchese Massimi, five large compositions from Tasso's *Jerusalem Delivered*. In 1813, along with some of his artistic brethren, he abjured Lutheranism, and embraced the Roman Catholic religion. O.'s chief work is a fresco at Assisi, 'The Vision of St Francis.' His oil pictures are inferior to his frescoes, being dry and weak in colour. Among his famous pictures are Christ's Entry into Jerusalem, at Lübeck; Christ's Agony in the Garden, at Hamburg; *Lo Spasalizio*, at Berlin; *The Triumph of Religion in the Arts*, at Frankfurt; the *Incredulity of St Thomas*, in a private house in London. He executed a great many drawings and cartoons remarkable for noble feeling, most of which, like his frescoes and paintings, have been engraved. One of his last undertakings, a series of designs from the Evangelists, delicately engraved in the line manner, is a work of high excellence. O. adhered closely to those ideas of art with which he started—namely, entire devotion to the style of the Italian artists prior to the period of the Renaissance—Fra Angelico, Pinturicchio, Perugino, and Raphael in his early period—and a strong conviction that form or drawing in the classic style is inadmissible in works embodying religious subjects. Many of his compatriots—Cornelius, for instance—modified and enlarged these ideas, and studied the works of Michael Angelo and those of Raphael's later style, executed under the influence of classic art. Amongst the characteristics of the art of the school are devout feeling, hardness of outline, scholastic composition, and the avoidance of merely sensuous beauty both in colour and form. The success of the school in fresco led to a notable revival of the long-neglected art. O. resided in Rome from the time he went there as a student, and was a devout and saintly man. He wrote poems, essays, and a mass of letters on congenial topics. He died November 1869.

OVERBURY, SIR THOMAS, an English author and courtier, whose mysterious death has given a peculiar interest to his history, was the son of Nicholas Overbury, a Gloucestershire squire, and was born at Compton Scorden, Warwickshire, the residence of his maternal grandfather, in 1581. He studied at Oxford, where he graduated in 1598. He then joined the Middle Temple, but soon after set out for the Continent, from which he returned with the reputation of being a finished gentleman. While on a visit to Scotland in 1601, he met for the first time with his future enemy, Robert Carr (properly Ker), then a page in the service of the Earl of Dunbar. An intimacy unfortunately sprang up between the two, and Carr—a handsome ignoramus, sensual and unprincipled—followed his scholarly friend to London. On the accession of James to the English throne (1603), Carr rose rapidly into royal favour, and was created

Viscount Rochester. Through his influence, O. was knighted in 1608. In return, O. gave his patron the benefit of his wit and judgment.

At the age of thirteen, Frances Howard, daughter of the Earl of Suffolk, was married (1606) to the Earl of Essex, himself only a year older. On account of their youth, it was reckoned advisable by their friends that they should not live together for some time. The boy-husband went away on his travels, and the wedded girl to her mother. After the lapse of nearly five years, Essex came home, and found his wife, now a splendid beauty of eighteen, the idol of all the court gallants. But there was not a touch of virtue or goodness in her whole soul. For her husband she shewed the greatest aversion, and only consented to live in his house at the command of the king. It was well known that she had had intrigues with more than one lover, but in particular with Rochester, for whom she now cherished a fierce passion. O. had been instrumental in bringing about their guilty intercourse, and was now to reap the reward due to a pander. Rochester having told him that he purposed to get Lady Essex divorced from her husband, and then to marry her, O. strongly deprecated the idea, and declared that it would be disgraceful to form a union with so depraved a creature—she might do for a mistress, but not for a wife! The earl told Lady Essex what O. had said of her; she became furious for revenge, and offered Sir David Wood (between whom and O. there was a standing quarrel) £1000 to assassinate him, which that canny Scot declined to do. Rochester, it has been held, himself was now persuaded by his mistress to join privately in a plot against O., who on a most trivial and illegal pretext was thrown into the Tower, April 21, 1613. When O. had assured himself of Rochester's treachery, he threatened to divulge certain secrets in his possession, whereupon it was determined that he should be poisoned. This, after several trials, was successfully accomplished, and O. expired on the 15th of September. Rochester (now created Earl of Somerset), and his paramour were married on the 26th of December with great pomp, and the whole affair was soon to appearance forgotten. But after George Villiers had supplanted the earl in the royal favour, an inquiry was instituted; four of those concerned in the plot were executed; Somerset and his wife were tried and found guilty of poisoning, but were, by an amazing stretch of the royal prerogative, pardoned. It has been assumed that the motive of James's clemency was to conceal secrets discreditable to himself, but it should be remembered that, though the countess was unquestionably guilty, the complicity of Somerset himself was never proved; and Mr Gardiner, in his *History of England*, affirms his belief that Somerset was not guilty.

O. wrote several works, all of which were posthumously published. The principal are, *The Wife* (1614), a didactic poem; *Characters* (1614), the wit, ingenuity, precision, and force of which have long been admitted; *Crumbs fallen from King James's Table* (1715). An edition of O.'s works, with *Life*, was published by E. F. Rimbault in 1856.

OVERLAND ROUTE to India is that from England across the Continent of Europe and the Isthmus of Suez; and is only about half as long as the voyage round by the Cape of Good Hope, a little over 6000 miles instead of more than 12,000. The saving in time is even more considerable. In the old days, a voyage to India and back was a matter of years; ultimately the single voyage by sailing vessel was accomplished on this route in about four months. By steamer, the roundabout

voyage takes three months. Now the most direct Overland Route is from London by Calais through the Mont Cenis or St Gothard Tunnel by rail to Brindisi, thence to Port Said by steamer, and so through the Suez Canal and Red Sea to Bombay; and this journey can now be made in 21 days. A somewhat longer route is across country to Mar-seilles, Trieste, or Naples, and thence to Alexandria or Port Said. The maintenance of this communication with our Indian Empire, China, and Japan, is mainly due to the Peninsular and Oriental Company, incorporated in 1840. Lieutenant Waghorn devoted great part of his life to showing how the voyage from India could be shortened, and in 1845 made a passage with the mails from Bombay, between the 1st October and the 31st of the same month, the shortest time in which the transit had ever been accomplished. The railway from Suez to Alexandria by Cairo was opened in 1858; but the great event in the rendering of the advantages of the Overland Route available for passengers generally, was the opening of the Suez Canal in 1869. Passengers who dislike the fatiguing railway journey to Brindisi, may embark at London and sail by Gibraltar and Malta, through the canal to Bombay; and so enjoy most of the advantages of the Overland Route without leaving the ship or going over land at all. This is now the usual route for merchandise also. From Bombay one can go by rail to Madras and Calcutta, or sail all the way by the Point de Galle. From Point de Galle other steamers run to Singapore, Shanghai, Yokohama, &c.; also to the Australian ports. Australians benefit by the Suez route as much as Anglo-Indians, and the Orient and other lines of steamers, with slightly varying routes, have rendered the voyage to Australia very short compared with what it used to be. Under the head of Overland Route would come the Euphrates Valley Railway, if ever such an alternative land route through Syria to India should be made practicable. Another scheme for simplifying the voyage to India is by connecting the Jordan Valley with the Mediterranean on the one hand, and the Gulf of Akaba, a branch of the Red Sea, on the other. The value of swift and direct communication with India is sufficiently obvious, even apart from its enormous importance in a military and imperial point of view. It is the existence of the Overland Route to India that has given Britain its peculiar interest in Egypt and Egyptian affairs.

O'VERSEERS are officers appointed annually in all the parishes in England and Wales, whose primary duty it is to rate the inhabitants to the poor-rate, collect the same, and apply it towards giving relief to the poor. These officers occupy an important position in all English parishes. They were first ordered to be appointed in each parish by the statute of 43 Eliz. c. 2, the leading Poor-law Act, which directed four, three, or two substantial householders in the parish to be nominated yearly, and a later statute fixed the time of nomination to be 25th March, or a fortnight thereafter. The courts have held that not more than four, nor less than two, can be appointed, the object being, probably, that so much responsibility should not be thrown on any one individual. Though it is usual for the vestry of the parish to nominate two persons to be overseers, still those who really appoint them are the justices of the peace, who are not bound to regard the wishes of the vestry in this respect. It is only householders in the parish who are qualified for the office, and though it is not necessary that they should actually reside in the parish, still they must occupy or rent a house there. Several classes

of persons are exempt from serving the office, such as peers, members of parliament, clergymen, dissenting ministers, barristers, attorneys, doctors, officers of the army and navy, &c. But all who are not specially exempted by some statute are liable to serve the office, and even women may be appointed, though they scarcely ever are so in practice. The office is compulsory, and entirely gratuitous; and so necessary is it that some one shall fill the office, that it is an indictable misdemeanour to refuse, without cause, to serve when duly appointed. Though overseers are the proper managers of the poor for each parish, yet some parishes, especially in large overgrown towns, have been regulated by local acts, and guardians of the poor provided; and other parishes are under what is called a select vestry. In such cases, the overseers, though still appointed, are only allowed to give relief to paupers in certain urgent and exceptional cases, the ordinary regulation of poor-law affairs being confined to the guardians or the select vestry. The primary duty of the overseers consists in making, collecting, and applying the poor-rate for the relief of the poor of the parish, but, as will be seen, advantage has been taken by the legislature of the existence of these officers always representing the parish, to throw upon them various miscellaneous duties which are not directly connected with poor-law affairs.

1. Of the duties connected with the management of the poor. The overseers along with the churchwardens are to make a rate once or twice a year; i.e., a list of all the occupiers of lands and houses in the parish, specifying their names and the property occupied by each, and the ratable value and amount due by each. The next thing to be done is to go before two justices of the peace, and get the rate allowed—i.e., signed by them—and then it is published on the church-door on the following Sunday. The overseers must collect the rate also; but in all large parishes there is a collector of poor-rates who is specially appointed and paid for the purpose of collecting it. If a party refuses to pay the rate, the overseers must take proceedings before justices to compel payment, which is done by distraining the goods of the party, or, if there are no sufficient goods, by getting a warrant to imprison him. The party may, however, appeal against the rate to the Court of Quarter Sessions. When the money is collected, the overseers have to apply it towards the relief of the poor, and many other purposes of a kindred nature. Relief must be given to all the poor in the parish who are in a destitute state; but it is the duty of the overseers, when the pauper has not a settlement in the parish, to obtain an order of removal, i.e., to get an order of justices, under which the pauper is taken by force, and sent to the parish where he has a settlement. See **REMOVAL OF THE POOR**. Relief is given, in general, only in the workhouse, and according to certain rules and conditions. Where the parish is included in a poor-law union, as is now generally the case, then the duty of overseers in giving relief is entirely confined to certain urgent cases; for the guardians of the union administer the ordinary business of the workhouse, and of relief generally. Another duty incident to overseers of a parish in a union is the duty of making out valuation lists—i.e., a new valuation of the property in the parish—which list is ordered by the guardians with a view to produce some uniformity in assessing the burdens on the various occupiers. Formerly, the mode of valuing property for the purposes of the poor-rate was not subject to any uniform rule, and in some parishes the valuers made a larger deduction from the actual value than in others; but in 1862, a statute passed, called the Union Assessment Act,

the object of which was to enable new valuations to be made on a uniform plan, till the occupiers in all the parishes are treated alike. At the end of the year of office, the accounts of the overseers of parishes in unions are audited by a poor-law auditor, who is a paid officer, and who examines the vouchers, and sees that no illegal payments have been made.

2. The miscellaneous duties now imposed by statute on overseers, over and above their original duty of relieving the poor, are numerous. The most prominent, perhaps, is that of making out the list of voters for members of parliament. This duty is done in obedience to certain precepts issued by the clerk of the peace each year, who gives the overseers full instructions how to make out the lists, and what claims and objections to receive, and how to deal with them. The overseers must also attend the court of the revising barrister, when he revises the lists, and disposes of legal objections. Another duty of the overseers is to make out the list of persons in the parish qualified to serve as jurors. So they must make out the burgess lists when the parish is situated within a borough. They must also make out the list of persons qualified to serve as parish constables. They are also bound to appoint persons to enforce the Vaccination Acts; they must give notice to justices of all lunatics within the parish, and pauper lunatics are removed to the county asylum. They must also collect and enforce payment of the rates levied to pay the expenses of school-boards. The overseers must also perform certain duties as to the election of guardians for the union. They must also bury the dead bodies of persons cast on shore, and of all paupers who die in the parish. They also are the proper parties to protect village greens from nuisances; and in general, where there is no local Board of Health, the overseers are the parties bound to act in carrying out the Nuisances Removal Acts (see *NUISANCE*) within the parish, which of itself is an onerous duty. In general, whenever overseers are bound to do miscellaneous duties of this kind, they are authorised to pay the necessary expenses and disbursements out of the poor-rate; but, as already stated, their services are gratuitous. The duties which in England are performed by overseers, devolve, in Scotland, upon the parochial board, the sheriff-clerk of the county, session-clerk, and others.

OVERSEER, ASSISTANT. An assistant overseer is a paid officer, whose services have generally been found necessary in the larger parishes, in order to relieve the annual overseers of their burdensome office to some extent. Accordingly, the ratepayers, in vestry assembled, appoint a person as assistant overseer with a salary, who performs most of the same duties as the overseers. In many cases, however, a collector of poor-rates has been appointed, who is also paid by salary, and in such a case he discharges like duties. Both the assistant overseer and the collector of poor-rates are bound to find security for the faithful discharge of their duties, and for duly accounting for moneys in their hands.

OVERSTONE, SAMUEL JONES LOYD, LORD, one of the most skilful political economists, and the ablest writer on banking and financial subjects that this country has produced. He was born in 1796, being the only son of Mr Lewis Loyd, descended from a respectable Welsh family, and a leading partner in the eminent banking house of Jones, Loyd, and Co. of London and Manchester. Having gone through a regular course of instruction at Eton, young Loyd was sent to Trinity College, Cambridge, where he had Dr Blomfield, late Bishop of London, for tutor, and where he acquired a very

extensive acquaintance with classical literature, and with the history and literature of his own country and of Europe generally. On leaving Cambridge, Loyd entered the banking-house as a partner along with his father, and on the retirement of the latter, he became its head. He distinguished himself highly in his capacity of banker. He had a profound knowledge of the principles of banking, and these he applied on all occasions in conducting the business in which he was engaged. Far-sighted and sagacious, he was seldom deceived by appearances or pretensions, however specious. Perhaps, if anything, he was too cautious; but he was neither timid nor irresolute. He was eminently successful in the employment of the very large deposits at his command, and while he eschewed hazardous transactions, he did not shrink from engaging in very extensive operations when he believed they could be undertaken with a due regard to that safety which should always be the first consideration in the estimation of a banker.

Loyd entered parliament in 1819 as member for Hythe, which he continued to represent till 1826. He made several good speeches in the House; and was one of a small minority that voted for the proposal to make bankers issuing notes give security for their payment. Though opposed to all changes of a dangerous or revolutionary character, Loyd was always a consistent Liberal. Having either withdrawn, or being on the eve of withdrawing from business, Loyd was raised to the peerage in 1850, by the title of Baron Overstone and Fotheringhay, county Northampton; and if great wealth, consummate intelligence in regard to matters of great public importance, and the highest degree of integrity and independence, be qualifications for a seat in the Lords, few peers had a better title to be enrolled in that august assembly.

The first of Lord O.'s famous tracts on the management of the Bank of England and the state of the currency was published in 1837, and was followed by others between that period and 1857. The proposal for making a complete separation between the banking and issue departments of the Bank of England, introduced by Sir Robert Peel into the act of 1844, was first brought forward in these tracts, and its adoption has been the greatest improvement hitherto effected in our banking system. Having been collected, these tracts were published in 1857, with extracts from evidence given by Lord O. before committees of the Lords and Commons. And it would not be easy to exaggerate the value of this volume. Lord O. also reprinted, at his own expense, four volumes of scarce and valuable tracts on metallic and paper money, commerce, the funding system, &c. The volume, which concerns itself with commerce, contains some of the productions of Sir Walter Raleigh, John Evelyn, and Daniel Defoe.

An inquiry took place before a committee of the House of Commons in 1857 into the practical working of the act of 1844, and Lord O. was the principal witness who came forward in defence of the act; but several leading members of the committee being hostile to it, exerted themselves to overthrow his lordship's theories and opinions; which gave Lord O. the opportunity of successfully vindicating the principles and practical working of the act. This evidence was published in 1857.

Lord O. was currently believed to have been worth £6,000,000 or £8,000,000, but after his death, 17th November 1883, his personal estate was sworn under £2,118,803. Lord O. was a zealous opponent of the principle of limited liability. He was a leading member of the commission appointed to inquire into the proposal for the introduction of

a decimal system of arithmetic, and powerfully advocated the opinion that it would be injurious rather than beneficial. Lord O. was chairman of the Irish Famine Committee in 1847; a promoter of the Great Exhibition of 1851; a trustee of the National Gallery in 1850, and one of the senators of the University of London. O. married a daughter of Mr Ichabod Wright of Mapperly Hall, Notts, in 1829.

OVERTON, a parliamentary borough and parish in Flintshire, North Wales, on the river Dee, 20 miles N.N.W. of Shrewsbury. It constitutes part of the Flintshire district of parliamentary boroughs, and O. is the polling place for the county.—O. is also the name of a village in Lanarkshire, Scotland; in Hants, Lancashire, and Wiltshire, and of a parish in Yorkshire.

OVERTURE (from Fr. *ouverture*, opening), a musical composition for a full instrumental band, introductory to an opera, oratorio, cantata, or ballet. It originated in France, and received its settled form at the hands of Lulli. Being of the nature of a prologue, it ought to be in keeping with the piece which it ushers in, so as to prepare the audience for the sort of emotions which the author wishes to excite. Such is to a great extent the character of the beautiful overtures by Mozart to *Zauberflöte* and *Don Giovanni*, by Weber to *Freischütz*, and by Mendelssohn to his *Midsummer Night's Dream*, which are enriched by snatches of the more prominent airs in these operas. In the end of last century, overtures were written by Haydn, Pleyel, and other composers, as independent pieces to be played in the concert room; this sort of overture being, in fact, the early form of what was afterwards developed into the SYMPHONY (q. v.). The overture, as well as the symphony, is designated by the name *sinfonia* in Italian.

OVERTURE, a technical term common in the procedure of the Scottish ecclesiastical courts, is used of a proposal, legislative or administrative, sent up by one of the inferior courts of the various Presbyterian churches to the supreme court of that church, to be there examined and, if approved, passed into an act. It is of course also derived from the French *ouverture*.

OVERWEG, ADOLF, a German traveller, born at Hamburg 24th July 1822. He studied natural science at Bonn and Berlin, and, in 1850, accompanied Barth and Richardson on their expedition to Central Africa. It was from his observations that our knowledge of the levels of the Sahara is chiefly derived. Alone he explored great part of Lake Tchad, and alone or with others examined various tributaries of that lake and the country watered by them. He died near the lake 27th September 1852.

OVERYSSEL, a province of the Netherlands, is bounded on the N. by Friesland and Drenthe; E. by Hanover and Westphalia; S. and S.W. by Gelderland; and W. by the Zuider Zee. It has an area of 1274 square miles; and (1880) a population of 276,246. The soil is sandy with clay lands by the Yssel, rich pastures along the Zuider Zee and rivers, tracts of peat-land in various parts, and extensive heaths which are gradually being brought into cultivation. From south to north the province is intersected by an unbroken chain of sand-hills. The chief cities are Zwolle, Deventer, and Kampen; important manufacturing towns of less note being Almelo, Avereest, Dalfsen, Haaksbergen, Hardenberg, Hellendorf, Lonneker, Losser, Raalte, Staphorst, Steenwykerswold, &c. The principal employments are—agriculture, manufactures of various kinds, fishing, making peat, shipping, and merchandise.

Carpets are manufactured at Deventer and Kampen, leather at Blokzyl, calicoes and other cotton fabrics at Kampen, Almelo, Dalfsen, Ommen, and many other towns. There are extensive brick-works at Ryssen, Zwollerkerpel, Markelo, and Diepenveen, producing a yearly aggregate of 43,760,000. Ship-building is carried on at Zwartsluis, Vollenhove, Steenwykerwold, and elsewhere.

The principal rivers are the Yssel, into which the Schipbeek runs, and the Overyssele Vecht, which falls into the Black Water. Other important water-ways are the Dedems-Vaart and the Willems-Vaart canals. There were, in 1873, 109 miles of railways in the province. The island of Schokland, in the Zuider Zee, belongs to Overyssele.

OVID (PUBLIUS OVIDIUS NASO), the descendant of an old equestrian family, was born on the 20th March 43 B.C., at Sulmo, in the country of the Peligni. He was educated for the bar, and under his masters, Arellius Fuscus and Porcius Latro, he became highly proficient in the art of declamation. His genius, however, was essentially that of the poet, and the writing of verses began to absorb the time that should have been spent in the study of jurisprudence. His father, having but a scanty patrimony to divide between two sons, discouraged this tendency in the younger, but in vain. By the death of his elder brother, O. inherited all his father's property, and went, for the completion of his education, to Athens, where he acquired a perfect mastery of the Greek language. He afterwards made a tour in Asia and Sicily along with the poet Macer. It is uncertain whether, on his return to Rome, he ever practised as advocate. Although by birth entitled to aspire to the dignity, he never entered the senate; his weakness of body and indolence of habit prevented him from ever rising higher than from the position of triumvir capitalis to that of a decemvir, who convened and presided over the court of the centumviri. While his public life was unimportant, his private was that of a gay and licentious man of letters. The restraint of the matrimonial tie was always distasteful to him; twice married in early life, he soon divorced each of his wives; while he carried on an intrigue with a lady whom he celebrated as Corinna, and who is believed to have been no other than Julia, the accomplished daughter of Augustus. Before his thirtieth year, he married a third time, and became the father of Perilla, of whom he was tenderly fond. Up till his fiftieth year, he resided chiefly at Rome, in a house near the Capitol, and occasionally visited his Pelignian estate. His society was much courted, and his large circle of distinguished friends included Augustus and the imperial family. By an edict of the emperor, however, he was, in 9 A.D., commanded to leave Rome for Tomi, a town near the delta of the Danube, and on the very limit of the empire. The sentence did not condemn him to an *exilium*, but to a *relegatio*—or in other words, he did not lose his citizenship, nor was he cut off from all hope of return. The cause of this sudden banishment has long divided the opinion of scholars, since the one mentioned in the edict—the publication of his *Ars Amatoria*—was a mere pretext, the poem having been in circulation for ten years before. His intrigue with Julia, or with Julia's daughter, and the consequent displeasure of Augustus or of Livia, have been adduced with various degrees of plausibility, as the cause of a sentence to which O. himself only mysteriously refers. The misery of his life on the inhospitable and barbarous shore of the Euxine is commemorated by the poems in the composition of which he found his solace. He became a favourite with the Tomits, whose language he learned, and before

whom he publicly recited some poems in honour of Augustus. But his devotion to the emperor, and the entreaties addressed to the imperial court by himself and his friends, failed to shorten the term, or to change the scene of his banishment; so he died, an honoured citizen of Tomi, 18 A.D., in his sixtieth year. His works which have come down to us, either in whole or in part, appeared in the following order: 1. *Amorum Libri III.*, a revised and abridged edition of an early series. 2. Twenty-one *Epistolæ Heroidum*. 3. The *Ars Amatoria*. 4. *Remedia Amoris*. 5. *Nux*, the remonstrance of a nut-tree against the ill-treatment it receives from the wayfarer, and even from its owner. 6. *Metamorphoseon Libri XV*. This is deservedly O.'s best-known work. It seems to have been written between the poet's fortieth and fiftieth years, and consists of all the transformations recorded in legend from the creation down to the time of Julius Cæsar, whose change into a star forms the last of the series. 7. *Pastorum Libri XII.*, the first six of which are all that remain. The poem is a Roman calendar versified, and describes the appropriate festivals and mythic legends from materials supplied by the old annalists. 8. *Tristium Libri V.*, written in elegiac metre, during the first four years of the poet's banishment. They are mainly descriptive of his miserable fate, and are full of appeals to the clemency of Augustus. 9. *Epistolarum ex Ponto Libri IV.*, also written in elegiac metre, and similar in substance to the *Tristia*. 10. *Ibis*, a short satire against some traducer of the poet's. 11. *Consolatio ad Liviam Augustam*, held spurious by some critics. 12. *Medicamina Faciei et Hælieuticon*, dubiously genuine, and of which we possess but fragments. Several of his works are entirely lost, the one best known to antiquity being *Medea*, a tragedy.

The poetical genius of O. has always been admired. A masterly facility of composition, a fancy vigorous and rarely at fault, a fine eye for colour, and a versification very musical in its flow, are the merits which have made him a favourite of poets from Milton downwards, in spite of his occasional slovenliness and falsity of thought. The best editions of O.'s entire works are Burmann's (Amsterdam, 1727), and the recent one of Merkel; while excellent commentaries on one or other of his poems have been published by Haupt, Ramsay, and Paley. A good translation of his *Metamorphoses* is that edited by Garth, with the assistance of Dryden, Addison, Congreve, and others; while special passages of the same poem have been admirably rendered by Mr D'Arcy Thompson.

OVIEDO, a pleasant and healthy city of Spain, capital of the modern province of the same name (the ancient Asturias, q.v.), stands on a plain between the rivers Nalon and Nora, 61 miles north-north-west of Leon, and 22 miles south-south-west of Gijón, on the Bay of Biscay. In the centre of the city is a handsome square, from which four principal streets, terminating in alamedas or promenades, branch off toward the north, south, east, and west, respectively. These main streets are connected by others, and all are clean and well-paved. Pure water is abundantly supplied by means of a long aqueduct, and is delivered in the city by eleven public fountains. The cathedral, a beautiful cruciform specimen of Gothic, the ornamentation of which is as rich as it is elegant, contains (in the Chapel of the Virgin) the remains of many of the early kings and princes of Asturias, and has a fine old library. Some curious, but eminently questionable relics, are to be found in the church of *San Miguel*, which is the second oldest Christian building after the Moorish

invasion. In the immediate vicinity of the city there are other churches in the early Saxon style, which are among the oldest churches in the peninsula. The convent of San Vincente, founded in 1281, has been secularised, and is now occupied by government offices, &c. Linens, woollens, hats, and firearms are manufactured. Pop. 25,460.

O. was known during the middle ages as *Civitas Episcoporum*, because many of the Spanish prelates who had been dispossessed of their sees by the Moors, took refuge here. This city, which is the see of a bishop, was twice plundered of its ecclesiastical and other treasures during the war of independence; first by Soult, and subsequently by Bonnet.

OVIEDO Y VALDES, GONZALO FER. DE, a Spanish chronicler, born at Madrid in 1478, was sent by Ferdinand to St Domingo, in the West Indies, in 1514, as intendant and inspector-general of the trade of the New World. During his long residence in St Domingo, he spent his leisure in acquiring an extensive knowledge of the West Indies; and after his return to Spain published at Toledo, in 1528, a *Summario de la Historia General y Natural de las Indias Occidentales*, which he dedicated to Charles V. He afterwards made some additions to the work, which was republished at Seville in 1535, in 21 vols., under the title of *La Historia General y Natural de las Indias Occidentales*. He left other 29 books in manuscript. A complete edition is now being prepared at Madrid. O. died at Valladolid in 1557. Besides his *History of the West Indies*, he wrote *Las Quinquagenas*, a valuable, gossiping, and anecdotal account of all the principal personages of Spain in his time, which still remains in MS. in the royal library at Madrid; and chronicles of Ferdinand, Isabella, and Charles V. A life of Cardinal Ximenes is also attributed to him.

OVIPAROUS, a term applied to animals in which reproduction takes place by eggs (*ova*). Except the mammalia, all animals are either Oviparous or Ovoviviparous (q.v.); the latter mode—which is not essentially different from the former—being comparatively rare. Even those invertebrate animals which multiply by gemmation and division, have also a true reproduction by *ova*. See EGG and REPRODUCTION.

O'VOLO, a convex moulding much used in classic architecture. See MOULDING. In Roman architecture, the ovolo is an exact quarter of a circle; in Greek architecture, the curve is sharper at the top and quirked. It is sometimes used in *Decorated Gothic*.

OVOVIVIPAROUS, a term applied to animals of which the egg is hatched within the body of the mother, so that the young is excluded alive, although the foetus has been enclosed in an egg almost to the time of parturition. It is probable that the egg is often broken in parturition itself. Some fishes are ovoviviparous, and some reptiles; also the *Mono-tremata*. The Common Lizard and the Viviparous Lizard, both natives of Britain, are illustrations of the near resemblance which may subsist between oviparous and ovoviviparous animals. The distinction is much less important than might be supposed.

O'VULE (Lat. a little egg), in Botany, the rudimentary seed. The Germen (q.v.) or ovary sometimes contains only one ovule, sometimes a small definite number, sometimes a large indefinite number. Ovules are to be regarded as metamorphosed buds. 'The single ovule contained in the ovaries of Compositæ and Grasses may be called a terminal bud, surrounded by a whorl of adhering leaves or

carpels, in the axil of one of which it is produced.'—Balfour, *Manual of Botany*. The ovule is not always contained in an ovary. In *Gymnogens* (q. v.) it is wanting, and the ovule is *naked*; but the plants possessing this character are comparatively few. The ovule is attached to the *Placenta* (q. v.), and by it to the *Carpel* (q. v.), from which it is developed. The attachment to the placenta is either immediate, when the ovule is said to be *sessile*, or by means of an umbilical cord (*funiculus*), which sometimes elongates very much after fecundation. The ovule is, in general, essentially formed of a cellular *nucleus* enclosed by two membranes, the outer of which is called the *primine*, and the inner the *secundine*. At one end of the nucleus there is an opening of both membranes—the *foramen*—through which the access of the pollen in Fecundation (q. v.) takes place. The *Chalaza* (q. v.) unites the nucleus and these membranes at the base. When the ovule is so developed that the chalaza is at the base, and the foramen at the apex, it is said to be *orthotropal* (Gr. *orthos*, straight, *tropos*, a mode). When the ovule is bent, so that the foramen is brought near to the base, it is called *campylotropal* (Gr. *kampylos*, curved). When by increasing on one side more rapidly than on the other, the ovule has its foramen close to the base, the chalaza being carried round to the opposite extremity, the ovule is *anatropal* (Gr. *ana-tropo*, to turn upside down). *Anatropal* ovules are very common. When the ovule is attached to the placenta, so that the foramen and chalaza are at opposite ends, the base being in the middle, it is called *amphitropal* (Gr. *amphi*, around).—When the ovule arises from the base of the germen, it is said to be *erect*; when it hangs from the apex of the cavity of the germen, it is *pendulous*; when it arises from the side of the germen above the base, it is *ascending*; when it hangs from the side of the germen below the apex, it is *suspended*. When two or more ovules are found, not only in the same ovary, but in the same cell, they generally exhibit different modes of attachment. See CHALAZA, EMBRYO, FECUNDATION, GERMEN, PLACENTA, SEED.

OWEN, DR JOHN, an eminent Nonconformist divine, descended from an ancient Welsh family, was the son of the Rev. Henry Owen, vicar of Stadham, in Oxfordshire, and was born at the vicarage in 1616. In his 12th year he was entered of Queens' College, Oxford, where he worked with amazing diligence; for years taking no more than four hours sleep a night. In 1635 he 'commenced' M.A. At this period (if his own statement does not exaggerate) his great ambition was to acquire celebrity either in church or state, he didn't particularly care which; and he affirms the irreligiosity and worldliness of his motives with entire frankness. Yet he appears, for all that, to have been agitated even during his student-life by the *questiones vexatæ* of ecclesiastical politics, and made himself so conspicuous by his Anti-Laudianism, that he was forced to leave Oxford. In fact, his Puritanism had become so decided, that most of his former friends had abandoned his society. The next five or six years of his life were spent, speaking generally, in a state of anxious and melancholy introspection. When the civil war finally broke out, O. was living as chaplain with Lord Lovelace of Hurley, in Berkshire. His lordship was a royalist, and went to join the king's army, whither O., who had warmly espoused the cause of the parliament, could not accompany him. About the same time, his uncle, a gentleman of property in Wales, who, having no children of his own, meant to have made O. his heir, indignant at the zealous Puritanism of his nephew, settled his estate upon another, and died without leaving him a farthing. The almost friendless

scholar now removed to London, where a casual sermon, preached by a stranger in Calamy's church, had the effect of imparting to his soul the peace he so ardently desired. In 1642, he published his *Display of Arminianism*, a work that proved very acceptable to the Puritan party, and drew upon him the favourable regards of the House of Commons. Soon after, the 'Committee for Purging the Church of Scandalous Ministers' presented him with the living of Fordham, in Essex. His ministrations were exceedingly popular, people coming from great distances to hear him preach. While residing at Fordham he married a lady named Rooke, by whom he had several children. Not long after he removed to Coggeshall, where his views of church government underwent a modification. Up to this point he had been a Presbyterian, but he now became a moderate Independent or Congregationalist. It is almost superfluous to add that the Presbyterian ministers—intolerant, dogmatical, and acrimonious to a degree that is scarcely credible—fell upon him at once for his apostasy, but failed to perturb his sober temper. At Coggeshall he wrote his *Salus Electorum, Sanguis Jesu* ('The Blood of Jesus, the Salvation of the Elect'), a work the result of seven years' study, and of which he himself said that 'he did not believe he should live to see a solid answer given to it.' His fame still increasing, he was sent for in 1646 to preach before the parliament. To his discourse, entitled *A Vision of Free Mercy*, he added an Appendix, in which he pleads for liberty of conscience in matters of religion. He was again chosen to preach before the House of Commons the day after the execution of King Charles I. (January 31, 1649), but discreetly avoided a vindication of the act. About this time Cromwell made his acquaintance, and thought so highly both of his preaching and character, that he insisted on O. accompanying him to Ireland, where the latter remained about half a year. In 1650, he went with Cromwell to Scotland, and resided in Edinburgh for several months; in 1651, the House of Commons appointed him dean of Christ Church, Oxford; and in 1652, when only in his 36th year, he was admitted vice-chancellor of the university. The manner in which he discharged his duties reflects the highest credit on the impartiality of his disposition. Though himself an Independent, and owing his honours directly to the Independent party, O. never shewed himself a partisan. Most of the vacant livings in his patronage were bestowed on Presbyterians; and Episcopalians were allowed to celebrate divine worship in their own way, nor could the vice-chancellor ever be induced to offer them the slightest molestation. While at Oxford, the 'Atlas of Independency,' as Wood grandiloquently dubs O., wrote his *Diatriba de Divina Justitia, his Doctrine of the Saints' Perseverance*, his *Vindicia Evangelica*—against Biddle (q. v.) and the Socinians—and his *Mortification of Sin in Believers*. He was one of the well-known 'tryers' appointed to 'purge' the church of 'scandalous' (i.e., royalist) 'ministers,' and in this capacity signalled himself by his friendly offices on behalf of men of learning and merit, among whom may be mentioned the celebrated Dr Edward Pococke, professor of Arabic. A coldness now appears to have sprung up between him and Cromwell. O. is said to have been opposed to what many people call the 'ambitious' designs of the Protector, and in 1657 he was succeeded as vice-chancellor of the university by Dr Conant. The year after Cromwell's death, he was ejected from his deanery, and retired to Stadham, in Oxfordshire, where he had purchased an estate, and where he formed a congregation, to which he ministered until his removal to London shortly after the Restoration.

The writings belonging to this period of retirement, if we may so call it, are, *Communion with God*; *On the Divine Original, Authority, Self-Evidencing Light and Power of the Scriptures*; *Theologoumena*, or *De Natura, Ortu, Progressu, et Studio vera Theologia*; and an uncritical, irreflexive, and unscholarly diatribe against Walton's *Polyglott*, in which the different readings of Scripture were learnedly set forth. In 1662, he published *Animadversions to Fiat Lux*, a treatise written by a Franciscan friar in the interests of Roman Catholicism. It was followed by works on *Indwelling Sin*, on the 130th Psalm, and on 'The Epistle to the Hebrews,' the last of which began to appear in 1668, and is usually reckoned O.'s *Magnum Opus*. In 1669 he published *Truth and Innocence Vindicated*, a reply to Samuel (afterwards Bishop) Parker's *Discourse on Ecclesiastical Policy*, and in 1673 became pastor of a large congregation in Leadenhall Street. His last publications of importance were a *Discourse Concerning the Holy Spirit* (1674); *Doctrine of Justification by Faith* (1677), a treatise still much admired by many; and *Christologia, or Glorious Mystery of the Person of Christ*.

O. in his later years was held in the highest esteem by many of the most influential personages in the land, such as the Earl of Orrery, the Earl of Anglesea, Lord Willoughby, Lord Berkley, Sir John Trevor. When drinking the waters at Tunbridge, even the Duke of York and Charles II. paid him particular attention, and had long conversations with him on the subject of Nonconformity. O. died at Ealing, 24th August 1683, and was buried in Bunhill Fields. His funeral was attended by no less than sixty noblemen. O. was the most voluminous, but by no means the most powerful writer among the Puritan divines. His prolix and passionless disquisitions, his dull, tedious, and exhausting arguments, his lack of subtle spiritual perception, his ponderous and lumbering style, make his writings the reverse of interesting; and one can almost pardon the irreverent criticism of Robert Hall, who is said to have pronounced them 'a continent of mud.' Yet O. deserves respect for his learning and moderation. The best edition of his works was published at Edinburgh (1856, *et seq.*).

OWEN, SIR RICHARD, was born at Lancaster, July 20, 1804. Having received his elementary education at the grammar-school of that town, he became, at the age of twenty, a student in Edinburgh University. Under the guidance of the third Monro, Alison, Jameson, and Hope in the university, and of Barclay in the outdoor school, his natural talents early developed themselves. He was an active student, and with others of kindred spirit, formed the Hunterian Society, of which he was chosen president in 1825. In 1826, he removed to London, joining the medical school of St Bartholomew's Hospital; and to the Medical Society of this institution he communicated his earliest published paper: 'An Account of the Dissection of the Parts concerned in the Aneurism, for the Cure of which Dr Stevens tied the Internal Iliac Artery,' which appeared in the *Medico-Chirurgical Transactions* for 1830. It was doubted whether so deep-seated an artery could have been reached, but he shewed that the ligature had been applied to the internal iliac, and the aneurism had in this way been obliterated.

It had been his intention to enter the navy; but when he finished his education, he accepted an appointment as assistant to Mr Clift, the Curator of the Museum of the Royal College of Surgeons, and helped him in the preparation of his catalogues of 'Pathological Specimens' (1830), 'Monsters and Malformations' (1831), but chiefly of the 'Specimens of Natural History in Spirits' (1830). He had,

about this time, the fortune to obtain a specimen of *Nautilus pompilius*, an animal almost unknown, and of great importance not only in itself, but also and chiefly because of its numerous fossil allies. The results of his careful dissection of this specimen were published in an elaborate Memoir, which at once gave him a high position amongst naturalists, for the advanced views on structure and affinities it contained.

The continued examination of Hunter's extensive collections in the College of Surgeons' Museum was his great work. This resulted in the enlargement and arrangement of the collections, and in the publication of his *Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy*, which was issued in sections during 1833-1840; of his *Paleontological Catalogue*, of which the Mammals and Birds were published in 1845, and the Reptiles and Fishes in 1854; and of his *Catalogue of Recent Osteology* (1854), in which he describes 5906 specimens. The collections, which in 1828 were contained in one small badly-lighted room, in 1856, when O.'s connection with them terminated, filled ten times the original space—three large galleries having been specially erected to contain them.

O.'s position as curator of the Hunterian Museum, to which he succeeded on the death of Clift, awakened in him a special interest in its famous founder. In 1837, he published a new edition of Hunter's *Animal Economy*, adding to it all the known published papers of its author; and giving in the preface, for the first time, a descriptive narrative of Hunter's real discoveries. He afterwards edited two volumes of *Essays and Observations on Natural History, Anatomy, &c.*, by John Hunter (1861), which had been saved from Home's unprincipled and barbarous destruction of Hunter's manuscripts, by having been transcribed by Clift, who was the last articulated apprentice of Hunter. In the preface to these volumes, O. shewed the advanced views which Hunter entertained in Geology and Paleontology.

The first appointment of O. as public lecturer was to the chair of Comparative Anatomy in St Bartholomew's Hospital in 1834. Two years afterwards, he succeeded Sir Charles Bell as Professor of Anatomy and Physiology in the College of Surgeons, and was in the same year appointed by the College as first 'Hunterian Professor.' For twenty years he continued to illustrate the recent and fossil treasures of the museum, until, in 1856, he was appointed Superintendent of the Natural History Department of the British Museum. This post he resigned on account of age in 1883.

We have not space to record even the principal of O.'s numerous published papers. His earliest communications to the Royal Society were papers on the generation of the ornithorhynchus and of the kangaroo. In numerous Memoirs between 1835 and 1862, he expounded the structure and affinities of the higher quadrumana; and in these and other papers, he proposed the use of the brain-structure, as an important element in classification. It has been objected, that the particular parts to which he referred in characterising his highest class, are found in the lower classes; but the objectors forget that he does not use the existence of the parts as his characters, but only their remarkable development. A similar objection may be urged against every system of classification, for no decided line can be drawn around any group, the whole animal world being united by a graduation of structure.

His exposition of the recent and fossil birds of New Zealand is well known. He first published two elaborate papers on the anatomy of the Apteryx,

and then followed at intervals seven or eight monographs on the gigantic struthious Birds which once existed in these distant islands. His descriptions and restorations of extinct animals are perhaps the most important of all his labours. He has published a monograph of the British Fossil Mammalia and Birds, and six parts of an elaborate systematic history of British fossil Reptiles. In describing the fragmentary fossil relics brought home by Darwin from South America, he established many remarkable forms from very scanty materials, and shewed that there existed in America, during the Tertiary period, a mammalian Fauna, the individuals of which were, for the most part, of gigantic size, yet similar in type to the existing animals of that continent. Subsequently, he clearly expounded the various genera of huge sloths from the same region, whose remains were previously confounded or misunderstood. A series of fossils from Australia revealed to him a remarkable group of gigantic marsupials, resembling in type the present tenants of that island-continent. He was the first to expound the structure and affinities of the singular long-tailed bird from Solenhofen. See his well-known *Paleontology* (1861). Amongst his more recent works in this field are *The Fossil Reptilia of South Africa* (1876); *On the Fossil Mammals of Australia, and on the Extinct Marsupials of England* (1877); and *On the Extinct Wingless Birds of New Zealand* (1879).

His great work on the microscopic structure of the teeth must be named. The *Odontography*, published in 1840—1845, contains descriptions and exquisite drawings of the minute structure of a very extensive series of the teeth of every class of animals, and forms an immense store-house of information alike to the anatomist and the geologist.

He has published original papers on every branch of the animal kingdom, living and fossil; and it has been justly said of him, that 'from the sponge to man, he has thrown light over every subject he has touched.' Some idea of the magnitude of his labours may be formed from the fact, that his published productions amount to more than 360 different papers and works, many of them being of the most voluminous and laborious character.

O., in 1835, married the only daughter of Clift, his colleague at the College of Surgeons. In 1858, he resumed his position as Fullerian Professor of Physiology in the Royal Institution of Britain, which, some 20 years before, he had filled for two sessions; and in the following year, he was appointed Reader Lecturer by the University of Cambridge, but has now resigned these offices. He is a Fellow and active member of most of the metropolitan scientific societies, one of the eight foreign associates of the Institute of France, and an honorary member of many foreign societies. From France he also received the order of the Legion of Honour; from Prussia, the *Ordre pour le Mérite*; and from Italy, the Order of St Maurice and St Lazare. He was made a companion of the Bath in 1873, and a K.C.B. in 1883.

OWEN, ROBERT, a social theorist and schemer, was born on the 14th of May 1771, at Newton, in Montgomeryshire. He does not appear to have had any more than a merely commercial education to fit him for common business. The point from which his peculiar destiny in life may be said to have started, was his marriage in 1799 to the daughter of David Dale, the owner of the celebrated cotton mills at New Lanark, on the Clyde. This establishment was very successful as a money speculation, and it is curious that Jeremy Bentham made a small fortune by investing in it. Mr Dale was known to be a thorough man of business, but whether O., by his peculiar faculties for organisation, contributed to

the prosperity of the establishment in its early stages, is a doubtful question. It is certain that as his larger schemes developed themselves, he was felt to be a dangerous partner in a good business, and he was gradually elbowed out of any voice in the management, and he finally disposed of his share in the property.

It should be remembered, however, of a man whose life will go down to posterity as one long absurdity, that in his connection with New Lanark Mills he did real practical good on a scale by no means limited. He was naturally active and interfering, and being a humane man, it struck him that much degradation, vice, and suffering arose from the disorganised manner in which the progress of machinery and manufactures was huddling the manufacturing population together. He introduced into the New Lanark community education, sanitary reform, and various civilising agencies, which philanthropists at the present day are but imperfectly accomplishing in the great manufacturing districts.

A factory was, however, far too limited a sphere for his ambition. He wanted to organise the world; and that there might be no want of an excuse for his intervention, he set about proving that it was in all its institutions—the prevailing religion included—in as wretched a condition as any dirty demoralised manufacturing village. Such was the scheme with which he came out on the astonished world in 1816, in his *New Views of Society, or Essays on the Formation of the Human Character*; and he continued, in books, pamphlets, lectures, and other available forms, to keep up the stream of excitation till it was stopped by his death. He had at least three grand opportunities of setting up limited communities on his own principles—one at Romney, in America; a second at Orbiston, in Lanarkshire; the third at Harmony Hall, in Hampshire, so lately as the year 1844. They were, of course, all failures, and O. attributed their failure to their not being sufficiently perfected on his principles. His life was a remarkable phenomenon, from the preternatural sanguineness of temperament which, in the face of failures, and a world ever growing more hostile, made him believe to the last that all his projects were just on the eve of success. In the revolution of 1848 he went to Paris, with hopes of course on the highest stretch; but his voice was not loud enough to be heard in that great turmoil. He appeared at the meeting of the Social Science Association at Liverpool in the autumn of 1858, with all his schemes as fresh as ever. He died a few weeks afterwards, on 17th November 1858. A life of O. by A. J. Booth appeared in 1869 (Trübner).

OWENS COLLEGE, Manchester, was founded in 1851 under the will of John Owens, a Manchester merchant, who left £100,000 for the instruction of young men 'in such branches of science and learning as were then and might be thereafter usually taught in English universities.' It was from the beginning a successful institution; and the college has now a staff of about 60 professors and lecturers—some of them amongst the foremost men in their respective subjects—in the two departments of Arts, Science, and Law, and of Medicine. There are between 20 and 30 scholarships and prizes, and a valuable fellowship. The handsome new college buildings, erected since 1870, were estimated to cost £120,000.

In 1880, a charter was granted to a new VICTORIA UNIVERSITY, of which O. C. was constituted a college. Other colleges (such as the Yorkshire College at Leeds) may be admitted on certain conditions. The University, which will be ultimately a federation of colleges, has its seat in Manchester; and, unlike London University, is at once a teaching and

examining body, exacting from intending graduates attendance on a defined course of study. Every college admitted to the federation must have a sufficient teaching staff and curriculum, must be established on a sound basis, and must be under the control of its own governing body. The University Court has power to exclude any college that has ceased to be efficient.

OWL, a numerous and extremely well-defined group of birds, constituting the family *Strigidae*, the whole of the nocturnal section of Birds of Prey. The owls are easily distinguished by the large size of their heads, and by their great eyes, directed forwards, and surrounded with more or less perfect discs of feathers radiating outwards, whilst the small hooked bill is half concealed by the feathers of these discs, and by bristly feathers which grow at its base. The bill is curved almost from its base; the upper mandible not notched, but much hooked at the tip. The claws are sharp and curved, but, like the bill, less powerful than in the *Falconidae*. The outer toe is generally reversible at pleasure, so that the toes can be opposed two and two, to give greater security of grasp. The wings, although generally long, are less adapted for rapid and sustained flight than those of the diurnal birds of prey, and the bony framework by which they are supported, and the muscles which move them, are less powerful; the owls in general taking their prey, not by pursuit, but by surprise, to which there is a beautiful adaptation in the softness of their plumage, and their consequently noiseless flight; the feathers even of the wings being downy, and not offering a firm resisting surface to the air, as in falcons. The soft and loose plumage adds much to the apparent size of the body, and also of the head; but the head owes its really large size to large cavities in the skull between its outer and inner tables or bony layers, which cavities communicate with the ear, and are supposed to add to the acuteness of the sense of hearing. This sense is certainly very acute, and the ear is, in many of the species, very large. It is furnished with an external conch, which is found in no other birds. It is, however, concealed by the feathers, being situated on the outside of the disc which surrounds the eye; but the feathers immediately surrounding the ear are arranged in a kind of cone, serving a purpose like that of an ear-trumpet. In some species, the ear is furnished with a remarkable lid or operculum, which the bird has the power of opening and shutting at pleasure. The disc which surrounds the eye serves to collect rays of light and throw them on the pupil; and owls can see well in twilight or moonlight, but are generally incapable of sustaining the glare of day, many of them becoming quite bewildered when exposed to it, and evidently suffering pain, which they instinctively seek to relieve by frequent motion of the third eyelid or nictitating membrane of the eye. The legs and feet of owls are feathered to the toes, and in many species even to the claws.

The digestive organs much resemble those of the *Falconidae*, but there is no crop, and the stomach is more muscular. The gullet is very wide throughout, and owls swallow their prey either entire or in very large morsels. The largest species feed on hares, fawns, the largest gallinaceous birds, &c.; others on small mammalia, reptiles, birds, and sometimes fishes; some feed partly or chiefly on large insects.

Some of the owls have the discs of the face imperfect above the eyes, the whole aspect somewhat approaching to that of falcons; the conchs of the ears small, and the habits less nocturnal than the rest of this family. These constitute one of the three generally received divisions in which the species are

arranged. Another division, with more perfect discs around the eyes, is characterised by the presence of two feathery tufts on the head, popularly called horns, or ears, and sometimes egrets or aigrettes. The third division is destitute of these tufts, the discs of the face are perfect, and the ears are very large. On these distinctions, and on the feathered or unfeathered toes, and other points not of great importance, are founded the genera into which the Linnean genus *Strix* has been broken down by recent ornithologists. See, for example, the characters of *Bubo* in the article EAGLE OWL.

Owls are found in all parts of the world, and in all climates. Ten species are reckoned as natives of the British Islands, some of which, however, are very rare, and about fifteen are natives of Europe. Some of the species have a very wide geographical range. One of the most plentiful British species is the WHITE OWL, or BARN OWL, or SCREECH OWL (*Strix flammea*), one of those having perfect discs around the eyes, and no aigrettes. It is about fourteen inches in its whole length. The tail is, as in most of the owls, rather short and rounded; the

1. Great or Eagle Owl (*Bubo maximus*); 2. Snowy Owl (*Nyctes nives*); 3. Virginian Bared Owl (*Bubo virginianus*); 4. White or Barn Owl (*Strix flammea*); 5. Long-eared Owl (*Otus vulgaris*); 6. Foot of Snowy Owl.

wings reach rather beyond the tail. The toes are not feathered. The head and upper parts are of a pale orange colour, marked by a multitude of small, scattered chestnut-coloured spots, and gray and brown zig-zag lines; the face and throat white. This owl very generally frequents old buildings and outhouses. It destroys great numbers of rats and mice, and deserves the protection of the farmer. The voracity of owls is wonderful, and they kill, if possible, more than they need, storing it up for future use. The barn owl is easily tamed if taken young. When irritated, it has, like some other—perhaps all—owls, a habit of hissing and snapping its mandibles together. It almost never leaves its retreat by day, unless driven out; and when this is the case, all the little birds of the neighbourhood congregate about it as an enemy which may then be safely annoyed, and the grimaces of the poor owl, blinded by the too strong light, are very grotesque and amusing. This species has been said to be an inhabitant of almost all parts of the world, but there is reason to think that similar species have been confounded.—The TAWNY OWL, BROWN OWL, or IVY OWL (*Strix*, or *Syrnium*, *stridula* or *aluco*) is another of the most common British owls,

a species about the size of the barn owl, or rather larger, with rather longer tail, and comparatively short wings, the feet feathered to the claws; the upper parts mostly ash-gray mottled with brown, the under parts grayish-white and mottled.—The LONG-EARED OWL (*Strix otus*, or *Otus vulgaris*) and the SHORT-EARED OWL (*S.* or *O. brachyotus*), species with aigrettes, are not unfrequent British birds. The EAGLE OWL (*q. v.*) occurs, but is rare.—Of the species with imperfect discs around the eyes and more falcon-like aspect, the most interesting in the British fauna is the SNOWY OWL (*Strix*, or *Surnia, nyctea*), the *Harfang* of the Swedes, a species occasionally seen in the Shetland Islands, and very rarely in more southern regions in winter, but well known in all the very northern parts of the world. It is from 22 to 27 inches in length, feeds on every kind of animal food which it can obtain, and has white plumage spotted and barred with brown, the legs densely feathered to the claws.—Of owls not natives of Britain, one of the most interesting is the BURROWING OWL (*Strix*, or *Athene, cucularia*), a North American species, which, when necessary, excavates a burrow for itself, but prefers to take possession of those of the marmot, called the PRAIRIE DOG (*q. v.*). It is not the only species of owl which inhabits holes in the ground.—The BOOBOOK or BOOKBOOK of Australia (*Strix*, or *Noctua, Boo-book*) is a species of owl, which frequently repeats during the night the cry represented by its name, as if it were a nocturnal cuckoo. Some of the species of owl are small birds; among the rarer British species are one of 8½ inches, and one scarcely more than 7 inches long. Some owls are at least partially birds of passage, of which, among British species, the short-eared owl is an example.

OWLGLASS (Ger. EULENSPIEGEL), TYLL, the prototype of all the knavish 'fools' of later time, is said to have been born in the village of Kneittingen, in Brunswick. His father was called Klaus Eulenspiegel, and his mother Anna Wortbeck. In youth, we are told, he wandered out into the world, and played all manner of tricks on the people whom he met with. His tomb is shewn at Mölln, about four leagues from Lübeck, where tradition makes him die about 1350; but the inhabitants of Damme, in Belgium, also boast of having his bones in their churchyard, and place his death in 1301, so that several critics regard Eulenspiegel as an altogether imaginary person, a mere *nominis umbra* affixed to a cycle of medieval tricks and adventures. The opinion, however, considered most probable is that Eulenspiegel is not a myth, but that there were two historical individuals of that name, father and son, of whom the former died at Damme, and the latter at Mölln. The stories that circulate in Germany under Eulenspiegel's name were not collected, as the book containing them itself informs us, till after Eulenspiegel's death, and without doubt were originally written in the Low German tongue; from Low German, they were translated into High German by the Franciscan Thom. Murner, and this translation was followed in all the old High German editions of the work. At a later period, it underwent considerable alterations, at the hands of both Protestants and Catholics, who made it a vehicle for the expression of their own likings and dislikings. The oldest known edition is that printed at Strasburg in 1519. The verdict of modern times has been unfavourable, not only to the æsthetic, but to the moral value of the book; yet although indecencies may be found abundantly in it, they may perhaps in large measure be attributed to the age in which Eulenspiegel or the author of Eulenspiegel lived. For centuries it has been a favourite people's book, not only in Germany, but in many other countries.

Translations of it exist in Bohemian, Polish, Italian, English (as a *Miracle Play*), Dutch, Danish, French, and Latin; it has been frequently imitated, and reprinted times without number down to the most recent years. Max Müller, in his *Lectures on the Science of Language* points out that Eulenspiegel is the origin of the French word *espègle*, waggish. When the stories about Eulenspiegel were translated into French, he was called Ulespiegle, 'which name contracted afterwards into *Espègle*, became a general name for every wag.'

OWNERSHIP is not a legal term, though it is used frequently in law to denote the highest degree or kind of property which one can have in anything. Owner is often used in this sense as contradistinguished from an occupier, who has only a temporary interest in the property. Thus a freeholder, or one who holds a freehold estate in land, is an owner; though, in common parlance, it is not unusual also to describe as owner any one who has a long lease of the property. When a person is owner in fee of land, he has certain rights more or less absolute as incidental thereto; for example, he may build on his land as high as he pleases, subject only to doing no direct injury to his neighbour, such as darkening his windows; and he may dig as deep as he pleases, or, as it is said, to the centre of the earth. There are certain things which are said to be incapable of ownership, such as the air, the sea, and the water of navigable rivers, as to each of which every individual member of the public has the right merely of using it, but no one has the ownership—i. e., the exclusive right of property as well as possession thereof. As to things wild, such as birds, beasts, fishes, the rule is that he who first catches the animal becomes the owner thereof, and acquires such a property in it, that any one who takes it from him against his will commits larceny. But though the person who first catches a wild animal is entitled to it, penalties are sometimes imposed upon the person catching it, as to which see GAME, POACHING. In regard to lost property—i. e., property which had once been appropriated and possessed by some one, but who has casually lost or abandoned it—the rule is that he who finds it is entitled to keep it, provided at the time of finding it he had no means of ascertaining the owner. But the true owner, if he discover and can identify the property, can always in general reclaim it from the finder. See LOST PROPERTY.

OX (*Bos taurus*), a ruminant quadruped of the family *Bovidae* (*q. v.*), the most useful to man of all domesticated animals. The species is distinguished by a flat forehead, longer than broad; and by smooth and round tapering horns, rising from the extremities of the frontal ridge. But among the many varieties or breeds which exist, there are great diversities in the length and curvature of the horns, and some are hornless. It is probable that the ox is a native both of Asia and of Europe, perhaps also of Africa; and not improbable that it may have been domesticated at different times and in different countries. It cannot be confidently asserted that it now exists anywhere in a truly wild state; wild oxen are nowhere so abundant as on the pampas or great grassy plains of South America, where it is certain that they are not indigenous; and it is not impossible that the wild oxen still existing in the parks of a few noblemen in Britain may be also descended from domesticated animals. Whether or not the URUS, described by ancient authors as an inhabitant of Central Europe, was the original of the domestic ox, will be considered in the article URUS. The very early domestication of the ox is attested by the mention made of it in the writings of Moses,

and by the worship of it in Egypt, which the Israelites imitated in making their golden calf at Mount Sinai. Yet oxen do not appear to have formed any part of the wealth of the patriarchs. The ox was probably used as a beast of burden or draught before it was valued for its milk. It is mentioned by Cæsar as a principal part of the wealth of the Britons at the time of the Roman invasion.

The ox is more frequently employed as a beast of burden and of draught in some parts of the continent of Europe than in Britain. From the earliest historic times, the horse has been more generally thus employed in Britain, and has now almost entirely superseded the ox. The gait of the ox is slow and plodding, but its strength enables it to perform a great amount of work, and it is not easily exhausted. It needs, however, intervals of rest inconvenient for the farmer; and it is not capable of exertion at all equal to that of the horse on any occasion of emergency.—The ox is chiefly valuable for its flesh and its milk; but almost every part of the animal is useful—the fat, skin, hair, horns, intestines.

The period of gestation of the ox is nine months, or 270 days. It rarely produces more than one calf at a birth. It attains maturity in two or three years, becomes evidently aged at ten, and seldom lives more than fourteen. Cows are seldom kept for the dairy after they are seven or eight years old, as after that age they yield less milk and of inferior quality. Modern husbandry has also found means to fatten cattle for the market at an earlier age than was formerly usual; and although the beef is not quite so good in quality, the profit is great, both to the farmer and to the community, through the increased productiveness of the land.

The ox is gregarious, and where circumstances permit, as in the South American plains, associates in very large herds. Herds of oxen defend themselves with great vigour against the large feline animals and other assailants, the younger and weaker animals being placed in the middle, whilst the bulls in the outer rank confront the adversary with their horns.

The varieties or breeds differ very much in size. Among those which occur in the British Islands, the Shetland breed is not much larger than a calf of some of the others. Some of the breeds of the torrid zone are also very small; but the fatty hump on the back may probably be regarded as indicating a connection with the Indian ox or Zebu (q. v.), which, although it has been generally regarded as a variety of the common ox, is perhaps a distinct species.—The 'wild ox,' now existing only in a few parks, as at Chillingham and Hamilton, seems, whatever its origin, to have been formerly an inhabitant of many forest districts in Britain, particularly in the north of England and south of Scotland. The Chillingham wild oxen are of a creamy white colour, much smaller than many of the domestic breeds, of a graceful form, with sharp horns, which are not very long, and not very much curved. The uniform white colour is to be ascribed to the care taken to destroy every calf which is not perfect in this respect. The habits of these wild oxen are very similar to those of the domestic races.

—The *West Highland* breed, or *Kyloe*, differs very little from the Chillingham or Hamilton wild ox, except in being generally black. It has short muscular limbs, a wide and deep chest, well-arched ribs, and a straight back; the horns are often somewhat long; the muzzle is short but not broad; the skin is closely covered with shaggy hair. The milk is very rich, but the quantity is so small, that this breed is very unsuitable for dairy farming. The beef,

however, is of the finest quality; and great numbers of cattle, reared in the Highlands and Hebrides, are annually conveyed to other parts of the country, to be fattened on rich pastures. The breed is a very hardy one, and peculiarly suited to the region in which it prevails.—The *Galloway* breed is very like the preceding, but larger and destitute of horns; and many cattle reared in the hilly parts of Galloway are fattened on English pastures for the London market.—The *Pembroke* and other Welsh breeds are not unlike the West Highland; but the cows yield milk more abundantly.—The diminutive *Shetland* breed is very hardy, and is celebrated for the fine quality of its beef. The Shetland ox is easily fattened, even on scanty pasturage. The milk which the cows yield is also remarkably abundant in proportion to their small size.—The *Ayrshire* breed is particularly celebrated for the abundance and excellence of its milk, but the beef is of inferior quality, and the animal is not easily fattened. Great care has been bestowed on this breed in Ayrshire and neighbouring counties, where dairy farming is much practised. The horns are smaller than those of the West Highland breed, the hair much smoother, and the colour chiefly brownish-red, with large patches of white.—The *Alderney* breed much resembles the Ayrshire, but the milk is comparatively small in quantity, and remarkable for the richness of the cream, on which account Alderney cows are often kept for the supply of private dairies. The milk of an Alderney cow, mixed with that of a dozen other cows, will sensibly improve the quality of the butter. But this breed is worthless for the purposes of the grazier.—The *Suffolk Dun* is a *polled* or hornless breed, of clumsy form, and of little value to the grazier, but yielding a very large quantity of milk, on which account Suffolk has long been celebrated for its dairy produce.—The *North Devon* is a pretty large breed, with rather short horns, very muscular and powerful, and also very gentle and docile, so that it is particularly adapted for draught; and much agricultural labour is still performed in Devonshire by teams of oxen of this breed. The North Devon breed, however, is surpassed by others, both for the purposes of the dairy farmer and of the grazier.—The *Hereford* breed, of stouter form than the Ayrshire, but

Bull (short-horn).

in some respects not unlike it, has long been in great repute both for its beef and its milk; but in the districts where it once prevailed, it is now giving place to the *Short-horn* breed, one of the new breeds which are the result of care and attention. The Short-horn breed, so called because the horns are shorter than in almost any other, originated about the beginning of the 19th c. on the banks of the Tees, and has spread very widely both

in England and in Scotland, in the districts of richest pasturage. The colour varies from pure white to bright red; the head is short and very broad; the chest is wide, deep, and projecting; the fore-legs are short, the back straight, and not very long, the 'barrel' full. The ease with which oxen of this breed are fattened is one of its great recommendations. The beef is also of excellent quality. For dairy purposes, the Short-horn is surpassed by some other breeds; but a cross between a Short-horn bull and an Ayrshire cow is found useful both for beef and milk. The Short-horn breed is now cherished in Britain with peculiar care; genealogies are registered, and prodigious prices are given for first-rate animals. It is also in great esteem in many parts of the continent of Europe, and in America.—The *Long-horn* breed, long prevalent in the midland counties of England, and still prevalent in Ireland, was brought to great perfection by Bakewell, one of the first to shew what could be done in the improvement of cattle; but is rapidly giving place to the Short-horn, by which it is much excelled. The length of the horns in this breed is very remarkable.

Of foreign races of oxen, one of the most notable, on account of its large size, is that in possession of the Kalmuck Tartars; another is that prevalent in the Roman states, generally of a bluish-ash colour, with remarkably large and spreading horns. A large white breed was long kept in Egypt; and a similar breed, without the hump characteristic of the Indian Ox, is found in South Africa, where, however, it has become partially intermixed with European breeds. Oxen are much employed by the Kaffirs as beasts of burden; they were also formerly trained by the Hottentots to aid them in battle. Peter Kolben, in his account of the Cape of Good Hope, written in 1705, gives an interesting description of these trained fighting oxen, which, he says, are called *Backeleyers*. 'In the wars of the Hottentots with one another,' he says, 'these backeleyers make very terrible impressions. They gore, and kick, and trample to death with incredible fury.' He ascribes to them also great docility, and states that they know every inhabitant of the kraal, and are perfectly inoffensive towards them, but ready to run with fury at strangers. The readiness with which the draught oxen of South Africa observe the words of the driver, is said to be almost, if not quite, equal to that of the dog. In the training of them, however, severe measures are often requisite, and particularly by a hooked stick inserted through the cartilage which separates the nostrils, as bulls are *ringed* when sent to exhibitions of cattle in Britain. Trained oxen are also employed in the training of their younger fellows. In some parts of Africa the ox is used for riding as well as for draught. The horns, which are very long, are split into ribbons, or curved in various directions, to prevent their points from coming in contact, by any accident, with the person of the rider. The pace of the ox scarcely exceeds four or five miles an hour.

A very remarkable conformation of skull occurs in some of the herds of South American oxen, the bones of the nose and the jaw-bones being very much shortened; yet there is no question that this is a mere accidental variation, which has become perpetuated as one of race. Importance has been attached to it in the discussions regarding *species*.

The cow has been for ages tended by man on account of the agreeable and highly nutritious fluid which is obtained from it. Milk is manufactured into cheese and butter, which are capable of being preserved for a considerable time. The processes by which these are obtained are

described under the article DAIRY. Cows, under our modern systems of agriculture, are selected either for their properties of giving large quantities of milk, or for raising stock which are well suited for grazing and fattening. For milking properties, the Ayrshire breed stands undoubtedly at the head of the list. In comparison with some of the other breeds, the Ayrshire is rather deficient in size, with the flesh spread thinly over its body. In the male animals these characteristics are all the more prominent, and for this reason the breed is not much liked by graziers. It is capable, however, of thriving on secondary or even inferior pastures. Wherever, therefore, it is found most profitable to follow dairy husbandry in Scotland, the Ayrshire cow is preferred. A considerable variety of breeds are cultivated both for milking and grazing in the western parts of England, the principal of which are the Herefords and Devons. In the eastern counties, again, where arable culture and the rearing and feeding of cattle are chiefly followed, the Ayrshire gives place to the Aberdeen, the Angus, and the Teeswater. The cow is there selected for its massive and square-built frame, soft skin, and meat-producing qualities. For more than a century vast care has been bestowed on the improvement of the short-horns. In this breed the pedigrees of the sire and the dam are traced back for many generations, and purity of blood is quite essential in herds of any pretensions. The large sums which particular cows and bulls of this breed realise, attest the value which modern breeders set upon animals which are considered to approach perfection in their form and style. In no department of British agriculture are the results of care and attention more strongly marked than in the noble figure of the short-horned cow or bull.

The rearing and fattening of the ox is one of the most important branches of agriculture. Since the prices of butcher-meat have become so much higher relatively to corn in this country, the breeding and feeding of cattle have received a great impetus. Fifty years ago, many of our old breeds of cattle were kept till they were four or five years old before they were sent fat to the butcher. The demand for meat was so limited then in the north, that most of the cattle were sent south lean, to be fattened on the pastures and turnips of the eastern counties of England. The introduction of steam-shipping, followed by railways, has given the Scotch breeder and feeder great facilities for disposing of fatted cattle, and now there are no lean cattle sent to the south. Indeed, the extension of green crops in Scotland has been so great, that large numbers of lean cattle are imported from England, as well as Ireland, to be fed in the stalls and courts during winter. This applies to the arable districts, where the land does not remain more than one year in grass. In Aberdeenshire, where the land rests from three to four years in grass, more cattle are bred and turned out fat, which is by far the most profitable system, seeing the breeder often gets a larger share of the profits than the feeder. The short-horned blood is in great request to cross with the native breeds, rendering the progeny much easier fattened, as well as causing them to grow to a larger size. It is now the most approved method to feed the calf from the time it is dropped till it is sent to the butcher. Oil-cake is generally considered the best and most healthy auxiliary food for stock, whether old or young. In the pastoral districts of England, where little of the land is cultivated, the rearing of cattle to be sent into the arable districts is carried out. The young animals are fed with hay in winter instead of straw and turnips. Large numbers of cattle are fattened on turnips and

mangold in winter in Norfolk and eastern counties. Large allowances of cake and corn are there given in addition to the roots.

OXALIC ACID ($C_2O_4 \cdot 2HO + 4Aq$) occurs in colourless, transparent, oblique, rhombic prisms, which have an intensely sour taste, and are soluble in nine parts of cold water, and much more freely in boiling water. When heated to 212° , the crystals lose their four equivalents (or 28.5 per cent.) of water, and the residue, consisting of the hydrated acid ($C_2O_4 \cdot 2HO$), becomes opaque; these two equivalents of water contained in the hydrated acid, cannot be expelled by mere heat, although they can be displaced by an equivalent amount of a metallic oxide. When the crystallised acid is rapidly heated to about 300° , it is decomposed into a final mixture of carbonic acid, carbonic oxide, and water; formic acid being produced and again decomposed in the process.

and formic acid when heated yields $2HO + 2CO$. When warmed with strong sulphuric acid, it is decomposed into equal volumes of carbonic acid and carbonic oxide gases, and into water; according to the equation:

This reaction affords one of the best means of obtaining carbonic oxide for use in the laboratory. Oxidising agents, such as binoxide of manganese, peroxide of lead, nitric acid, &c., convert oxalic into carbonic acid, and on this property is based a good method of determining the commercial value of the black oxide of manganese.

Oxalic acid is one of the most powerful of the organic acids, and expels carbonic acid and many other acids from their salts. The acid itself, and its soluble salts, are poisonous. This acid is very widely diffused throughout the vegetable kingdom. Sometimes it occurs in a free state (as in *Boletus sulphureus*), but much more frequently as a salt, either of potash, as in the different species of *Oxalis* (from which genus the acid was originally obtained and derives its name), and of *Rumex*; or of soda, as in various species of *Salicornia* and *Salsola*; or of lime, as in Rhubarb and many Lichens. In the animal kingdom, it never occurs except in minute quantity and in combination with lime. Oxalate of lime is found in a crystalline shape, both in healthy and morbid urine. In the latter, it constitutes the leading symptom of the affection termed OXALURIA (q. v.), while in the former it occurs after the use of wines and beer containing much carbonic acid, of sorrel, rhubarb-stalks, &c., and after the administration of the alkaline bicarbonates. It is the constituent of the urinary calculus, known from its rough exterior as the mulberry calculus. Crystals of oxalate of lime have also been found in the mucus of the gall-bladder, on the mucous membrane of the impregnated uterus, and in morbid blood. They have likewise been detected in the biliary vessels and excrements of caterpillars. In the mineral kingdom these crystals have been detected in association with crystals of calcareous spar.

Oxalic acid is produced by the action of either hydrate of potash or of nitric acid upon most organic compounds of natural occurrence. Its most

common mode of preparation is by the oxidation of starch or sugar by nitric acid. The organic compound and the nitric acid are heated in a flask till all effervescence has ceased, after which the solution is evaporated, and the oxalic acid separates in crystals on cooling.

This acid forms three series of salts, viz., neutral, acid, and super-acid, which, if M represents the metal entering into the salt, may be represented by the formulae:

the last being a compound of the acid salt and the acid. Oxalate of lime ($2CaO, C_2O_4 + 4Aq$) and ordinary (neutral) oxalate of ammonia ($2NH_4O, C_2O_4 + 2Aq$) are examples of the first; binoxalate of potash, or salt of sorrel ($KO, HO, C_2O_4 + 2Aq$), is an example of the second; while the salt usually termed quadroxalate of potash ($KO, 3HO, 2C_2O_4 + 4Aq$) is an example of the third class. Of the numerous oxalates, the most important are the oxalate of lime (in consequence of its physiological and pathological relations); the neutral oxalate of ammonia, which is the best test for the detection of lime in solution (in consequence of the extreme insolubility of the resulting oxalate of lime); and the acid oxalate of potash, which is contained in the juices of *oxalis* and *rumex*, and is employed in various manufacturing processes.

The best test for this acid is the production of a white precipitate (of oxalate of lime), on the addition of any soluble salt of calcium. The precipitate is insoluble in water, in solution of potash, and in acetic acid, but dissolves in the mineral acids. A solution of nitrate of silver also gives a white precipitate of oxalate of silver, which explodes when heated.

In consequence of its employment in cotton printing, bleaching straw, &c., oxalic acid is more accessible to the general public than many other poisons; and on this account instances of suicide from the swallowing of this acid are by no means uncommon. Cases of accidental poisoning, moreover, sometimes occur by its being sold by mistake for Epsom salts. Large doses destroy life very rapidly. Dr A. Taylor mentions a case in which a man died in 20 minutes after taking two ounces of the acid. Dr Christison records a case in which an ounce killed a girl in 30 minutes, and another case in which the same quantity destroyed life in ten minutes; and, as a general rule (liable to exceptions), when the dose is half an ounce or upwards, death commonly takes place within the hour. The symptoms are a hot or burning acid taste, with a sense of constriction or suffocation; vomiting, great pain in the region of the stomach, convulsions, cold perspirations and general collapse speedily follow; and respiration shortly before death becomes slow and spasmodic. With the view of converting the free acid in the stomach into an insoluble and inert salt, chalk, whiting, or lime-water, with full draughts of milk, should be administered with the least possible delay. Salt of sorrel is almost as poisonous as the pure acid.

OXALIDEÆ, or OXALIDEÆ, a natural order of exogenous plants, allied to *Geraniaceæ*; including herbaceous plants, shrubs, and trees; with generally compound alternate leaves; calyx of five equal persistent sepals; corolla of five equal unguiculate petals, spirally twisted in bud; ten stamens, usually more or less united by the filaments, in two rows; the ovary usually 5-celled, with five styles; the fruit a capsule opening by as many or twice as many valves as it has cells, or

more rarely a berry; the seeds few, attached to the axis. There are upwards of 300 known species, natives of warm and temperate climates. They are particularly abundant in North America and at the Cape of Good Hope. The flora of Britain includes only two small species of *Oxalis*. An acid juice is very characteristic of this order. Some of the tropical species produce agreeable acid fruits, as the Carambola (q. v.).—The genus *Oxalis* has a capsular fruit, and the seeds have an elastic integument, which at last bursts open and projects the seed to a distance. The species are mostly herbaceous plants with ternate or digitate—rarely simple or pinnate—leaves; a few are shrubs. The stems and leaves generally contain a notable quantity of *Binoxalate of Potash*, and have therefore a sour taste.—The COMMON WOOD-SORREL (*O. acetosella*), very abundant in shady woods and groves in Britain and most parts of Europe, a native also of North America, is a beautiful little plant, often covering the ground with its green leaves, amidst which the white or slightly roseate flowers appear. Its leaves all grow from the root, a long leaf-stalk bearing three obovate leaflets; the scape bears a single flower. There is a subterranean scaly root-stock. On account of their grateful acid taste, the leaves are used in salads and sauces. The plant is extremely abundant in Lapland, and is much used by the Laplanders. It is antiscorbutic and refrigerant, and an infusion of it is a grateful drink in fevers. *Binoxalate of potash* is obtained from the leaves by expressing the juice, and crystallising; and is sold not only under the name of *Salt of Sorrel*, but also of *Essential Salt of Lemons*, and is used for extracting spots, and particularly iron-marks, from linen, and for other purposes. Much of it is now, however, obtained from a very different source. See OXALIC ACID.—*O. corniculata*, rare in Britain, and almost confined to the south of England, but a plant of very extensive distribution, being found in Europe, North America, India, Japan, and some of the African islands, has a branched stem, with decumbent branches, leaves very similar to those of the common wood-sorrel, and yellow flowers. Its properties agree with those of the common wood-sorrel. Many other species much resemble these in their general appearance and properties. Some of the species exhibit an irritability like that of the Sensitive Plant; generally, as in the two British species, in a slight degree, and notably only in hot sunshine, but *O. sensitiva*, an East Indian species, with pinnate leaves, possesses this property in a high degree. Some species of *Oxalis*, as *O. cernua*, a native of South Africa, are remarkable for producing large bulbils in the axils of the lower leaves. Several species have tuberous roots, and are cultivated on account of their tubers; as *O. crenata* and *O. tuberosa*, natives of Peru and Bolivia, where they are much esteemed, and both receive the name *Oca*. The tubers, when cooked, become mealy like potatoes. They have a slightly acid taste. *O. crenata* has been cultivated in gardens in Britain for about thirty years, but continues to be almost exclusively an object of curiosity, being too tender for the climate, and its produce very inconsiderable in quantity. Its tubers are yellow, in size and shape like small potatoes. The succulent stalks of the leaves abound in a pleasant acid juice, and make excellent tarts and preserves. *O. tuberosa* produces numerous small tubers. The Bolivians often expose them for a long time to the sun, by which they lose their acidity, become saccharine, and acquire a taste and consistence like dried figs. *O. Deppei* is a Mexican species, with a root somewhat like a small parsnip, quite free of acidity. It is much cultivated in its native country, and succeeds well in the

southern parts of England. *O. tetraphylla* and *O. crassicaulis*, natives of Mexico, and *O. enneaphylla*, a native of the Falkland Islands, also have eatable roots. Many species of *Oxalis* are much esteemed as ornaments of gardens and green-houses.

OXALURIA, or THE OXALIC ACID DIATHESIS, is a morbid condition of the system, in which one of the most prominent symptoms is the persistent occurrence of crystals of oxalate of lime in the urine. These crystals most commonly occur as very minute transparent octohedra, but sometimes in the form of dumb-bells; in order to detect them, the urine, which usually in these cases presents a mucous cloud, should be allowed to stand for some hours in a conical glass, and after the crystals have gradually subsided, the greater part of the fluid should be poured away, and the drops remaining at the bottom examined with a power of not less than 200 diameters. These crystals, which are insoluble in acetic acid, may occur either in acid or in alkaline urine. Persons who secrete this form of urine are usually dyspeptic, hypochondriacal, and liable to attacks of boils, cutaneous eruptions, and neuralgia. The oxalic acid, in these cases, is not introduced into the system with the food, but is a product of the disintegration of the tissues, and is due to the imperfect oxidation of compounds, which should normally have been converted into carbonic acid. (Anhydrous oxalic acid, C_2O_3 , obviously requires 2 equivalents of oxygen to be converted into carbonic acid, C_2O_2 , or $4CO_2$. Hence, if these two equivalents of oxygen are wanting in the system, in consequence of imperfect oxygenation of the blood, oxalic acid, in combination with lime, appears as a final excretion in place of carbonic acid.) The occurrence of oxalic acid as a persistent sediment in the urine, is not only an indication of an existing morbid condition of the system, but may give rise to two perfectly distinct dangerous complications; (1) a concretion of oxalate of lime (mulberry calculus) may be formed either in the kidney or the bladder; and (2) bad consequences may arise from the poisonous action of the oxalic acid on the digestive organs, on the heart, and on the nervous system.

The treatment is simple. Care must be taken that the patient should avoid articles of diet containing oxalic acid (such as sorrel, rhubarb, tomatoes, &c.), or readily converted into it (such as sugar), and all drinks containing much carbonic acid; while he should take plenty of exercise in the open air, without fatiguing himself; should use the shower-bath, unless he feels chilled and depressed after its application, in which case he should rub the body all over daily with a horse-hair glove; and should employ as a tonic medicine either a little nitro-muriatic acid in a bitter infusion (20 minims of the acid in an ounce and a half of Infusion of Chyretta), or five grains of citrate of iron and quinine three times daily. Under this treatment, the oxalates usually almost entirely disappear from the urine in two or three weeks.

OXENSTIERNA, AXEL, COUNT, an illustrious Swedish statesman, was born at Fånö, in Uppland, 16th June 1583. He was originally educated for the church, and studied theology as well as jurisprudence at Rostock, Jena, and Wittenberg, in the last of which universities he took his degree. Although he afterwards devoted himself to public affairs, he continued all his life to take a deep personal interest in religious questions, and laboured zealously for the extension of the Protestant doctrines. After leaving the university, he visited most of the German courts, but returned to Sweden in 1603, and soon afterwards entered the service

of Charles IX., who, in 1606, despatched him as ambassador to the court of Mecklenburg. He became a senator in 1608—a dignity which had been enjoyed by thirteen of his predecessors in uninterrupted succession. Having displayed great prudence and wisdom in the settlement of certain disputes between the Livonian nobles and the town of Revel, he was appointed by Charles—now infirm from age—guardian of the royal family, and head of the regency. On the accession of Gustavus Adolphus (q. v.), in 1611, O. was made chancellor; and in 1613, acted as minister-plenipotentiary in the negotiations for peace between Sweden and Denmark. In the following year he accompanied his sovereign to Poland, and by the peace of Stolbova, in 1617, terminated hostilities between Sweden and Russia. His political sagacity was not less conspicuously shewn in his successful efforts to prevent Gustavus from marrying Ebba Brahe, a Swedish beauty, and in bringing about a match between his master and the Princess Maria-Eleonora of Brandenburg. In 1621, on the departure of the king for the Polish war, he was charged with the administration of affairs at home, which he conducted with his invariable felicity; subsequently, he was appointed governor-general of the conquered districts; and in 1629, concluded peace with the Poles on highly favourable conditions. For a while O. strongly opposed the desire of Gustavus to take part in the 'Thirty Years' War'; his hope being to see the latter arbiter of the north of Europe; but when he found that the Protestant sympathies of the king were irrepressible, he set about collecting money and troops for the perilous enterprise, with all the quiet but wonderful activity and persistency that so remarkably characterised him. After Gustavus had fairly entered on the bloody struggle, O. joined him, and conducted most of the extensive and complicated diplomacy which the course of events entailed on Sweden. The death of Gustavus for a moment paralysed him, but he instantly recovered, and heroically resolved to continue the contest with the imperialists, in spite of the visible disaffection of many of the German Protestant princes, among others, of the Elector of Saxony. The will of the dead monarch was sent to Stockholm; according to its conditions, the government—during the minority of Christina (q. v.)—was intrusted to five nobles, who empowered the chancellor to prosecute the war. His difficulties were enormous, yet by indefatigable efforts he managed partly to allay the discontents, jealousies, and rivalries of the Protestant leaders. The disastrous defeat of the Swedes at Nordlingen in 1634, and the perplexities which followed it, would have stupified most men in the position of O., but it only called out more energetically his splendid diplomatic genius. Transferring the leadership of the Protestant forces to Duke Bernhard (q. v.) of Weimar, he proceeded, in 1635, to France and Holland, and formed alliances with these countries. Returning to Germany, he assisted in quelling a mutiny among the Swedish troops at Magdeburg; put Pomerania in a state of defence, to resist the meditated attack of the Elector of Brandenburg; renewed the treaty with Poland; and leaving Baner in command of the Swedes, returned to Stockholm in 1636, where he was received with the liveliest enthusiasm. He still continued, however, to direct ably the policy of the Protestants in Germany, till the peace of Westphalia, in 1648, put an end to the war. O.'s son was one of the Swedish envoys who signed the treaty, and it is in a letter to him that the famous sentence of the statesman occurs, *Nescis, mi fili, quantilla prudentia homines regantur*—('You do not yet know, my son, with how little wisdom men are governed'). Christina, who

had been declared of age in 1644, did not shew a proper respect for the advice of O.; and after she had—through mere feminine wilfulness—abdicated in spite of all his protestations, he withdrew from public life, and died 28th August 1654, shortly after she had left Sweden. He entertained a genuine affection for the daughter of his noble master, and in his last moments her name was upon his lips. Some treatises and historical fragments are attributed to him, and his 'Journal' has been published in the 'Stockholm Magazine.' See Lundblad's *Svenskt Plutarch* (2 vols. Stock. 1824); Fryzell's *History of Gustavus Adolphus*; and Geijer's *History of Sweden*.

OX-EYE. See CHRYSANTHEMUM.

OXFORD, an ancient and famous city and seat of learning in England, the chief town of the county of Oxford, is situated on the north-east bank of the Thames (here locally called the Isis), a little above the point where it is met by the Cherwell. Both streams are crossed by numerous bridges, of which the finest are Folly Bridge over the Isis, and Magdalen Bridge over the Cherwell. Lat. of the city, 51° 45' 55" N., long. 1° 15' 29" W. Distance from London, 55 miles W.N.W. Pop. (1871) 34,482; (1881) 40,837. O. occupies an undulating site, is surrounded by rich and wooded meadows, and presents to the eye of the approaching visitor a scene of unequalled architectural magnificence—spires, and towers and domes rising as thickly as chimney-stalks in the manufacturing towns of Lancashire or Yorkshire. The four main streets of O. meet at right angles near the centre of the town, at a place still called Carfax, a corruption of *Quatre voies*, and which appears in Agas's map (*temp. Elizabeth*) as *Cater voys*. These are—Cornmarket Street, leading into St Giles's, and running due north; Queen Street, leading to the railway-stations, and running west; St Aldate's Street, leading to the Isis, and running due south; and High Street, which is the chief street of the city, gracefully curving in an easterly direction, and conducting to the river Cherwell, a smaller river joining the Isis soon after it has passed Oxford.

The western half of the town is the most uninteresting; and it is a misfortune that the railway-stations are placed here, as travellers, on arriving, are introduced to the meanest parts of the city first. The county courts and jail, and the remains of the castle, from which the Empress Maud escaped while it was besieged by King Stephen, will be observed in passing. There is one good street in this part—viz., Beaumont Street, built on the site of the ancient Beaumont Palace, in which Richard I. was born. At the end of this street is Worcester College. Passing to the north from Carfax, along the Cornmarket, the old tower of St Michael's Church is seen, against which stood formerly the north gate of the city; next St Mary Magdalen Church; then the Martyr's Memorial, with the Taylor Buildings and Randolph Hotel on the left, and part of Balliol College and St John's College on the right. St Giles's Church is at the north end of this street, which is very wide, and has a row of elm-trees on each side, forming a picturesque avenue like a foreign *boulevard*. Beyond this, to the north, are the Radcliffe Observatory and Infirmary. The High Street is about 1000 yards in length; it is reckoned one of the noblest streets—architecturally considered—in Europe, and contains, among other edifices, Magdalen College, the new Examination Schools, Queen's College, All-Souls' College, University College, and St Mary's and All-Saints' Churches. Parallel to it is Broad Street, in which are situated Balliol, Trinity, and Exeter

Colleges, the Ashmolean Museum, the Clarendon Buildings, the Sheldonian Theatre; and close by are the Bodleian Library, the Radcliffe Library, and Brasenose College. In St Aldate's Street, which forms the southern part of the series of streets already mentioned as forming one line, and running north and south, is Christ Church College (the entrance tower of which contains the great bell 'Tom of Oxford,' weighing upwards of 17,000 lbs.) and St Aldate's Church. The other colleges and important buildings connected with the University of O. lie back from the principal streets. To attempt particularising the architectural characteristics of each of these edifices is impossible within our limits. It may suffice to say, that though there is nothing extraordinarily fine about the architecture of the colleges, regarded individually, yet the vast number of the structures and variety of styles present a *tout-ensemble* that is altogether sublime. The effect is wonderfully heightened by the interspersing of gardens, meadows, and venerable trees—old as the buildings that tower above them. Christ Church is celebrated for its magnificent hall, picture gallery, and library, as well as for its extensive grounds; its chapel, the cathedral church of O., is Norman in style, but is inferior, both in size and beauty, to most English cathedrals. Merton College is situated a little to the south of the High Street, and still retains the original chapel and part of the other buildings erected by Walter de Merton in the 13th century. Magdalen College retains its celebrated cloister and tower of the 15th c., and the buildings here are the most complete of any college in Oxford. Oriel College, a comparatively modern structure, is very picturesque, but far from chaste in its design; New College ranks among the noblest buildings in the city—the chapel, the hall, the cloisters, the groined gateways, and even some original doors and windows remain, in their exterior at least, as they came from the hand of their master architect, William of Wykeham, 600 years ago; Queen's College is built in the Grecian style of architecture, with a spacious and handsome chapel and a fine library; so is Trinity College; University College is a not unpleasing mixture of Gothic and Italian; Exeter College has a splendid frontage on the west, and its chapel (built 1857–1858), in the Gothic style, is the finest modern building in the city; it has also an excellent hall, and a beautiful library; Balliol College has a remarkably fine chapel, built only a few years ago. Among the other churches in O., besides the cathedral church and the college chapels, are—St Mary's, which is attended by the members of the university; St Martin's, the church of the corporation of O.; St Peter's-in-the-East, with a Norman crypt; St Michael's, with a Saxon tower; and St Aldate's. The chief buildings connected with the university, besides the Bodleian and the Ashmolean Museum already mentioned, are the Radcliffe Library, a circular structure, adorned with Corinthian columns and surmounted by a dome; the Radcliffe Observatory, crowned by an octagonal tower; the University Printing-Office, the Taylor Institution, the Union Debating Rooms, and the New Museum. The Botanic Gardens are nearly opposite Magdalen College. Other notable buildings are—the Town Hall, the Radcliffe Infirmary, the County Gaol, and one or two dissenting places of worship, including a Wesleyan and an Independent Chapel. Lady Margaret Hall and Somerville Hall, founded in 1879 for lady students taking advantage of the lectures of the Oxford association for promoting the higher education of women, are not as such connected with the university.

O. is a mart for the disposal of the agricultural produce of the neighbouring country, but has little trade of its own, and is dependent for its prosperity chiefly on the university. It is a municipal and parliamentary borough, and governed by a mayor, nine aldermen, and thirty councillors, whose jurisdiction, however, does not embrace the university. The university sends two members to parliament; the city now, by the Distribution of Seats Act (1885), sends only one.

O., by the Saxons called Oxnaford, and in *Domesday Book*, Oxeneford (probably 'a ford for oxen'), is a place of great antiquity. The date of its origin is unknown, but as early as the 8th c. there was a nunnery established here; and in 802, an act of confirmation by Pope Martin II. describes it as an ancient seat of learning. It is said to have been a residence of King Alfred, and also of Canute, who held several parliaments within its walls. The townsmen closed their gates against William the Conqueror, who stormed the town in 1067, and gave it to one of his followers, Robert d'Oyley, who built a castle here to overawe the disaffected Saxons, some ruins of which are still to be seen. The paction that terminated the strife between Stephen and Henry II. was drawn up at Oxford. In the reign of Edward III., the preaching of Wickliffe excited great commotion among the students, and threatened well-nigh the dissolution of the university. In the reign of the 'Bloody Mary,' it witnessed the martyrdoms of Ridley, Latimer, and Cranmer; and during the great civil war of the 17th c., it was for a while the head-quarters of the Royalist forces, and was conspicuous for its adherence to Charles I. Ever since that period the city—or, at any rate, the university—has been in general characterised by an extreme devotion to the 'church' and the 'king.'

OXFORD UNIVERSITY is said to have been founded by King Alfred. Without claiming for it an origin quite so ancient, it is certain that from very early times students resorted to Oxford in order to attend lectures there delivered by learned men, and that they lived in the houses of the townspeople. In some cases they combined together, so as to secure the service of a common teacher, with whom they lived in a large tenement called an inn, hostel, or hall. For a long time, however, the great majority of the students lodged in rooms hired from the citizens; and as late as the year 1512, regulations were made for the governance of such students. As their numbers increased, the halls were multiplied. Anthony Wood states that he could shew the names and places of more than a hundred. A great diminution in the numbers of the students took place about the middle of the 15th century. This, among other causes, led to the gradual disappearance of the halls, which were bought up by the wealthier colleges. Only five of the halls now exist, which differ from the colleges only in that they are unincorporated, and have little or no endowments. Residence in private lodgings had also fallen into disuse; and by the time of Queen Elizabeth, it had become a compulsory rule that all undergraduates should reside in some college or hall, at least for the first twelve terms of residence. Now, however, undergraduates may in most colleges live in lodgings from the beginning of their course.

The colleges were founded at various periods, from the end of the 13th c. to the beginning of the 18th. Fourteen out of the 21 were founded before the Reformation. Their object originally was to support limited societies of students, who were to devote their lives to study—by no means, as at present, to educate large classes of the community.

Students, other than those on the foundation, seem not to have been regarded by the founders as an essential part of the college. The colleges arose, as has been already said, partly instead of the old halls, and were partly at first connected with the monasteries, it being by means of these institutions that benevolent persons were enabled to give permanent support to poor secular scholars. University and Balliol, which now rank as the oldest colleges, were in point of fact halls supported by endowments held in trust for the maintenance of their students. The originator of the collegiate system, in anything like its present form, was Walter de Merton, who, besides having founded Merton College, is entitled to the honour of having mainly contributed to fix the university in its present site. All those on the foundation of the colleges before the Reformation were called Clerici. The great majority of the fellows were required to take priest's orders within a certain period after their election. This requirement of course involved celibacy, which, besides, was expressly imposed in some colleges; and practically, in old times as now, was enforced by the rule of life and the obligation of residence. Within the last few years, in some of the colleges the restriction of celibacy has been, under certain conditions, remitted in the case of fellows engaged in college work.

Under a statute passed in 1868, any person may now become a member of the university, without becoming a member of a college or hall, provided he satisfies certain disciplinary requirements. For such purposes these unattached students are under the control of a board of delegates; but no special provision is made for their instruction. In 1871, the new foundation of Keble College, built in memory of John Keble, was admitted to enjoy the same privileges (save as regards the academical status of its head) as are possessed by the existing colleges and halls.

Previous to the statute 17 and 18 Vict. c. 81, the constitution of the university was as follows: 1. The Hebdomadal Board, or Weekly Meeting, consisting of the Heads of Houses and the two Proctors, which body exercised the chief share of the administration of the university, and possessed the exclusive power of initiating legislation; 2. Congregation, consisting of certain university dignitaries, which met merely for the purpose of conferring degrees; 3. Convocation, consisting of all Masters of Arts, a body whose consent was necessary before any of the measures proposed by the Hebdomadal Board could become law, which elected the chancellor, the two representatives of the university in parliament, several of the professors, and dispensed the ecclesiastical patronage of the university. The statute referred to introduced important changes. The Hebdomadal Board has been changed into the Hebdomadal Council, consisting of the chancellor, the vice-chancellor, the proctors, six heads of houses, six professors, and six members of convocation of not less than five years' standing—such heads, professors, and members of convocation being elected by congregation, and holding office for six years. Congregation, again, now consists of all the great officers of the university, the professors, the public examiners, and all resident masters; and on this body is now bestowed the power of accepting or rejecting, and of amending any statute framed by the Hebdomadal Council. The composition and powers of Convocation remain unchanged. The students not on the foundation are for the most part commoners. In Worcester College and the halls there is still a class of fellow-commoners, who pay larger fees, and enjoy certain privileges. They mainly consist of men above the ordinary age of

undergraduates, who wish to have the intellectual advantages of the university without being subjected to the common routine of discipline. All other formal distinctions due to wealth or poverty are almost entirely abolished; such as the special privileges of peers, and the regard had to the poverty of candidates in the case of certain scholarships. It is very difficult to ascertain the actual number of students at any one time in Oxford, but now it is probably seldom above 1800.

There are four terms in each year—viz., Michaelmas Term, which begins on the 10th of October and ends on the 17th of December; Hilary Term, which begins on the 14th of January and ends the day before Palm Sunday; Easter Term, which begins on the Wednesday in Easter-week, and ends on the Friday before Whitsunday; Trinity Term, which begins on the Saturday before Whitsunday and ends on the Saturday after the first Tuesday in July. Full Term, as it is called, does not begin till the first day of the week after the first congregation is held. By undergraduates, Michaelmas and Hilary Terms are kept by six weeks' residence, and Easter and Trinity Terms by three weeks each; but more than this is required by most of the colleges. Twenty-four weeks may be taken as the ordinary length of the academic year. Twelve terms of residence are required for the degree of B.A. from all. The degree of M.A. is obtainable in the twenty-seventh term after matriculation. By a statute passed in 1850, the following examinations were made necessary for a degree in arts; but their nature has been considerably changed by the new statutes which came into effect 1873—1874: 1. Responsions, called 'Little Go' or 'Smalls' in the familiar language of undergraduates, are obligatory upon all. The university does not, as to this or any other pass examination, fix a limit of time within which they must be passed; but most colleges require their members to pass responsions, at least within their first year of study. Subjects: one Latin and one Greek author—or portions of them, as five books of Homer, five of Virgil, two Greek plays, &c.—with a paper of grammatical questions; a piece of English to be translated into Latin; two books of Euclid, or algebra up to simple equations inclusive; and arithmetic. 2. The First Public Examination, or Moderations, is also obligatory upon all. Candidates must have entered upon their fourth term. Subjects: the Four Gospels in Greek (except in the case of persons not members of the Church of England, when some one Greek author is to be substituted); one Greek and one Latin author, not the same as those offered for responsions, and one must be a poet, the other an orator; a piece of English into Latin, and a paper of grammatical questions; logic, or Euclid III. and IV., 1—9, and algebra. Honours are awarded at this examination both in classics and pure mathematics. Candidates are recommended to take up especially poets and orators. Verses, as well as Greek and Latin prose-writing, and a paper of grammatical and philological questions, are set. In the mathematical school, which in this examination exists as a separate school for honours only, candidates are examined in pure mathematics up to the Integral Calculus and the Calculus of Finite Differences inclusive. 3. The Second Public Examination held twice a year, to be passed not earlier than the 12th term, and for honours not later than the 16th term of standing; unless the candidate has been classed in some other school of the Second Public Examination, in which case he may be admitted up to the 20th term inclusive. This examination consists of three parts: (1.) an examination in the rudiments of faith and religion, or in the case of those who (or whose guardians)

object to such examination, certain substituted books or subjects; (2) an examination of those who do not seek honours; and (3.) an examination for those who do seek honours. In this last there are, in Oxford phraseology, six schools: *Literæ Humaniores*, Mathematics, Natural Science, Jurisprudence, Modern History, Theology. Candidates are entitled to a degree of B.A. who, having passed the two previous examinations, also passed the examination appointed for those who do not seek honours, or who obtain honours in any one of the six honour-schools. But every candidate, except he has obtained honours in the Theology School, must have satisfied in the rudiments of faith and religion or the substitute. By these rudiments are understood the Old and New Testaments (Gospels and Acts of the Apostles in the original Greek); and the 39 articles. The pass examination embraces subjects chosen from at least two out of the three following groups: (a) Greek and Roman history and philosophy; (b) English, modern languages, political economy, and law; (c) geometry, mechanics, chemistry, and physics. Out of these the candidates must select three subjects, one of which must be either (1) ancient philosophy and history (in the original Greek, or Greek and Latin); or (2) a modern language (French or German). The classical books must be other than those offered for Responsions and Moderations. Candidates for honours may select any one, or more than one of the six schools. The most popular and influential of these is the school of *Literæ Humaniores*. The examination in this school includes (1) the Greek and Latin languages; (2) the histories of ancient Greece and Rome; (3) logic, and the outlines of moral and political philosophy. Candidates may also offer certain special subjects in any of these three departments. The republic of Plato and the ethics of Aristotle form the basis for philosophical study, though they are every year more largely supplemented by modern philosophy. Next in the numbers of its candidates is the school of Modern History, which includes (1) the continuous history of England; (2) general history during some period, selected by the candidate, from periods to be named from time to time by the Board of Studies; (3) a special portion of history, or a special historical subject, carefully studied with reference to original authorities. The School of Jurisprudence includes (1) general jurisprudence; (2) the history of English law; (3) some department of Roman, and it may be, of English law; (4) international law, or a specified department of it. The School of Mathematics embraces pure and mixed mathematics (algebra, trigonometry, calculus, mechanics, optics, astronomy). The School of Natural Science has a double examination for honours—a preliminary and a final. The preliminary examination, incumbent upon all, is restricted to the elementary parts of mechanics, physics, and chemistry. In the final examination, the candidate may offer himself for examination in one or more of the three general subjects of physics, chemistry, and biology. The examination in the Honour School of Theology includes the Holy Scriptures, dogmatic and symbolic theology, ecclesiastical history and the fathers, the evidences of religion, liturgies, sacred criticism, and the archaeology of the Old and New Testaments. A knowledge of Hebrew will have weight in the distribution of honours. The organisation of these schools is at present the main function of the university, as distinct from the colleges. Professorial teaching on its own account only exists to a very limited extent. In the main, the teaching power of the colleges is devoted to preparing their undergraduate members for these various examinations.

Examinations also take place for degrees in law,

medicine, divinity, and music; but these are in great measure formal. The examinations for degrees in arts are the proper work of the university.

Besides these honours, various distinctions are conferred by the university. There are several university scholarships, more particularly the Vinerian law fellowships and scholarships; the Eldon law scholarship; one Sanscrit and two Hebrew scholarships yearly; two mathematical scholarships; the Hertford scholarship, for the encouragement of the study of Latin, and the Ireland and Craven scholarships, for the encouragement of the study of classics. There is also the Newdigate prize for the best composition in English verse; and the three chancellor's prizes for the best compositions in Latin verse, Latin prose, and English prose; the Gaisford prizes for Greek composition; and the Arnold, Stanhope, and Marquis of Lothian's prizes for the best essays on an historical subject. But the great prizes are the scholarships and the fellowships. By the commissioners under 17 and 18 Vict. c. 81, these have been for the most part thrown open, and are now awarded after examination without restrictions as to kin or place of birth. At All-Souls, and also at St John's College, since the labours of the commissioners, an attempt has been made to keep up the former exclusiveness. The scholarships, which are so numerous as to be within the reach of any young man of ability, range from £60 to £80 a year, with rooms free, which would go a considerable way towards defraying the expense of a university education. At the close of this education come the fellowships; and it has been calculated that when the arrangements of the commissioners are complete, there will be between 20 and 30 fellowships, mostly about £300 per annum, open yearly to competition.

Oxford is, of course, chiefly fed from the great English schools. A close connection subsists, by the terms of the foundation, between Winchester and New College, between Westminster and Christ Church, and between Merchant Taylors' and St John's. For the nature of this connection, see under these colleges. A student desirous of going to Oxford, must apply to the Head of the College to which he wishes to belong. Application in former times had to be made early, as all the good colleges were filled up for several years in advance. But now that undergraduates are allowed by most colleges to live in lodgings from the first, a candidate can have no difficulty in securing admission even to a distinguished college at short notice. There is no university examination at matriculation; but all the good colleges have such an examination before they receive any one—the standard of the examination, of course, varying with the college. After being received into the college, the undergraduate is sometimes assigned to a college tutor, who exercises a special control over his reading; but he also attends the instruction of the other college tutors or lecturers, as the course of his studies may require. The cost of tuition varies at different colleges, but an average of £65 may be given as paid by the undergraduate during his whole career. This payment is at some colleges distributed over three, at others over four years. Besides this, almost every undergraduate finds it necessary, at some period before taking his degree, to read with a private tutor, whom he chooses for himself. Private tuition has grown to be quite an institution in Oxford, though not formally recognised. Many of the ablest young men, after taking their degree, remain in Oxford for a year or two, taking private pupils. In this way an undergraduate, even of a badly-taught college, could secure the advantages of the best tuition. But

during the last few years, the lecturers in different colleges have more and more combined and systematised their work; and thus to a slight extent obviated the need for private tuition. Much discussion has taken place on the merits and faults of this system; but, on the whole, it must be allowed to be useful for the tutor, as clearing up and concentrating his knowledge, while, at least to undergraduates who read for honours (with a few rare exceptions), it may be considered as absolutely necessary. Private tutors usually charge £10 a term for three hours a week. Previous to 1852, the professoriate of Oxford was strictly ornamental. A great effort was then made to stir it into life, which has been partially successful. New professorships were created, and the endowments of old ones were increased by the commissioners, under 17 and 18 Vict. c. 81. But the former of these measures, at least, whatever it may have done for the interests of science, has produced but little effect on the undergraduates. They still limit their range of studies by the requirements of the examinations of the schools, and it were hard to expect them to do otherwise. But professorial teaching has undoubtedly become more popular in the ordinary branches of study. Lectures by the professors of Law and Modern History, of Moral Philosophy, Logic, Greek, and Latin, are felt to be useful, and are therefore well attended. Considerable changes in the university system were contemplated in 1881, in accordance with the reforms suggested by the university commissioners. Amongst other changes, it was proposed that professors should do more of the teaching, and that fellowships should be more numerous, of less value, and of shorter tenure than at present. The expenses vary at different colleges, not only indirectly from the tone of the society, but even directly from the charges made for necessities. A man should be exceedingly comfortable at Oxford with £200 a year; on £150, he can manage with economy. There have been instances of men passing creditably through the university course on £100 a year; the necessary expenses do not exceed that sum. It appears that some unattached students cover their board, lodging, and tuition for about £45 a year. Discipline inside the college is maintained by the head of the house and the tutors; in the town and its neighbourhood, by the proctors, who are university officers invested with great authority. As a rule, this authority is well exercised. According to the *Universities Commission Report* (1874), the revenue of the colleges and university in 1871 was £413,000.

The following is a list of the colleges and halls as they rank in the university; an account of each will be found in its alphabetical place: University, Balliol, Merton, Exeter, Oriel, Queen's, New College, Lincoln, All Souls, Magdalen, Brasenose, Corpus Christi, Christ Church, Trinity, St John's, Jesus, Wadham, Pembroke, Worcester, Hertford, Keble, St Mary Hall, New Inn Hall, and St Edmund Hall. To these may be added Charsley's Hall and Turrell's Hall, both being private halls, in virtue of a statute passed in 1854, empowering any M.A. of a certain standing to open a private hall on his obtaining a licence from the vice-chancellor. The Unattached Students now number upwards of 350; but the present system of university teaching is not very favourable to either their increase or progress.

Among the books which may be consulted are—Ayliffe's *History of Oxford*, Wood's *Athenæ Oxonienses*, the *University Calendar*, Parker's *Handbook to Oxford* (1875), the *Student's Handbook to the University of Oxford*, and H. C. Maxwell Lyte's *History of Oxford University* (1885).

OXFORD BLUES. See HORSE GUARDS, ROYAL.

OXFORD CLAY, the principal member of the Middle Oolite series, is a bed of stiff dark-blue or blackish clay, sometimes reaching a thickness of 600 feet. There occur in its lower portion in some places layers of tough calcareous sandstone, called Kelloway Rock, from a place in Wiltshire, where it is quarried. The O. C. lies beneath the plain on which Oxford is built, and extends south-west and north-east from the shore at Weymouth to the fen lands south of the Wash, thence it may be traced through Lincoln into Yorkshire, until it disappears under the sea at Scarborough. The close packing of the fossils in the fine compact clay has caused them to be beautifully preserved; the shells frequently retain their iridescence, and even the softer parts of the cephalopods have sometimes left with tolerably clear definition their form in the clay. The fossils are, however, often filled with iron pyrites, which, on exposure to the atmosphere, readily decomposes and destroys all traces of the beautiful organism. The remains of chambered shells of the genera belemnites and ammonites are very abundant, and with them are associated other shells, interesting crustacea, and the species of fishes and reptiles which are characteristic of the oolite.

OXFORDSHIRE, an inland county of England, bounded on the S. by the River Thames, E. by Bucks, W. by Gloucester. Area, 472,717 acres. Pop. (1871) 177,975; (1881) 179,559. The surface, where it is not level, is undulating. In the north-west the hills rise in Broom Hill to 836 feet above sea-level, and in the south-east of the county are the Chiltern Hills (q. v.), rising near Nutfield to 820 feet in height. It is watered along its southern border by the Thames, and the other chief rivers are the Windrush, Evenlode, Cherwell, and Thame, affluents of the Thames. By means of the Oxford Canal, which joins the Thames at Oxford, the towns and districts lower down the river (Abingdon, Wallingford, &c.), are supplied with coal from the Leicestershire coal-fields. The soil is fertile; the state of agriculture is advanced, 417,606 acres being under crops, fallow, or grass, in 1881; and the county may be considered one of the most productive in the country. Three members are returned to the House of Commons for the county.

OXIDATION is the term applied to the union of any body with oxygen, the body being then said to be *oxidised*, and the resulting compound being termed an *oxide*. Many bodies possess the property of entering into several distinct combinations with oxygen. For example, manganese (Mn) forms no less than six such compounds—viz., MnO , Mn_2O_3 , Mn_3O_4 , MnO_2 , MnO_3 , Mn_2O_7 , which represent different stages of oxidation.

OXIDES, METALLIC, are the most important of all the compounds of the metals, and in many cases occur naturally as abundant and valuable ores. They are divided by chemists into three classes—viz., (1) basic oxides or bases, (2) saline or indifferent oxides, and (3) acid oxides or metallic acids. The different oxides of the same metal usually afford illustrations of two, and not unfrequently of all three of these classes. Thus (to take the case of manganese referred to in the last article) the protoxide (MnO) is a powerful base, the red oxide (Mn_2O_3) is a saline or indifferent oxide, shewing little tendency to combine either with acids or alkalies, while permanganic acid (Mn_2O_7) presents all the properties of an acid. As a general rule, the greater the number of atoms of oxygen which an oxide contains, the less is it disposed to unite with the acids; on the contrary, it frequently possesses acid properties, and then unites with bases

to form salts. Protoxides generally are strong salifiable bases; they require one equivalent of a monobasic acid to form neutral salts. Sesquioxides are weaker bases; their salts are usually unstable; they require three atoms or equivalents of a monobasic acid to form a salt which is neutral in composition, though it may not be neutral to test-paper; and in general, all oxides require as many equivalents of acid as they contain atoms of oxygen in their composition. Some of the metallic acids, like the stannic and titanio, contain two atoms of oxygen to one atom of metal, but most of them contain three atoms of oxygen—such, for example, as the manganic, ferric, chromic, tungstic, molybdic, and vanadic acids; whilst in a few cases, such as the arsenic, antimonio, and permanganic, the proportion of oxygen is still higher.—Miller's *Inorganic Chemistry*, 2d edit. p. 314. Of the basic oxides, which form by far the most important class, it may be observed that they are devoid of all metallic appearance, and present the characters of earthy matters, and that six only of them are soluble in water to any considerable extent—viz, the three alkalies, and baryta, strontia, and lime. All the oxides are solid at ordinary temperatures, and as a general rule, the addition of oxygen to a metal renders it much less fusible and soluble; the protoxide of iron, the sesquioxide of chromium, and molybdic acid being the only oxides that melt more readily than the metal.

OXLEYA, a genus of trees of the natural order *Cedrelaceæ*, of which one species, *O. xanthoxyla*, the **YELLOW WOOD** of Eastern Australia, is a very large tree, 100 feet high, valuable for its timber.

OXUS, the ancient name of a great river in Central Asia, which is called by the Turks and Persians **JIRÓN**, and **AMÚ** or **AMÚ-DARIA** by the natives of the country through which it flows. The **O.** rises in Lake Sari-kol, in the elevated plateau which separates Eastern and Western Turkestan. It flows through Buddakshan, Bokhara, and Khiva, and empties itself by several mouths into the Sea of Aral. In the first part of its course, its volume is increased by numerous affluents, but it receives no tributaries after entering Khiva, from which point its course is wholly through a dry sandy desert. Its total length is about 1150 miles. The value of the Oxus for the purpose of water communication, is said by recent Russian geographers to have been much overrated in Europe; and they add that, in summer, vessels of even slight draught could only be got upon the stream by shutting off the irrigation canals, and risking the desolation of the country dependent on them for its crops. The true value of the Oxus lies in the means it will supply of irrigating the sterile alluvial wastes through which it runs. Before the Christian era, it is believed that the Oxus flowed into the Caspian, and that since 600 A.D. it has twice changed its course (see **ARAL**). A great part of the old bed of the Oxus has recently been explored by M. Stebnitzki (*Bulletin de la Soc. de Géogr. de Paris*, April 1871), who has ascertained that it has a fall towards the Caspian, from which he infers that its course was not changed by an upheaval of the Turcoman desert, but by the simple accidents of fluvial action on an alluvial soil. In his address to the London Geographical Society in May 1872, Sir Henry Rawlinson said the restoration of the Oxus to its old bed was then under the serious consideration of the Russian government, that it was a work of no engineering difficulty whatever, and would assuredly be accomplished as soon as the neutrality of Khiva was secured.—See *A Journey to the Source of the Oxus*, by John Wood, with Essay of the Geography of the Oxus Valley by Colonel Yale,

1873; also *The Road to Meru*, by Sir H. Rawlinson, in the Proceedings of the Geog. Society, 1879.

OXYA'CIDS. When Lavoisier, in 1789, gave the name of oxygen to the *Dephlogisticated Air* discovered, in 1774, by Priestley, he believed that the presence of that body was essential to the existence of an acid, and this view was supported by the composition of the principal acids which were then known, such as sulphuric, nitric, carbonic, and phosphoric acids. But, by degrees, acids were discovered into which no oxygen entered, but which always contained hydrogen, and hence acids were divided into two great classes, the *oxyacids* and the *hydracids*; oxygen being supposed to be the acidifying principle in the former, and hydrogen in the latter. At the present day, scientific chemists usually restrict the term *acid* to compounds into which hydrogen enters, and the acids are regarded as salts of the last-named element; thus, sulphuric acid (H_2SO_4) and nitric acid (HNO_3) are the sulphate and nitrate of oxide of hydrogen; hydrochloric acid (HCl) is chloride of hydrogen, &c.

OXYCHLORIDES, chemical compounds containing both chlorine and oxygen in combination with some other element or radical. Chloride of lime (CaOCl), chloride of potash (KOC), oxychloride of lead or Turner's yellow belong to this class.

OXYGEN (symb. O , equiv. 8; new system, 16—see **CHEMISTRY** in *SUPP.*, Vol. X.—sp. gr. 1.1056) is a colourless, inodorous, tasteless gas, long regarded as a 'permanent' gas, but liquefied by Pictet of Geneva for the first time in 1877. Its chemical affinities for other elementary substances are very powerful; with most of them it is found in combination, or may be made to combine, in more than one proportion; with several in 4, 5, or 6 proportions; and there is only one element (fluorine) with which it does not enter into any combination. Owing to the intensity with which many of these combinations take place, this gas has the power of supporting Combustion (q. v.) in an eminent degree. Of all known substances, it exerts the smallest refracting power on the rays of light. It possesses weak but decided magnetic properties, like those of iron, and like this substance, its susceptibility to magnetisation is diminished or even suspended by a certain elevation of temperature. It is only slightly soluble in water; 100 cubic inches of that liquid dissolving 4.11 cubic inches of gas at 32°, and only 2.99 inches at 59°.

Oxygen gas is not only respirable, but is essential to the support of animal life; and hence it was termed *vital air* by some of the older chemists. A small animal placed in a bell-glass containing pure oxygen will not be suffocated so soon as if it were placed in the same glass filled with atmospheric air. For further details on this property of oxygen, the reader is referred to the article **RESPIRATION**.

Oxygen is the most abundant and the most widely distributed of all the elements. In its free state (*mixed* but not *combined* with nitrogen), it constitutes about a fifth of the bulk, and considerably more than a fifth of the weight of the atmosphere. In combination with hydrogen, it forms eight-ninths of all the water on the globe; and in combination with silicon, calcium, aluminium, &c., it enters largely into all the solid constituents of the earth's crust; silica in its various forms of sand, common quartz, flint, &c.—chalk, limestone, and marble—and all the varieties of clay, containing about half their weight of oxygen. It is, moreover, found in the tissues and fluids of all forms of animal and vegetable life, none of which can support existence independently of this element.

There are various modes of obtaining oxygen, the

simplest of which consists in the exposure of certain metallic oxides to a high temperature. It was originally obtained by its discoverer, Dr Priestley, from the red oxide of mercury, which, when heated to about 750°, resolves itself into metallic mercury and oxygen gas. It may be similarly obtained from red oxide and peroxide of lead, the resulting products in these cases being protoxide of lead and oxygen. The following are the chief methods now employed: (1.) The black oxide (or binoxide) of manganese (MnO_2) is much employed as a source of this gas. The mineral is reduced to small pieces of about the size of a pea, and introduced into an iron bottle, with a pipe through which the gas may escape. When the bottle is placed in a furnace, and attains a red heat, the mineral parts with one-third of its oxygen, and the red oxide of manganese (MnO, Mn_2O_3) remains behind; the reaction being explained by the equation:

(2.) A very pure and abundant supply of oxygen may be obtained by heating chlorate of potash (KO, ClO_3), which yields up all its oxygen (amounting to 39·16 per cent), and leaves a residue of chloride of potassium. One ounce of this salt yields nearly two gallons of oxygen gas. It is found by experiment, that if the chlorate of potash is mixed with about a fourth of its weight of black oxide of copper, or of binoxide of manganese, the evolution of the gas is greatly facilitated, although the oxides do not seem to undergo any change during the process. (3.) Oxygen is readily obtained by heating strong sulphuric acid with about half its weight of powdered black oxide of manganese, or chlorate of potash, in a glass retort; the reaction in the former case being expressed by the equation:

and in the latter case, being of a more complicated character. (4.) Various processes have been proposed for obtaining the gas on a large scale, of which the following, recommended by St Claire Deville and Debray, is perhaps the best: The vapour of hydrated sulphuric acid is passed over red-hot platinum, by which it is decomposed into oxygen and sulphurous acid, the latter of which may easily be separated (and made available for the formation of sulphites) by its solubility in water or alkaline solutions. It has been calculated that a cubic metre (35·375 cubic feet) of oxygen costs 8s. 4d. when obtained from chlorate of potash; nearly 4s. 1d. when obtained from manganese; and only 10d. when obtained from sulphuric acid.

Of the compounds of oxygen, it is unnecessary to speak here, as they are described in the articles on the other chemical elements.

Oxygen was discovered almost simultaneously, in the year 1774, by Priestley and by Scheele, the English chemist having the precedence by a few weeks. Priestley gave it the name of *Dephlogisticated Air*; Scheele termed it *Empyreal Air*; Condorcet shortly afterwards suggested *Vital Air*, as its most appropriate designation; and in 1789, Lavoisier, who, by a series of carefully conducted and very ingenious experiments, proved that the combustion of bodies in the air consisted essentially in their chemical combination with oxygen, and thus overthrew the *Phlogiston* (q. v.) theory, gave it the name which it now retains, in consequence of his (erroneously)

believing that it possessed a certain property which is described in the article OXYACIDS.

OXYHYDROGEN MICROSCOPE. See SOLAR MICROSCOPE.

OXYRHYNCHUS, the name of a celebrated Egyptian fish, said to be revered throughout Egypt, and sacred to the goddess Athor. Its name in Egyptian is *kha*, and the fish in the hieroglyphs was used for this syllable, and particularly expressed the idea of the body. In the ritual, the deceased particularly stated that he had not caught this fish. The name appears to have comprised the genus *Mormorus*, distinguished by its pointed nose and long dorsal fin. The fish was worshipped in one of the nomes, which was called after it, and the inhabitants held it in such reverence that they would not touch any fish captured by a hook. When the portions of the body of Osiris were flung into the Nile, this fish alone ate one portion of his body. The O. was not eaten in Egypt, except by the natives of the Cynopolites Nomos. Its modern name is *Mizeleh*, which seems retained in the Coptic Pemege, the name of the city of Oxryhynchus. It is represented both in the sculptures and on the coins of the Nome, and was anciently embalmed.—The city of Oxryhynchus is the modern Behneseh, lying on the west bank of the Nile, in Lower Egypt, near the Bahr-el-Jusuf.

OXYURIS VERMICULARIS is the name now assigned by most zoologists to the intestinal worm described as *Ascaris* (q. v.) *vermicularis*, yet it is the original and true *Ascaris*. For the mode of recognising the presence of this worm, and treating patients suffering from its presence, the reader is referred to the articles VERMIFUGES and WORMS.

O'YER AND T'ERMINER (Fr. *ouir*, to hear; *terminer*, to determine). A commission of oyer and terminer is granted by the crown to the judges and others to hear and determine all treasons, felonies, and trespasses; and it is by virtue of this commission that the judges on circuit dispose of criminal cases in the various circuits. Sometimes a special commission of the same kind is issued, authorising the judges to go and try prisoners at other than the ordinary times.

O'YSTER (*Ostrea*), a genus of lamellibranchiate molluscs, of the section with a single adductor muscle. See LAMELLIBRANCHIATA. The shell consists of two unequal and somewhat irregularly shaped valves, of laminated and coarsely foliated structure; and the hinge is without tooth or ridge, the valves being held together by a ligament lodged in a little cavity in each. The animal is, in its organisation, among the lowest and simplest of lamellibranchiate molluscs. It has no foot; and, except when very young, no power of locomotion, or organ of any kind adapted to that purpose. Its food consists of animalcules, and also of minute vegetable particles, brought to it by the water, a continual current of which is directed towards the mouth by the action of the gills. The gills are seen in four rows when the valves of the shell are separated, a little within the fringed edge of the mantle. In the most central part is the adductor muscle; towards the hinge is the liver, which is large; and between the adductor muscle and the liver is the heart, which may be recognised by the brown colour of its auricle. The mouth—for, as in the other lamellibranchiata, there is no head—is situated beneath a kind of hood, formed by the union of the two edges of the mantle near the hinge. It is jawless and toothless. The ovaries are very large during the season of reproduction, which extends over certain months in summer, when oysters are out of season for the

table. Oysters are hermaphrodite. They produce vast numbers of young. Leeuwenhoek calculated that from 3000 to 4000 exist within an O. at once when 'sick,' 'milky' or full of spawn; and according to Poli, one O. produces about 1,200,000 eggs. The eggs are hatched within the shell and mantle of the parent, and the young are to be seen swimming slowly in a whitish and mucous or creamy fluid surrounding the gills, which becomes darker and of a muddy appearance when they are about to be expelled. Each young O. is then about $\frac{1}{16}$ th of an inch in length, and about two millions are capable of being closely packed in the space of a cubic inch. When the parent O. expels the young, and this is done simultaneously by multitudes on an oyster-bank, the water becomes filled as with a thick cloud, and the spawn—called *spat* by fishermen—is wafted away by currents; the greater part, of course, to be generally lost, by being driven to unsuitable situations, as exposed rocks, muddy ground, or sand to which it cannot adhere, or to be devoured by fishes and other marine animals, but some to find an object to which it can attach itself for life. The young come forth furnished with a temporary organ for swimming, ciliated, and provided with powerful muscles for extending it beyond the valves and withdrawing it at pleasure; and when the O. has become fixed in its permanent place of abode, this organ, being no longer of any use, has been supposed to drop off, or gradually to dwindle away and disappear. Frank Buckland some years ago expressed the opinion, that the swimming organ of the young oyster is the 'lungs,' and remains as the 'lungs'

Fig. 1.

Fig. 2.

in the mature oyster. The four figures here given represent the young oyster much magnified. Figs. 1, 3, 4 are views of the upper and under side; fig. 2 is an edge view. In very favourable situations, oysters grow rapidly, so that the Com-

Fig. 3.

Fig. 4.

mon O. is ready for the table in a year and a half or two years; but in other places, a longer time is required, often about five years.

The species of O. are numerous, and are found in the seas of all warm and temperate climates. None have been found in the coldest parts of the world. The Common O. (*O. edulis*) is the only British species. Like it, the other species are generally found where the water is of no great depth; and some of them, also like it, are very abundant in estuaries, where the water is not very salt. The mangrove swamps of warm climates often abound in oysters of excellent flavour (*O. parasitica*, &c.) adhering to the roots and branches of the trees, within the reach of the tide. Some of the species differ from the Common O. not a little in form, as the LONG-HINGED O. (*O. Canadensis*) of North America, which is very elongated; and some of them far exceed it in size. Sir J. E. Tennent states that he measured the shell of an edible O. in Ceylon, and found it a little more than 11 inches in length by half as many in breadth; 'thus unexpectedly attesting the correctness of one of the stories related by the historians of Alexander's expedition, that in India they had found oysters a foot long.' Some species of O. have the valves plaited with strong longitudinal plaits.—For the illustrations here given, we are indebted to the kindness of the editor of the *Field*.

Young oysters readily attach themselves to the shells of old ones, and thus, in favourable circumstances, oyster-banks increase rapidly, so as to fill up shallow parts of the sea, and to form walls which effectually resist the waves and tide. This is very remarkably the case on the alluvial shores of Georgia and some other parts of North America, where these banks are called *Racoon Banks*, because the racoon, among other animals, visits them to feed upon the oysters. Marshy land extends inwards from 12 to 18 miles from the sea, with tidal rivers meandering through it, and these rivers are kept pretty constant to their channels by the walls of living oysters on both sides. Large bunches of oysters may even be found among the long grass. It is not unusual for the inhabitants of the neighbourhood to light a fire, and roast a bunch of oysters on the spot. So abundant are the oysters in many places, that a vessel of 100 tons might be loaded within three times her own length. American oysters, which are of excellent flavour, have of late been imported (alive) into Britain to the value of £100,000 a year.

Notwithstanding the prodigious fecundity of the O., however, the beds or banks which yield it for the markets of Britain and other European countries are not sufficiently productive to satisfy the demand, and it is not so much an article of ordinary food for all classes, as a luxury of the wealthy. The usual mode of taking oysters by dredging is destructive, although, for oyster-beds, which are at all states of the tide covered with a considerable depth of water, nothing better has been devised, and the anxiety of fishermen to make the most of the present opportunity has caused many beds to be almost ruined by over-dredging. But the artificial formation of oyster-beds has been resorted to with great promise of success. It is indeed no novelty, having been practised by the Romans. Pliny says that 'the first person who formed artificial oyster-beds was Sergius Orata, who established them at Baia. . . . This was done by him, not for the gratification of gluttony, but for the sake of gain, as he contrived to make a large income by the exercise of his ingenuity.' Sergius Orata lived in the time of Augustus. Among the *vivaria* of later emperors and other wealthy Romans were *ostreararia*, specially

devoted to oysters; and oyster-culture has never ceased to be practised in Italy, although to an inconsiderable extent, and particularly in Lake Fusaro, the Acheron of Virgil, a muddy salt-water pond, nowhere more than two yards deep. In Britain, it has also long been practised to some extent, particularly on the coasts of Kent and Essex, for the supply of the London market.

In 1864, an act of parliament was passed, giving exclusive rights to a Company, called the 'Herne Bay, Hampton, and Reculver Oyster Fishing Company,' over a certain portion of the shore at Herne Bay, extending about six miles in length by 1½ in breadth. The oyster-beds fished by the public had, till then, yielded a very small supply; and it was urged that this supply could be largely increased by a well-managed Company. In order that the public should not be injured by this legislation, it was declared by one of the clauses of the Act that 'If the Company fail to maintain and cultivate the beds, or to produce well-fed oysters fit for the public market in such quantities as to be of public advantage, all the privileges conferred on the Company would be withdrawn, and the dredging of the beds, as formerly, thrown open to the public to fish.'

In 1869, the Board of Trade commissioned Mr Pinwell, Inspector of Oyster Fisheries, to visit the oyster-culture grounds of France, in order to ascertain whether we could gather any useful hints therefrom. In his Report he explained that the English plan, as conducted at Herne Bay, Reculver, Whitstable, Langston Harbour, the Isle of Wight, and other localities, depends on the provision of salt-water tanks or ponds, in which the oysters are kept for a certain time. In France, the system is much more elaborate. He found that the coast is parted off into divisions or districts, each of which is placed under a maritime prefect. Each district is divided and subdivided into smaller portions, managed by commissioners, inspectors, syndics, and watchmen. The determination of 'close-time,' when oyster-fishing is totally prohibited; the decision how much to fish up, and how much to reserve for re-stocking; the discrimination between public oyster-beds and those which are made over to individuals by 'concessions;' the control of the foreshore; the maintenance of oyster-breeding farms; the prevention of poaching by fishers not belonging to the respective districts—occupy quite an army of officials. Mr Pinwell recommended the adoption of some matters of detail from the French system, but not an imitation of the elaborate official machinery.

In 1872, the enhanced price of oysters in France attracted much public attention. Close observers arrived at an opinion that it was due to three causes—the impoverishment of some of the beds by injudicious dredging; a greatly increased demand for the supply of Germany and Russia; and a private understanding between many of the French Companies, leading to something very like a monopoly. The price per 100 was 1·20 francs in 1840, 2·83 francs in 1856, 4·58 francs in 1860, 7·20 francs in 1868, and no less than 11·20 francs in 1872. For consumption and further development, about 380,000,000 oysters were taken in 1881 from the basin of Arcachon, where the government has preserved banks, and the beds of Marennes and Concarneau; while, in 1880, from twenty-one places where this industry is carried on, about 195,000,000 were sent to market.

In 1874 the free fishers and the public of Herne Bay complained that the oyster company in that locality had not fulfilled the required conditions, while the company declared they had kept their agreement. The Board of Trade arranged a compromise, by which a certain portion of the ground

was re-transferred to the public or free fishers; the remainder being left in the possession of the company, who would hold the exclusive right of fishing thereon, so long as they maintained the beds.—It is gratifying to find that oyster-culture is receiving much attention in Australia. Oyster-farms were established both in New South Wales and in Victoria in 1872.

Oysters live equally well in situations where they are constantly under water, and in those which are left dry by the retiring tide. In 1882, a discovery was made of 10,000 acres of oyster-beds in the North Sea, 20 fathoms deep, and extending over a length of 200 miles, and a breadth of 60 or 70—unhappily not easily dredged. Where ebb-tide leaves them dry, they instinctively keep their valves closed when the water deserts them. It is in such situations that oyster-culture can be most easily and profitably carried on. Our space will not admit of details, which we would gladly give. Various methods are adopted of preparing the artificial oyster-bed, by providing suitable solid objects for the oysters to attach themselves to. Stones are piled together, and in such a way that there are many open spaces among them; stakes are driven into the mud or sand; bundles of small sticks are fastened to stones or stakes; floors of planks are formed, at a little height above the bottom, with alleys between them, the under surface of the planks being roughened by the adze; and tiles are arranged in various ways, so as to turn to account the whole space at the disposal of the oyster-cultivator as high as the ordinary tides reach. The method must be varied in accordance with the situation, and the probable violence of winds and waves; but sheltered situations are best in all respects; and experience in France seems to prove that tiles covered with cement are preferable to everything that has yet been tried, as convenient for the cultivator, presenting a surface to which oysters readily attach themselves, and from which they can easily be removed, whilst the larger seaweeds do not grow on it so readily as on stones or wood. By the use of tiles, covered with cement, the cultivator is also able easily to remove young oysters from breeding-grounds to feeding-grounds; the best breeding-grounds being by no means those in which the oyster most rapidly attains its greatest size, and that greenish tinge which Parisian epicures so much desire to see, and which is owing to the abundant conferves and green monads of quiet muddy waters.—It has been long known that the oysters of particular localities are finer than those produced elsewhere. Nowhere, perhaps, are finer oysters produced than on some parts of the British coasts. Those of Rutupiae, now Richborough, in Kent, were highly esteemed by the Romans, whose epicurism in oysters exceeded that of modern nations.

Of the culinary uses of oysters, it is unnecessary to say anything. Raw oysters, however, are generally believed to be more nutritious and more easily digested, as to many they are more delicious, than oysters cooked in any way; and it does not appear that any such evil consequences ever ensue from eating them, as are known to ensue from eating other kinds of uncooked food. Probably no parasite capable of developing into any form injurious to the human being exists in the oyster.

The genus *Ostrea* gives its name in some zoological systems to a family *Ostreada*. The fossil species are more numerous than the recent.

The name *O.* is popularly extended to many molluscs not included among the *Ostreada*, as the Pearl-oyster (q. v.)

Oysters raised in artificial beds are called 'natives,'

and are considered very superior to those which are dredged from the natural beds; although to these last the name of 'native' would seem more appropriate than to the other. Some years ago, it was estimated that 500,000,000 oysters were consumed annually in London alone, at a cost of £100,000; but the supply has since lessened, and the price per 100 greatly increased. A large trade in oysters has sprung up in the United States; that of New York alone being estimated at \$25,000,000 annually.

Fossil Oysters.—A single species occurs in the Carboniferous Limestone, and as we rise in the crust of the earth, the genus becomes more and more common, no less than 200 species having been recorded, many of them scarcely distinguishable from the living species. The sub-genus *Gryphæa* was a free shell, with a large thick left valve and small concave right valve. Thirty species have been found in beds of the Oolite and Chalk periods. In the same beds there occurs another form of *Ostrea* with subspiral reversed umbones, to which the sub-generic name *Exogyra* has been given. Forty species of this form have been described.

OYSTERS, LAW AS TO. The rule is, that he who has the right of property in the soil or sea-shore is entitled to catch or keep and breed oysters there. But the shore below the medium line of the tides belongs to the crown, and not to any individual; and it is only by virtue of some grant from the crown that an individual or a corporation can establish an exclusive title to the sea-shore, and in such a case is exclusively entitled to any oyster-beds there. It is thus always by virtue of a grant from the crown that oyster-fisheries are claimed as the property of an individual or of a corporation. The act 31 and 32 Vict. c. 45, however, now enables the Board of Trade to grant parts of the sea-shore of Great Britain to individuals for breeding oysters and mussels, and has given new remedies for the protection of this property. The general law is as follows: Whoever steals oysters or oyster-brood from an oyster-bed which is private property, is guilty of felony; and whoever unlawfully or wilfully uses any dredge net or instrument within the limits of a private oyster-bed, for the purpose of taking oysters, though none are actually taken, is guilty of a misdemeanour, and is liable to be imprisoned for three months. But persons are not prevented from fishing for floating fish within the limits of an oyster-fishery, if they use nets adapted for floating fish. Certain statutes as old as the time of Richard II. were passed to protect oyster-brood, but these were recently repealed by the Sea Fisheries Act, 1868 (*Paterson's Fishery Laws of the United Kingdom*). Under the convention between England and France, confirmed by the statute 31 and 32 Vict. c. 45, a close season is prescribed for oyster-fishing in the seas between England and France, from 15th June to 1st September, during which time oyster-fishing boats may be boarded by officers of the coast-guard or navy; and oysters illegally caught may be seized and destroyed, and the master is liable to a penalty. In 1877 an Act was passed appointing 15th June to 4th August as a close time for fishing deep-sea oysters, and from 14th May to 4th August for other kinds, in the British seas; it also grants power to prohibit the fishing in any locality for not more than a year. The law as to oysters in Scotland is substantially the same as in England. As to Ireland, the Irish Fishery Acts give power to the Irish Fishery Inspectors to grant a licence to individuals, as is now done in England, to appropriate a certain tract of the shore for the purpose of forming oyster-beds, and thereupon the beds become private property (*Paterson's Fishery Laws* (p. 257). There

is also a close season in Ireland for oysters, like what is established under the convention with France.

OYSTER BAY, a favourite watering-place on the north coast of Long Island, New York, U. S., on a deep sheltered bay, opening into Long Island Sound, 25 miles north-east of New York city. It abounds in handsome residences and fine scenery, and offers facilities for fishing, bathing, &c. Pop. (1870) 10,595; (1880) 11,923.

OYSTER-CATCHER (*Hematopus*), a genus of birds of the family *Charadriidae* (q. v.), chiefly inhabiting sea-coasts, where they feed on molluscs, crustaceans, annelids, and other marine animals—sometimes even on small fishes. Their legs are of moderate length, like those of the plovers, and, like them, they have no hind-toe. The most remarkable generic distinction is found in the bill, which is long, strong, straight, much compressed and wedge-like towards the point. They are generally said to make use of the bill for opening the shells of oysters and other molluscs; but the late Mr James Wilson expresses a very reasonable doubt on this point. The habits of the British species (*H. ostralegus*), so far as they have been accurately observed, agree with those of the American. It is the only European

Oyster-catcher (*Hematopus ostralegus*).

species, and is common on all parts of the British coasts, on those of continental Europe, the north of Africa, and of the north of Asia. Its whole length is about 16 inches. Its finely-contrasted black and white colours have gained it the name of SEA PHE. It is most abundant on the sea-coast, but often visits inland regions, and sometimes breeds in them. It does not make a nest, but lays its eggs—usually four—on the shingly beach or bare ground. On some of the sandy flat coasts of Lincolnshire, the O. is so abundant, that a bushel of the eggs have been collected in a morning by a single fisherman. The American O. is a bird of passage, deserting the northern regions in winter. It is rather larger than the European species, and differs from it in colours, and in greater length and slenderness of bill.

OZÆNA (from the Gr. *ozo*, I smell) signifies a discharge of fetid, purulent, or sanious matter from the nostrils. It is a symptom rather than a disease, and may arise from ulceration of the membrane lining the nostrils, or from caries of the adjacent bones, and may accompany syphilitic, scorbutic, scrofulous, or cancerous affections of these or adjacent parts. A slighter form of ozæna sometimes follows chronic coryza (or cold in the head), malignant scarlatina, and erysipelas of the face. The discharge is seldom accompanied by acute pain, unless when caused by cancer;

sometimes, however, an aching is complained of. The prognosis must depend upon the nature of the disease, of which the discharge is a symptom. The treatment may be divided into the general or constitutional, and the local. The *general treatment* should consist of tonics combined with alteratives, as the preparations of bark with the alkalies, or with the mineral acids; a dry, bracing air, or a temporary removal to the seaside, is also usually of service. If the discharge arises from syphilis or scurvy, the treatment suitable to those diseases should be prescribed. The *local treatment* consists in the inhalation, once or twice a day, of the steam of boiling water, to which a little creosote or carbolic acid has been added; and in more severe cases, in the thorough syringing of the nostrils, so as to wash away all collections of matter with a copious stream of warm water, to which a little chloride of zinc has been added (about 30 minims of Burnett's solution to half a pint of water).

O'ZONE (Gr. *ozo*, I smell). It was remarked long ago that a peculiar odour was produced by the working of an electrical machine. Van-Marum found that, when electric sparks were passed through a tube containing oxygen, the gas became powerfully impregnated with this odour—which he therefore called the 'smell of electricity.' Subsequent writers attributed the phenomenon to the formation of nitric acid, due to a trace of nitrogen mixed with the oxygen; especially as the gas was found to act energetically upon mercury. Thus supposed to be explained, these curious results were soon forgotten. But in 1840, Schönbein (q. v.) with remarkable acuteness, made a closer investigation of the question, and arrived at many most curious results, all of which have not even yet been satisfactorily accounted for. The problem remains, in fact, one of the most perplexing, as well as interesting, questions imperfectly resolved in chemistry.

The earlier results of Schönbein were as follow:

(1) When water is decomposed by the voltaic current, the electrodes being of gold or platinum, the oxygen (which appears at the positive pole) possesses in a high degree the smell and the oxidising power developed by Van-Marum by means of friction-electricity. (2) When the positive electrode is formed of an oxidisable metal, these results are not observed, but the electrode is rapidly oxidised. (3) The oxygen collected at a platinum electrode retains these properties for an indefinite period, if kept in a closed vessel; but loses them by heating, by the contact of an oxidisable substance, and even by contact with such bodies as charcoal and oxide of manganese. To the substance, whatever it may be, which possesses such powerful chemical affinities, Schönbein gave the name ozone, from its peculiar smell.

In 1845, he shewed that the same substance can be produced by the action of phosphorus on moist air; and suggested that it might be a higher oxide of hydrogen.

De la Rive and Marignac shortly afterwards, repeating the experiments of Van-Marum, shewed that electric sparks produce ozone even in *pure* and *dry* oxygen; and came to the conclusion, that ozone is oxygen in an *allotropic* state, as diamond is a form of coke or charcoal.

Baumert, in 1853, endeavoured to shew that there are two kinds of ozone—one formed from pure oxygen by electric sparks, which he allowed to be allotropic oxygen; the other formed in the voltaic decomposition of water, which he endeavoured to prove to be a *teroxide* of hydrogen (HO_3). But

Andrews, in 1856, completely refuted this view, by shewing that no such oxide of hydrogen (at least in a gaseous form) is produced in the electrolysis of water; and that ozone, from whatever source obtained, is the same body; and is not a compound, but an allotropic form of oxygen.

In 1860, Andrews and Tait published the results of a series of *volumetric* experiments on this subject, which led to some remarkable conclusions—among which are the following: When the electric discharge is passed through pure oxygen, it *contracts*. If ozone be oxygen in an allotropic form, it must therefore be denser than oxygen. It was found also that a much greater amount of contraction, and a correspondingly greater quantity of ozone, were produced by a silent discharge of electricity between fine points, than by a brilliant series of sparks. The contraction due to the formation of the ozone is entirely removed by the destruction of the ozone by heat; and this process can be repeated indefinitely on the same portion of oxygen.

In attempting to determine the density of ozone, they used various bodies to take up the ozone from the oxygen containing it; and met with many very curious results. Thus, if mercury be introduced, it is immediately attacked and oxidised, and yet the oxygen *increases* in volume. If iodine be employed, it is immediately oxidised, and *no change* of volume was observed, though the apparatus would have at once rendered visible a change to the amount of ~~volume~~ of the bulk of the oxygen. By measuring the contraction produced by electricity in the oxygen, then the effect of introducing a solution of iodide of potassium, and determining the amount of oxygen taken up from the quantity of iodine set free, Andrews and Tait shewed that the density of ozone, if it be allotropic oxygen, must be practically *infinite*—i. e., that ozone must have the density of a *liquid* or a *solid* at least, although existing in the gaseous form. This conclusion is, they say, inevitable, unless we make the very improbable assumption, that when iodine, &c., are exposed to ozone, one portion of the ozone (of volume, as oxygen, equal to the volume of the whole ozone) combines with the iodine, and the other portion is restored to the form of oxygen. The paper from whose statements we have quoted concludes with the suggestion that it is *possible* that, in the formation of ozone, oxygen may be decomposed. This is, of course, contrary to all the received notions of chemistry—but such a supposition would at once reconcile all the apparently contradictory facts connected with this singular body. Soret and Von Babo have recently repeated and verified a few of these results, and the former, by using turpentine as an absorbing substance, and also by measuring its diffusion rate, has endeavoured to shew that the density of ozone is 50 per cent. greater than that of oxygen—a result on the whole consistent with the recent experiments of Brodie. Andrews has lately shewn that ozone is rapidly destroyed when shaken up with dry fragments of glass, &c. He has also proved that the effect which is (almost invariably, and sometimes in fine weather powerfully) produced by the air on what are called ozone-test papers—papers steeped in iodide of potassium (and generally spoiled by the addition of starch) which are rendered brown (or blue) by the liberation of iodine—is really due to ozone. He did so by shewing that it acts upon mercury as ozone does, and that it is destroyed by heat at the same temperature. *Nature* reported in 1880 that ozone had been liquefied, as the so-called permanent gases had been a year or two before; other experiments seem to prove that it is explosive.

P

P THE sixteenth letter of the English alphabet, was in Hebrew called *Pe*, i.e., mouth, most probably from its original form. P is the thin letter of the labial series (*p*, *b*, *f*, *v*), and is interchangeable with the other letters of the series. P, in Sanscrit, Greek, and Latin, is replaced by *f* in the Teutonic tongues. See F. Words beginning with *p* in English, and its kindred Teutonic tongues, are almost all of foreign origin (Slavic, Celtic, Latin), as *pain* (Fr. *peine*, Lat. *pœna*), *plough* (Pol. *plug*), *pit* (Lat. *puteus*, a well). The Greek prep. *apo* (Sans. *apa*) became in Lat. *ab*; Gr. *hupo*, Lat. *sub*; Sans. *upa*, Lat. *ob*; but before sharp letters, as *t* and *s*, the original *p* was retained in pronunciation, as is shewn by inscriptions (*aps-tulit*, *optinui*). There are remarkable interchanges of *p* with the sharp guttural *k* or *q*. Thus, for Lat. *quis*, *quod*, *quam*, the Oscan dialect had *pis*, *pod*, *pam*; Lat. *equus*, *coquo*, corresponded to Gr. *hippos* (Æol. *hikkos*), *pepo*; similarly, Gaelic *mac* (son), *ceathair* (Lat. *quatuor*, four), *coig* (Lat. *quinque*, five), correspond to Welsh *map*, *pedwar* (Gr. *pettores*), *pump* (Gr. *pente* or *pempe*). In Gr., *p* is sometimes replaced by *t*, as *tis*, *tessares*, for *pis*, *pettores*. In such words as *redemption*, *consumption*, *p* has been introduced as an intermediary between the incompatible sounds *m* and *t*. The initial *p* of Latin words has for the most part passed into French unaltered; in other positions, *p* has become *v*; thus, Fr. *évêque*, *cheveu*, *décevoir*, *pauvre*, from Lat. *episcopus*, *capillus*, *decipere*, *pauper*.

PA'CA (*Coelogenys*), a genus of rodent quadrupeds, allied to the agoutis, caviæ, and capybara, and inhabiting Brazil, Guiana, and some of the West India Islands. The dentition very nearly resembles that of the agoutia. The cheek-bones are prodigiously developed, in a way of which no example exists in any other mammalian animal, so that the zygomatic arches enclose a large hollow space, whilst the bone also descends to an unusual depth from the arch, even below the lower jaw-bone. Within this structure, which gives an extraordinary breadth and peculiar aspect to the face, is a sac in each cheek, opening in front, and lined with a fold of the skin of the face. The whole of this seems to be intended to preserve the true cheek-pouches from external shocks. The cheek-pouches open from the mouth in the usual way, and are capable of very great distention. The lip is cleft; the ears are small; the eyes are large and full; the neck is short; the tail is a mere tubercle; the feet have each five toes; the legs are thick; the back is rounded. The form and gait are clumsy, yet the *P.* (*C. paca*) is very quick and active. It lives in moist grounds, burrowing like the rabbit, but not so deeply; its burrow, however, is always provided with three openings. It feeds on vegetable substances, and often does great damage to plantations of sugarcane. It is one of the largest rodents, being about two feet long. It is generally of a dark brown

colour, with four rows of white spots along the sides, the throat and belly white. A lighter-coloured species has been described, but is perhaps a mere variety. The flesh of the *P.* is much esteemed, and is very fat.

PACAY (*Prosopis dulcis*), a tree of the natural order *Leguminosæ*, sub-order *Mimosæ*; a native of Peru, of rather large size, with a broad head; producing pods from twenty inches to two feet long, which contain black seeds imbedded in a sweet flaky substance as white as snow. This flaky substance is used as an article of food and much relished by the Peruvians.

PACE (Lat. *passus*), in its modern acception, is the distance, when the legs are extended in walking, between the heel of one foot and that of the other. Among disciplined men the pace becomes of constant length, and as such is of the utmost value in determining military movements, the relative distances of corps and men being fixed by the number of paces marched, and so on. The pace in the British army is $2\frac{1}{4}$ feet for ordinary marching, and 3 feet for 'double-quick' or running time.—With the Romans, the pace had a different signification, and it is important to bear the distinction in mind, when reading of distances in Latin works; the single extension of the legs was not with them a pace, (*passus*), but a step (*gradus*); their pace (*passus*) being the interval between the mark of a heel and the next mark of the same heel, or a double step. This pace was equivalent to 4.84 English feet. The pace was the Roman unit in itinerary measure; the mile being 1000 paces, or 5000 Roman feet, equal to .917 of an English mile. See **MILE**. Whether measurements were effected by actually counting the paces, or by the time occupied, is not clear; but either method would, with disciplined troops, give a safe result.

In the middle ages, writers confuse accounts of distances by allusion to a geometrical pace, a measure which varied with different authors.

PACHO'MIUS, an Egyptian monk of the 4th c., is held in high estimation by the Roman Catholic church, as being the first to substitute for the free asceticism of the solitary recluse, a regular cenobitic system. He was born towards the close of the 3d c., was brought up as a pagan, but converted to Christianity by the kindness of certain Christians whom he encountered at Thebes. About 340 A. D., at Tabenna, an island in the Nile, he founded the first monastic institution. The members agreed to follow certain rules of life and conduct drawn up by P., and to subject themselves to his control and visitation. He also established the first convent for nuns, which was under the presidency of his sister, and laboured with so much diligence and zeal, that at his death, according to Palladius, not fewer than 7000 monks and nuns were under his inspection. The various writings extant under the name of P. are—*Regulæ Monasticæ* (of doubtful genuineness), *Monita*, *SS. P.P. Pachomii et Theodori*,

Epistola et Verba Mystica (a farrago of unintelligible allegory), and *Præcepta S. Pachomii*.

PACHYDERMATA (Gr. thick-skins), in the system of Cuvier, an order of Mammalia, including part of the *Bruta* (Rhinoceros, Elephant), and all the *Beluæ* (Horse, Hippopotamus, Tapir, Hog, &c.) of Linnaeus, besides one genus (*Hyrax* or *Daman*) of the Linnaean *Glires*. But subsequent investigation has demonstrated so close an alliance to be unnatural, and probably no Cuvierian order has been so thoroughly broken up. The elephants and hyrax now form two small independent orders—*Proboscidea* and *Hyracoidea*. The pigs and hippopotami form the non-ruminant division of the ungulate sub-order—*Artiodactyla* (q. v.), while the closely-allied tapir, rhinoceros, and horse represent the perissodactyle ungulates. As defined by Cuvier, the order consists of those hoofed mammalia (*Ungulata*) which are not ruminants; all of which possess, as a more positive character, a remarkable thickness of skin. This order he divides into three sections—(1.) *Proboscidea*, having a prolonged snout or proboscis, through which the nostrils pass as elongated tubes, a powerful organ of prehension, and a delicate organ of touch, and having also five toes on each foot, enclosed in a very firm horny skin; (2.) *Ordinaria*, destitute of proboscis, although in some (Tapirs), there is such an elongation of the upper lip and nostrils as approximates to it; and the nose is employed by hogs, &c., in seeking their food, not only as an organ of smell, but as an instrument for turning up the ground, and as an organ of touch; the number of toes varies, four, three, or two on each foot; those with an even number of toes, having in the cleft foot a resemblance to the *Ruminantia*; and (3.) *Solidungula*, in which the foot has but one apparent toe, enclosed in a hoof. Some naturalists have thought it better to separate the *Solidungula* or *Equidae* (q. v.) from the P., as a distinct order; whilst others have enlarged instead of restricting the limits of the order, by adding, as a fourth section, the *Herbivorous Cetacea*, now known as *Sirenia*.

Those P. which have a number of toes differ completely from the mammalia having claws (*Ungiculata*) in their inability to bend their toes in order to seize any object. Some of the *Edentata* have very large hoof-like claws, but this difference still subsists. The fore-limbs of the P. are also incapable of any rotatory motion, serving for support and locomotion only, not at all for prehension; the metatarsal and metacarpal bones being consolidated as in the *Ruminantia*, and they have no clavicles.

The largest terrestrial mammalia belong to this order. Most of the P. are of large size, although the damans are a remarkable exception, and some of the hog family are also comparatively small. Most of them have a clumsy form, with a slow and awkward gait; but they are capable of activity beyond what might be supposed, and sometimes move at a pretty rapid pace. Gracefulness and fleetness are characteristics of the otherwise exceptional *Solidungula*. The P. *Ordinaria* have generally great strength, and the larger ones push their way through the entangled thickets of tropical forests, bending or breaking the lianas, small trees, and branches which oppose their progress, their thick hides resisting the spines and broken branches by which the skins of other animals would be pierced. The horse and other *Solidungula* are not inhabitants of forests and jungles, but generally of grassy plains, and their hides are much less thick and hard than those of most of the Pachydermata.

The physiognomy of the P. in general is rather dull and unexpressive, the eyes being small, and having that character of which a familiar example

is found in the common hog. When enraged, however, they manifest their fierceness in their eyes; and although, in general, mild and gentle, they are capable of being aroused to great fury.

The skeleton of the P. *Ordinaria* and *Proboscidea* is strong and massive; the neck short, the processes of its vertebrae strongly developed; the skull affording a large surface for the muscles which support and move it.

The P. generally feed on vegetable substances. Some are omnivorous. The digestive organs are more simple than in the *Ruminantia*, but exhibit considerable diversity. The stomach is simple in some, and in others is more or less completely divided into sacs, approaching to one of the most remarkable characters of the *Ruminantia*. The intestines are generally longer than in the *Ruminantia*. The dentition exhibits considerable diversity; the adaptation to vegetable food being the most prevalent character. The most important peculiarities of the dentition and digestive organs are noticed in the articles on particular families and genera.

PACIFIC OCEAN, the largest of the five great Oceans (see OCEAN), lies between America on the east, and Asia, Malaisia, and Australasia on the west. The name 'Pacific,' given to it by Magellan, the first European navigator who traversed its wide expanse, is doubtless very appropriate to certain portions of this ocean; but, as a whole, its special claims to the epithet are at the least doubtful, though the name has by long usage become too well established to be easily supplanted by any other.

The greatest length of the P. O. from the Arctic (at Behring's Strait) to the Antarctic circles is 9200 miles, and its greatest breadth, along the parallel of latitude 5° N., about 10,300 miles; while its area may be roughly estimated at 80,000,000 English square miles, or about $\frac{1}{4}$ ths of the whole surface of the earth. Its form is rhomboidal, with one corner incomplete (at the south), and its surface is studded with numberless islands, either scattered or in groups; these, however, are chiefly confined to the western side. Along the whole eastern side, there is a belt of sea of varying width, which, with a very few exceptions, is wholly free from islands. The deepest sounding yet found (in N. lat. 11° 24', E. long. 143° 16') in the P. O. is 26,850 feet, or above 5 miles—nearly equal to the height of the highest mountain on the globe.

The coasts of the P. O. present a general resemblance to those of the Atlantic, and the similarity in the outline of the western coasts of each is even striking, especially north of the equator; but the shores of the former, unlike those of the latter, are sinuous, and, excepting the north-east coast of Asia, little indented with inlets. The shore on the American side is bold and rocky, while that of Asia varies much in character.

Though the P. O. is by far the largest of the five great oceans, being about equal to the other four in extent, the proportion of land drained into it is comparatively insignificant. Its basin includes only the narrow strip of the American continent to the west of the Andes and Rocky Mountains; Melanesia (with the exception of almost the whole of Australia), which contains few rivers, and none of them of large size; the Indo-Chinese states, China Proper, with the east part of Mongolia, and Manchuria in the Asiatic continent.

Winds.—The trade-winds of the Pacific have certain peculiarities, which have only lately been discovered. In general, they are not found to preserve their peculiar characteristics except within certain limits, thus, the south-east trades are found to blow steadily only between 92° and 140° of west longitude; while the north-east trades

are similarly fluctuating, except between long. 115° W. and 214° W. Beyond these limits, their action is in whole or in part neutralised by the monsoons and other periodical winds peculiar to the tropical regions of the Pacific. In Polynesia, especially near the New Hebrides group, hurricanes are of frequent occurrence from November to April, but they exhibit few of the terrible characteristics which distinguish the hurricanes of the West Indies and Indian Ocean. North and south of the tropical zone, the winds exhibit little periodicity, being found to blow from all parts of the compass at any given season of the year, though a general westerly direction is most frequent among them. On the coast of Patagonia and at Cape Horn, west winds prevail during the greater part of the year, while in the Sea of Okhotsk they are of rare occurrence. The frightful Typhoon (q. v.) is the terror of mariners in the Chinese seas, and may occur at all seasons of the year. There are many other winds and storms, such as white squalls, cyclones, 'tempestades,' &c., which are confined to particular localities, and will be found noticed under other heads, and also under STORMS.

Currents.—The currents of the P. O., though less marked in character and effects than those of the Atlantic, are yet of sufficient importance to require a brief notice. The *Southern Pacific current* takes its rise south of Van Diemen's Land, and flows eastward at the rate of half a mile per hour, dividing into two branches about long. 98° W., the northern branch or *Current of Mentor* turning northward, and gradually losing itself in the counter equatorial current; the southern branch continuing its eastward course till it is subdivided by the opposition of Cape Horn into two branches, one of which, the *cold Current of Peru* or *Humboldt's current*, advances northward along the west coast of South America, becoming finally absorbed in the equatorial current; the other washing the coast of Brazil, and becoming an Atlantic current. The P. O., like the Atlantic, also possesses its equatorial current, separated into a northern and southern current by the equatorial counter-current. It sweeps across the whole ocean from east to west. Two subdivisions of the southern current, called respectively the 'current of Rossel' and the 'warm current of Australia,' flow, the one through the Polynesian Archipelago to New Guinea, and the other along the east coast of Australia. The northern equatorial current, after reaching the coast of Asia, turns north-east, washing the shores of China and Japan, under the name of the *Black or Japan current*; it then sends off a branch along the coast of Kamohatka, and advances eastward till it becomes lost on the north-west coast of North America. There are other minor currents, the most remarkable of which is that of Flouvier, which describes a kind of irregular circle with a radius of about 240 miles. It is situated in lat. 25°–40° N., and long. 133°–155° W. All these currents have their corresponding counter-currents.

There are two 'sargassoes' or weedy seas of considerable extent in the P. O., one lying 15° east-south-east of New Zealand; the other, and by far the larger, about 15° west of San Francisco in California. There is also a large region lying nearly half-way between Cape Horn and New Zealand, which seems to correspond to the deserts on land, as mariners report it almost wholly destitute of any signs of life either in sea or air.

History.—The existence of this ocean first became known to Europeans through Columbus, who had received accounts of it from some of the natives of America, though it was first seen by Balboa, September 29, 1513, and first traversed by Magellan

eight years afterwards; but its size, limits, and the number and position of its islands, &c., were little known till long afterwards. Captain Cook deserves the first place among the investigators of the P. O.; and after him come Anson, the two Bougainvilles, La Perouse, Carteret, Vancouver, Krusenstern, Kotzebue, &c. But the most thoroughly scientific examination of its physical condition is that accomplished by the *Challenger Expedition* of 1873–76.

PACINIAN CORPUSCLES are very remarkable structures appended to the nerves. In the human subject, they are found in great numbers in connection with the nerves of the hand and foot, and sparingly on other spinal nerves, and on the plexuses of the sympathetic, but never on nerves of motion. They always present a *proximal end*, attached to the nerves by a stalk of fibrous tissue prolonged from the neurilemma, and occasionally one-tenth of an inch long; and a *distal end*, lying free in the connective or areolar tissue. In the human subject, the corpuscles vary in length from one-twentieth to one-tenth of an inch. They are usually seen very readily in the mesentery of the cat, appearing as pellucid oval grains, rather smaller than hemp-seed. The microscopic examination of these bodies discloses an internal structure of a very remarkable kind. They consist, first, of a series of membranous capsules, from thirty to sixty or more in number, enclosed one within the other; and secondly, of a single nervous fibre, of the tubular kind, enclosed in the stalk, and advancing to the central capsule, which it traverses from beginning to end, and where it finally terminates in a fixed swollen extremity. The ten or fifteen innermost capsules are in contact with one another, while the rest are separated by a clear space containing fluid, which is so abundant as to constitute far the largest portion of the bulk of the entire corpuscle. Such are the views of Pacini (as given in his *Nuovi Organi Scoperte nel Corpo Umano*, 1840), who is usually regarded as their discoverer, although they had been noticed and roughly described nearly a century before by Vater, of Henle, and of Todd and Bowman; but later observations made by Huxley, Leydig, Kölliker, and others, shew that the question of their true nature is still an open one. Huxley asserts that their central portion is solid, and not hollow; that in birds, and in the human hand, there is no fluid between the laminae—and indeed, that the laminae themselves have no real existence—the Pacinian corpuscle being merely a solid mass of connective tissue (a thickened process of the neurilemma of the nerve to which it is attached), whose *apparent lamination* depends on the regular disposition of its elastic elements. For a full description of the present state of knowledge as to the structure and function of these remarkable nerve-endings, see Quain's *Anatomy*, or any recent standard work on anatomy or histology.

PACKFONG, or PETO'NG, a Chinese alloy or white metal, consisting of arsenic and copper. It is formed by putting two parts of arsenic in a crucible with five parts of copper turnings, or finely divided copper; the arsenic and copper require to be placed in alternate layers, and the whole is covered with a layer of common salt, and pressed down. When melted, the alloy contains nearly the whole of the arsenic, and is yellowish-white in colour when in the rough state, but takes a fine white polish resembling silver. It is not very ductile, and cannot be fused without decomposition, as the arsenic is easily dissipated. It was formerly much used in this country, as well as China and India, for making the pans of small scales, dial-plates, and a variety of other articles requiring nicety of make, such as

graduated scales for philosophical instruments. It is probably never imported now, the nickel alloys of Europe having quite superseded its use; in China, however, it is still extensively employed.

PACKHORSE, a horse employed in the carriage of goods, which are either fastened on its back in bundles, or, if weighty, are placed in panniers, slung one on each side across the horse's back. The saddle to which the bundles were fastened consisted of two pieces of wood, curved so as to fit the horse's back, and joined together at the ends by other two straight pieces. This frame was well padded underneath, to prevent injury to the horse's back, and was firmly fastened by a girth. To each side of the saddle, a strong hook was attached, for the purpose of carrying packages, panniers, &c. Panniers were sometimes simply slung across the horse's back with

Packhorse and Panniers.

a pad under the band. The panniers were wicker baskets, and of various shapes, according to the nature of their usual contents, being sometimes long and narrow, but most generally having a length of three feet or upwards, a depth of about two-thirds of the length, and a width of from one to two feet (see fig.). The packhorse with panniers was at one time in general use for carrying merchandise, and for those agricultural operations for which the horse and cart are now employed; and in the mountainous regions of Spain and Austria, and in other parts of the world, it still forms the sole medium for transport; though the mule has, especially in Europe, been substituted for the horse.

An army requires to be accompanied by several thousand pack-animals, sometimes horses, but preferably mules; and in Asia, commonly camels, or even elephants. Pack-saddles are variously fitted, according to the objects to be carried: some for provisions or ammunition; others for carrying wounded men, tents, and, in mountain-warfare, even small cannon. In battle, the immediate reserves of small-arm ammunition are borne in the rear of divisions by pack-animals; the heavy reserves being in wagons between the army and its base of operations.

PACOURY-UVA, a sweet and delicious Brazilian fruit, a large berry, produced by the *Platonia insignis*, a tree of the natural order *Clusiaceæ*. The seeds have the taste of almonds.

PACTOLUS, anciently the name of a small brook of Lydia, in Asia Minor, which rises on the northern slope of Mount Tmolus (modern *Buz Dagh*), flows north past Sardis (*Sart*), and empties itself into the Hermus (*Kodus*). It is never more than ten feet broad, and one foot deep. The sands or mud of P. were long famous in antiquity for the particles of gold dust which they contained, and which are supposed to have been carried down by

its waters from the bosom of Tmolus—a hill rich in metals. The collection of these particles, according to legend, was the source of Croesus's vast wealth. But as early even as the time of Strabo, P. had ceased to yield any of the precious dust. The brook is now called *Sarabat*.

PACTUM ILLICITUM is, in the law of Scotland, a contract or agreement for some illegal purpose, i. e., a purpose either expressly prohibited by statute, or by the general policy of the law. Thus, an immoral contract between a man and woman would be held void on the ground, that the law discountenances practices *contra bonos mores*. A contract between a client and agent, called a *pactum de quota litis*, whereby a share of the property which is the subject of litigation is given to the agent instead of his usual fees, is void in most cases; though it is often difficult to determine what contracts fall within this rule. The courts, however, have construed very jealously every contract which tends to corrupt the administration of the law, and hence an agreement between a town and country agent to divide the profits has been held a *pactum illicitum*. So agreements by a client to give an excessive sum to his law-agent as a gift have been often set aside.—In England, similar doctrines prevail, though the phrase *pactum illicitum*, which was borrowed from the Roman law, is not used, contracts of this description being technically described as illegal contracts.

PADANG, the capital of the Dutch government of the west coast of Sumatra, is situated in 0° 59' 30" S. lat., and 100° 20' 30" E. long., and has about 12,000 inhabitants. The Padang flows through the town, but is only navigable for small vessels, the larger requiring to anchor in the roadstead, about three miles distant. On the left bank, stand the houses of the natives, unsightly bamboo erections, elevated about eight feet from the ground by posts of the cocoa-nut tree, and covered with leaves. The government buildings, houses of the Europeans and Chinese, &c., are on the right, and mostly built of wood or stone, and roofed with tile. P. is picturesquely enclosed by a semicircle of mountains, behind which rises a loftier chain, two being volcanoes. There are a Protestant church, a Roman Catholic church, flourishing schools, a fort, military hospital, government workshops, large warehouses, &c. An agent of the Netherlands Trading Company (q. v.) resides at Padang. Being the centre of the exports and imports of Sumatra's west coast, P. has a lively trade, not only with Java, the other islands of the Eastern Archipelago, and Europe, but also with the interior of the island.

The climate is considered healthy, although the heat is great. Colonel Nahuys found the thermometer range from 70° to 80° at 6 A.M., from 82° to 88° at noon, 84° to 90° at 2 P.M., 78° to 84° at 6 P.M., and from 72° to 80° at 10 in the evening.

The governor resides at a country-house about two and a half miles above P., and rules over a territory stretching from the south-east corner of the island. It comprises the greater part of Sumatra, and is divided into the residencies of Lower Padang, Upper Padang, Tapanceli (Tapanuli), Bencoolen, the Lampongs, and Palembang. The total population of the Dutch possessions is about 2,000,000, besides 3000 Chinese, and 2000 Europeans. This is irrespective of Atcheen (q. v.).

Lower Padang was the first district of the west coast of Sumatra which submitted to the Dutch, who had formed a settlement at Padang as early as 1660, and by repeated wars, gradually extended their territory.

Upper Padang lies to the north-west of the lower

PADDLE—PADDLE-WHEEL.

province, from which it is separated by a chain of lofty mountains, some of which, as the Singalang, Merapie, and Sago, attain to nearly 10,000 feet in height; Merapie being an active volcano, the last eruptions of which were in 1845 and 1855, though it sent forth volumes of smoke in 1861. This residency possesses the most lovely districts of the island, or of any tropic land, the mountain slopes being studded with villages, rice-fields, cocoa-nut and coffee trees, of which last, it is calculated that there are 32,000,000 in Upper Padang. In addition to the coffee-culture, gambier, cassia, pepper, ratans, indigo, caoutchouc, &c., are largely produced, and gold, iron, copper, lead, and quicksilver are found. In the district of Tanah Datar is the town of Paggeroejong, formerly the capital of the powerful kingdom of Menangkabo, and the residence of the king.

Tapanoei, the remaining residency under the government of Sumatra's west coast, lies north-west from Upper Padang. The independent spirit of the inland natives has caused the Netherlands much trouble, but each fresh outbreak only extends their territory and power further into the interior, and towards the north-west of the island.

PADDLE, probably the precursor of the OAR (q. v.), and still its substitute among barbarous nations, is a wooden implement, consisting of a wide flat blade with a short handle, by means of which the operator spoons the water towards him. In canoes for only one sitter, a double paddle is generally used, which is dipped alternately on either side: the inhabitants of Greenland are especially skilful in this operation. The action of the paddle is the same as that of the oar. The paddle has, however, one advantage

Paddle. Double Paddle.

—viz., that the rower faces the bow of his boat, and therefore sees what is before him. In threading narrow streams, &c., this is an appreciable gain.

PADDLE-WHEEL—one of the appliances in steam-vessels by which the power of the engine is made to act upon the water and produce locomotion—is a skeleton wheel of iron, on the outer portion of whose radii flat boards, called floats or paddles, are fixed, which beat upon the water, and produce, continuously, the same effect as is given, in an intermittent manner, by the blades of oars. The use of paddle-wheels in conjunction with steam as a motive-power dates from about the commencement of the present century, but the employment of the paddle-wheel itself is as ancient as the time of the Egyptians. A specimen is also known to have been tried in Spain in the 16th century.

The fig. shews the usual form of paddle-wheel, that called the radial, in which the floats are fixed. It will be seen that a certain loss of power is involved, as the full force of the engine on the water is only experienced when the float is vertical, and as on entering and leaving the water the power is mainly employed in depressing or lifting the particles of water. This objection has great force at the moment of starting, or when progress is very slow, as is illustrated by the small power a paddle-steamer evinces when trying to tug a stranded vessel off a sandbank; but when in full progress, the action is less impeded by this circumstance, the water in front of the wheel being depressed, and

that abaft being thrown into the form of a wave. The extent of the immersion much influences the economy of power, as will be readily understood if

Ordinary Paddle-wheel.

the consequences of immersion up to the centre of the wheel be imagined. An immersion somewhat over the top of the lowest float is about the most advantageous, and in order that the floats may be as nearly as possible vertical when they strike the water, it is advisable to give the wheel as large a diameter as possible, and to place the axis at the highest available point in the vessel.

To overcome the drawbacks to the radial wheel, Elijah Galloway patented, in 1829, the *Feathering Paddle-wheel*, in which the floats are mounted

Feathering Paddle-wheel.

on axes, and are connected by rods with a common centre, which revolves upon a pin placed eccentrically to the axis of the paddle-wheel. By this method, the floats are kept, while immersed, at right angles to the surface of the water. So long as the water is smooth the gain is great, consequently feathered floats are much used in river-steamers; but for ocean-steamers the liability to derangement, perhaps at a critical period, is a great objection to their use.

The paddle-wheel, in revolving, imparts both a forward velocity to the vessel and a backward velocity to the water. The latter is called the *slip*, and sometimes bears a very large and wasteful proportion to the former. The absolute velocity of the paddle floats is equal to the sum of the slip and the forward motion of the ship, so that the wheel always revolves faster than the ship makes way.

PADDY, or **PADDIE**, the name commonly applied in India to rice in the husk. It is the Tamil and the Malay name. See **RICE**.

PADELLA (Ital. a frying-pan; plur. *padelle*), a shallow vessel of metal or earthenware used in illuminations. The illumination of St Peter's at Rome, and other large buildings in Italy, is effected by the tasteful arrangement of large numbers of these little pans, which are converted into lamps by partly filling them with tallow or other grease, and placing a wick in the centre. This mode of illumination was first adopted on a large scale in Great Britain on the occasion of the marriage of the Prince of Wales with the Princess Alexandra, when the inhabitants of Edinburgh produced by this means a most magnificent illumination of their city.

PADERBORN, the chief town of a district in the Prussian province of Westphalia, situated in 51° 43' N. lat., and 8° 45' E. long., in a pleasant and fruitful district, is built at the source of the Pader, which bursts forth from below the cathedral with sufficient force to drive mills within 20 paces of its point of exit. Pop. (1880) 14,689. P. has narrow, dark, old-fashioned streets, presenting no special attractions, although it has some interesting buildings, as, for instance, the fine old cathedral, completed in 1143, with its two magnificent façades, and containing the silver coffin in which are deposited the remains of St Liborius. It is the seat of a bishop and chapter, and of an administrative court. The manufactures of P., which are not very considerable, include tobacco, starch, hats, and wax-cloths, and there are several breweries, distilleries, and sugar-refineries in the town, which carries on a considerable trade in cattle, corn, and oils. P. is one of the important stations on the Great Westphalia Railway. P., which ranked till 1803 as a free imperial bishopric, owes its foundation to Charlemagne, who nominated the first bishop in 795. Several diets were held during the middle ages at P., which at that period ranked as one of the most flourishing of the Hanseatic Cities, while it was also numbered among the Free Imperial Cities. In 1604, it was forcibly deprived by the prince-bishop, Theodor of Fürstenburg, of many of the special rights and prerogatives which it had enjoyed since its foundation, and compelled to acknowledge the Roman Catholic as the predominant church, in the place of Protestantism, which had been established during the time of Luther. In 1803, P. was attached as an hereditary principality to Prussia, and after being for a time incorporated in the kingdom of Westphalia, was restored to Prussia in 1813, and incorporated in the Westphalian circle of Minden.

PADIHAM, a large chapelry and township, in the higher division of the hundred of Blackburn, seated on an eminence springing from the north bank of the Calder, and reached by the Rose Grove station of the Lancashire and Yorkshire Railway, and also by the Leeds and Liverpool Canal. It is about 9 miles north-east of Blackburn. The cotton trade employs a great proportion of the population—with Hapton (1881) 8983—but coal-mines and extensive quarries also add to industrial activity and the prosperity of P.; which has been greatly improved in appearance recently by several new streets.

PADILLA, **JUAN DE**, one of the most popular heroes in Spanish history, was a scion of a Toledan family, and was appointed by the Emperor Charles V. military commandant of Saragossa. While he was so employed, a formidable rebellion, caused by the excessive taxes which the emperor imposed on the Spaniards, to defray the cost of his various wars in Italy, Germany, and the Low Countries, broke out

among the towns (*comunidades*) of Castile, and the rebels, who were known as *comuneros*, called upon P. to put himself at their head. The introduction of the religious element into the quarrel tended greatly to strengthen the insurgents, and for an instant P. was the ruler of Spain, and formed a new junta to carry on the government. He was successful in a number of enterprises undertaken against the royalist party; but on 23d April 1521, was completely beaten by the royalists at Villaloe. This conflict decided the fate of the rebellion and of P. himself, who was taken prisoner, and next day beheaded.

His wife, **DONA MARIA DE PACHECO**, rallied the wrecks of the rebel army, and for a long time held Toledo against the royalist besieging army, and after its fall, retired to Portugal, where she died soon afterwards. With P. and his wife expired the last remnant of the ancient freedom of Spain. Numerous poems and dramas celebrate their deeds.

PADISHAH, in Turkish **PADISHAH** (Persian *padi*, protector or throne, *shah*, prince), one of the titles of the Sultan of the Ottoman Empire, and of the Shah of Persia. Formerly, this title was accorded only to the kings of France among European monarchs, the others being called *Kral*, king. It was subsequently allowed to the Emperor of Austria, and still later, by a special article in the treaty of Kutahuk-Kainardji (10th January 1775), to the autocrat of All the Russias. Of late it has been accorded to the monarchs of all the great European nations, and even to those of secondary states.

PADUA (Ital. *Padova*), capital of the province of the same name in Northern Italy, stands on a beautiful plain on the Bacchiglione, 23 miles by railway west-south-west of Venice. It is surrounded by walls and ditches, and is fortified by bastions. Its houses are lofty, supported for the most part on long rows of arches, generally pointed; and most of its streets, especially in the older quarters, are narrow, dark, dirty, and ill-paved. There are, however, several handsome gates, as those of San Giovanni, Savonarolo, and Falconetto; a number of fine squares, of which the Prato della Valle is the largest and the finest, and is surrounded by a stream, and planted with trees; and several magnificent buildings. Of these, the Café Pedrocchi is esteemed the finest edifice of the kind in Italy. Portions of a Roman edifice were discovered while the foundations of this building were being made, and the marbles found now adorn the pavement, &c., of the *salone*. The Palazzo della Municipalità, built 1172—1219, is the most peculiar and most national in the city. It is an immense building, forming one side of the market-place, rests wholly on arches, and is surrounded by a loggia (q. v.). Its east end is covered with shields and armorial bearings, and its roof is said to be the largest unsupported by pillars in the world. Its hall is 267½ feet long, and 89 feet wide, is covered with mystical and metaphorical paintings, and contains a monument of Livy, the Roman historian, and a bust of Belzoni, the traveller, both natives of this city. The other chief edifices are the cathedral, the church of Sant' Antonio, a beautiful building in the Pointed style, with several Byzantine features, and remarkably rich and splendid in its internal decorations; and the churches of San Giorgio and of Santa Giustina; all of them richly decorated with paintings, sculptures, &c. The university of P., the most famous establishment in the city, was celebrated as early as the year 1221. It embraces 61 professors and other teachers, and is attended by about 1000 students. Connected with the university are an anatomical

theatre and a botanic garden, both dating from the 16th c., and each the first of its kind in Europe. There is also a museum of natural history, an observatory, a chemical laboratory, and a library of 120,000 volumes and 1800 manuscripts. There are also numerous palaces, theatres, and hospitals. Pop. (1881) 72,174.

P., the Roman *Patavium*, is one of the most ancient towns of Italy. According to a wide-spread belief of antiquity, alluded to by Virgil, it was founded by the Trojan chief Antenor, but we really know nothing of its history until it became a Roman town. During the first centuries of the empire, it was the most flourishing city in the north of Italy, on account of its great woollen manufactures, and could return to the census more persons wealthy enough to be ranked as *equites* than any other place except Rome. But in 452 Attila utterly razed it to the ground. It was, however, rebuilt by Narses, again destroyed by the Lombards, but once again rose from its ashes, and became a very famous city in the middle ages. It fell into the hands of the Carrara family in 1318, and in 1405 it was conquered by Venice, the fortunes of which it has since shared.

PADUCAH, a city of Kentucky, U. S., on the south bank of the Ohio River, just below the mouth of the Tennessee River, 322 miles below Louisville. It is the entrepôt of a fertile country, and has a large trade by the rivers, the Louisville, Paducah, and South-western, and the Paducah and Memphis Railways. It contains county buildings, 4 banks, 3 shipyards, steam saw-mills, extensive manufacturing establishments, and 15 churches. Pop. (1880) 8376.

PÆAN (of doubtful etymology), the name given by the ancient Greeks to a kind of lyric poetry originally connected with the worship of Apollo. The oldest peans, as we learn from Homer, appear to have been either hymns, addressed to that deity for the purpose of appeasing his wrath (*Iliad*, i. 473), or thanksgiving odes, sung after danger was over and glory won (*Iliad*, xxiii. 391). Nevertheless, at a later period, they were addressed to other deities also. Thus, according to Xenophon, the Lacedæmonians sung a pean to Poseidon after an earthquake, and the Greek army in Asia one to Zeus.

PÆDO-BAPTISM. See BAPTISM, INFANT.

PÆONY (*Pæonia*), a genus of plants of the natural order *Ranunculaceæ*; having large flowers, with five persistent, unequal, leafy, and somewhat leathery sepals, 5–10 petals, many stamens, and 2–5 germens, which are crowned with a fleshy recurved stigma. The leaves are compound, the leaflets often variously and irregularly divided. The fibres of the root are often thickened into tubers. The species are large herbaceous perennials, or rarely half-shrubby; natives of Europe, Asia, and the north-west of America. None of them are truly indigenous in Britain, although one (*P. corallina*) has found admittance into the English Flora. On account of the beauty of their flowers, some of them are much cultivated in gardens, particularly the COMMON P. (*P. officinalis*), a native of the mountain-woods of the south of Europe, with carmine or blood-red flowers. A variety with double flowers is common.—The WHITE P. (*P. albiflora*) is another favourite species. It is a native of the central parts of Asia. Its flowers are fragrant.—The TREE P., CHINESE P., or MOUTAN (*P. Moutan*), is a half-shrubby plant, a native of China and Japan. In favourable circumstances, it attains a very large size, and a height of twelve feet or more. It has been long cultivated in China and Japan; and is

now also a favourite ornamental plant in the south of Europe, and in the south of England and Ireland; but the late spring-frosts of most parts of Britain are injurious to it, although it can bear severe frost in winter, when vegetation is at a stand. It flowers in spring. The varieties in cultivation are numerous. It is propagated by cuttings, and also by grafting. Its germens are surrounded by a cup-shaped lacinated membrane.—The roots of most of the pæonies have a nauseous smell when fresh, and those of the Common P. were in high repute among the ancients as an antispasmodic—hence the name Pæony, from *Paion*, a Greek name of Apollo, the god of medicine—but their medicinal properties are now utterly disregarded. The globose, shining black seeds of pæonies were formerly, in some countries, strung into necklaces, and hung round the necks of children, as *anodyne necklaces*, to facilitate dentition. The Daurians and Mongolians use the root of *P. albiflora* in their soups, and grind the seeds to mix with their tea.

PÆSTUM, anciently a Greek city of Lucania, in Southern Italy, in the present province of Salerno, on the *Sinus Pastanus*, now the Gulf of Salerno, and not far from Mount Alburnus. It was founded by the Troezenians and the Sybarites, some time between 650 and 610 B.C., and was originally called Poseidonia (of which *Pæstum* is believed to be a Latin corruption), in honour of Poseidon (Neptune). It was subdued by the Samnites of Lucania, and slowly declined in prosperity after it fell into the hands of the Romans, who established a colony here about 273 B.C. The Latin poets celebrate the beauty and fragrance of its flowers, and particularly of its roses, which bloomed twice a year. Wild roses, it is said, still grow among its ruins, which retain their ancient property, and flower regularly both in May and November. P. was burned by the Saracens in the 10th c., and there is now only a small village called Pesto, in a marshy, unhealthy, and desolate district; but the ancient greatness of the city is indicated by the ruins of temples and other buildings. These appear to have been first noticed in the early part of the 18th c., by a certain Count Gazola, in the service of the king of Naples; they were next described by Antonini, in a work on the topography of Lucania (1745), and have since been visited by travellers from all parts of Europe.

PAGANINI, NICOLÒ, a famous violinist, son of a commission-broker at Genoa, where he was born in 1784. His musical talent shewed itself in his childhood; in his ninth year, he had instructions from Costa at Genoa, and afterwards from Rolla at Parma, and from Ghiretti. In 1801, he began his professional tours in Italy; in 1823, he created a great sensation on appearing for the first time in the principal towns of Germany; and in 1831, his violin-playing created an equal *furor* in Paris and London. His mastery over the violin has never been equalled, but he was too much addicted to using it in mere feats of musical legerdemain, such as his celebrated performance on a single string. His execution on the guitar was also very remarkable; for four years he made that instrument his constant study. P. died at Nice in 1840, leaving a large fortune.

PAGANISM, another name for Heathenism or Polytheism. The word is derived from the Latin *paganus*, a designation of the inhabitants of the country (*pagus*), in contradistinction to the inhabitants of towns, the more educated and civilised inhabitants of towns having been the first generally to embrace Christianity, whilst the old polytheism lingered more in remote rural districts.

PAGE (derivation variously assigned to Gr. *pais*, a boy, and Lat. *pagus*, a village), a youth employed in the service of a royal or noble personage. The practice of employing youths of noble birth in personal attendance on the sovereign, existed in early times among the Persians, and was revived in the middle ages under feudal and chivalric usages. The young nobleman passed in courts and castles through the degree of page, preparatory to being admitted to the further degrees of esquire and knight. The practice of educating the higher nobility as pages at court, began to decline after the 15th c., till pages became what they are now, mere relics of feudal usages. Four pages of honour, who are personal attendants of the sovereign, form part of the state of the British court. They receive a salary of £200 a year each, and on attaining a suitable age, receive from her Majesty a commission in the Foot Guards.

PAGET, FAMILY OF. This noble family, though said to be of Norman extraction, do not trace their descent further back than the reign of Henry VII., in whose time, one William P. held the office of one of the sergeants-at-mace of the city of London. His son William, who was educated at St Paul's School, and at Cambridge, was introduced into public life by Stephen Gardiner, Bishop of Winchester, early in the reign of Henry VIII., who sent him abroad to obtain the opinions of foreign doctors as to his contemplated divorce from Catharine of Aragon. From this time forth his rise was rapid, and he was constantly employed in diplomatic missions until the death of the king, who appointed him one of his executors. He now adhered to the party of the Protector Somerset, and was raised to the peerage in 1552, as Lord Paget of Beaudesert. He shared in the power, and also in the fall, of the Protector, and was heavily fined by the Star Chamber, who also deprived him of the insignia of the Order of the Garter. His disgrace, however, was not of long continuance, and a change taking place in the councils of his opponents, he soon obtained his pardon. On the accession of Queen Mary, he was sworn a member of the privy council, and obtained several large grants of lands. He retired from public life on the accession of Elizabeth, who regarded him with much favour, though he was a strict Roman Catholic. The representative of the family adhered to the cause of Mary Queen of Scots, and suffered, in consequence, the confiscation of his property. The fifth Lord P. so far departed from the traditionary policy of the family as to accept from the parliament the lord-lieutenancy of Buckinghamshire; but he returned to his allegiance shortly afterwards, and held the command of a regiment under the royal standard at the battle of Edgehill. His grandson was advanced to the earldom of Uxbridge, but this title becoming extinct, the representation of the family devolved on a female, who carried the barony of Paget by marriage into the house of Bayly. The son of this marriage, however, having assumed the name of Paget, obtained a renewal of the earldom of Uxbridge, and the second earl, for his gallantry at Waterloo, was advanced to the marquissate of Anglesey. Of late years, the P. family have usually held three or four seats in every parliament, and they have constantly supported the liberal party.

PAGING-MACHINE. Several machines have been made for paging books and numbering bank-notes, cheques, railway-tickets, and other similar papers. The great object of these machines is to prevent the chance of error or fraud by making it impossible that a page, cheque, &c. can be abstracted or lost without detection. Messrs

Waterlow and Sons of London perfected an ingenious machine, by which pages of books, such as ledgers and other commercial books, and bank-notes, &c., are numbered in regular succession. The numbers are engraved on metal rowels, usually of steel or brass. A series of these rowels are so arranged, that when the machine is worked, the numbers must be impressed on the paper in regular succession from 1 to 99,999; and it is impossible to produce a duplicate number until the whole series has been printed. The instrument is made to supply ink to the types, so that it may be locked in such a manner as to admit of being worked without the chance of its being tampered with.

An extremely ingenious modification of this machine has been perfected by M. Auguste Trouillet of Paris, under the name of 'Numérateur Mécanique,' which is not only more simple, but admits of wider application; for it not only pages books and numbers notes, tickets, &c., but can also be used for numbering bales and other packages of merchandise. The instrument has six rowels, on each of which is a set of engraved numbers, so arranged, that their revolutions produce in regular succession the required numbers, by the action of a lever which moves horizontally, and supplies the type with ink as it moves backwards and forwards.

PA'GO, an island belonging to the Austrian crownland of Dalmatia, separated from Croatia by the Morlacca Canal, a channel from two to three miles in width. It is long and narrow, runs parallel to the Croatian coast, and has an area of 108 square miles. Pop. 6150, who are most industrious, and support themselves by vine-culture, the manufacture of salt and fishing.

PAGODA (according to some, a corruption of the Sanscrit word *bhāgavata*, from *bhagavat*, sacred; but according to others, a corruption of *put-gada*, from the Persian *put*, idol, and *gada*, house) is the name of certain Hindu temples, which are amongst the most remarkable monuments of Hindu architecture. Though the word itself designates but the temple where the deity—especially Siva, and his consort Durgā or Pārvatī—was worshipped, a pagoda is in reality an aggregate of various monuments, which, in their totality, constitute the holy place sacred to the god. Sanctuaries, porches, colonnades, gateways, walls, tanks, &c., are generally combined for this purpose, according to a plan, which is more or less uniform. Several series of walls form an enclosure; between them are alleys, habitations for the priests, &c., and the interior is occupied by the temple itself, with buildings for the pilgrims, tanks, porticos, and open colonnades. The walls have, at their openings, *gopuras*, or large pyramidal gateways, higher than themselves, and so constructed that the gopura of the outer wall is always higher than that of the succeeding inner wall, the pagoda itself being smaller than the smallest gopura. The extent of the enclosing walls is generally considerable; in most instances, they consist of hewn stones of colossal dimensions, placed upon one another without mortar or cement, but with such admirable accuracy, that their joints are scarcely visible. The gateways are pyramidal buildings of the most elaborate workmanship; they consist of several, sometimes as many as fifteen stories. The pagodas themselves, too, are of a pyramidal shape, various layers of stones having been piled upon one another in successive recession; in some pagodas, however, the pyramidal form begins only with the higher stories, the broad basis extending to about a third of the height of the whole building. The sides of the different terraces are vertical; but the transition from one to the

other is effected by a vault surmounted by a series of small cupolas, which hide the vault itself. A single cupola, hewn out of the stone, and surmounted by a globe, generally crowns the whole structure; but sometimes the latter also ends in fantastical spires of a fanlike shape or concave roofs. The pagodas are covered all over with the richest ornamentation. The pilasters and columns, which take a prominent rank in the ornamental portion of these temples, shew the greatest variety of forms; some pagodas are also overlaid with strips of copper, having the appearance of gold. The most celebrated pagodas on the mainland of India are those of Mathura, Trichinopoli, Chalambron, Konjeveram, Jaggernaut, and Deogur, near Ellora.—That of Mathura consists of four stories, and is about 63 feet high; its base comprises about 40 square feet. Its first story is made of hewn stones, copper, and covered with gilt; the others of brick. A great number of figures, especially representing deities, tigers, and elephants, cover the building.—The pagoda of Tanjore is the most beautiful monument of this kind in the south of India; its height is 200 feet, and the width of its basis is equal to two-thirds of its height.—The pagoda of Trichinopoli is erected on a hill, elevated about 300 feet over the plain; it differs in style from other pagodas dedicated to Brahminical worship, and exhibits great similarity with the Buddhistic monuments of Tibet.—The great pagoda of Chalambron, in Tanjore, is one of the most celebrated and one of the most sacred of India. It is dedicated to S'iva and Párvatí, and filled with representations belonging to the mythical history of these gods. The buildings of which this pagoda is composed cover an oblong square, 360 feet long, and 210 feet wide.—At Konjeveram, there are two pagodas—the one dedicated to S'iva, and the other to Párvatí.—The pagodas of Jaggernaut, on the north end of the coast of Coromandel, are three; they are erected likewise in honour of S'iva, and are surrounded by a wall of black stones—whence they are called by Europeans the Black Pagodas—measuring 1122 feet in length, 696 feet in width, and 24 feet in height. The height of the principal of these three pagodas is said to be 344 feet; according to some, however, it does not exceed 120—123 feet.—The pagoda of Deogur, near Ellora, consists also of three pagodas, sacred to S'iva; they have no sculptures, however, except a trident, the weapon of S'iva, which is visible on the top of one of these temples.—The monuments of Mavalipura, on the coast of Coromandel, are generally called the Seven Pagodas; but as these monuments—which are rather a whole city, than merely temples—are buildings cut out of the living rock, they belong more properly to the rock-cut monuments of India, than to the special class of Indian architecture comprised under the term pagoda.

Porcelain Tower of Nanking.

buildings, however, differ materially from the Hindu pagodas, not only so far as their style and exterior appearance are concerned, but inasmuch

as they are buildings intended for other than religious purposes. The Chinese call them *Ta*, and they are generally erected in commemoration of a celebrated personage, or some remarkable event; and for this reason, too, on some elevated spot, where they may be conspicuous, and add to the charms of the scenery. Some of these buildings have a height of 160 feet; the finest known specimen of them is the famous Porcelain Tower of Nanking (q. v.). The application of the name pagoda to a Chinese temple should be discountenanced, for, as a rule, a Chinese temple is an insignificant building, seldom more than two stories high, and built of wood; the exceptions are rare, and where they occur, as at Peking, such temples, however magnificent, have no architectural affinity with a Hindu pagoda.

PAGURUS AND PAGURIDÆ. See HERMIT CRAB.

PAHLANPUR, a town of India, capital of the state of the same name, 260 miles east-south-east of Hyderabad. It is a walled town, is the seat of extensive trade and of several manufactures. Pop. 20,000. The state of which P. is capital is within the province of Guzerat, Bombay; it has an area of 2400 square miles, and a pop. of 230,000. It has a revenue of £40,000, pays an annual tribute of £5000 to the Guicowar, and £600 per annum for a British political agent. The ruling family is Moslem, the people mainly Hindus. The products are wheat, rice, sugar-cane, and cotton. In the south and east, three crops are obtained in the year.—The *P. agency* comprises P. and ten other states; with an area of 8000 square miles, and a pop. (1881) of 576,478. Of the eleven states, four (including P.) are Mohammedan; the others are Hindu, and five of the ruling families are Rajput.

PAILA is, according to the Purán's (q. v.), one of the disciples of Vyása (q. v.), the reputed arranger of the Vedas (q. v.); he was taught by the latter the R'igveda, and, on his part, communicated this knowledge to Bâshkali and Indrapramati. This tradition, therefore, implies that P. was one of the earliest compilers of the R'igveda.

PAIN is an undefinable sensation, of the nature of which all persons are conscious. It resides exclusively in the nervous system, but may originate from various sources. Irritation, or excessive excitement of the nervous system, may produce it; it frequently precedes and accompanies inflammation; while it sometimes occurs in, and seems to be favoured by, a state of positive depression, as is seen in the intense pain which is often experienced in a limb benumbed with cold, in the pain which not unfrequently accompanies palsy, and in the well-known fact, that neuralgia is a common result of general debility. Hence, pain must on no account be regarded as a certain indication of inflammation, although it rarely happens that pain is not felt at some period or other in inflammatory diseases. Moreover, the pain that belongs to inflammation, differs very much, according to the organ or tissue affected; the pain, for example, in inflammation of the lungs, differs altogether in character from that which occurs in inflammation of the bowels, and both these pains from that occurring in inflammation of the kidneys.

Pain differs not only in its character, which may be dull, sharp, aching, tearing, gnawing, stabbing, &c., but in its mode of occurrence; for example, it may be flying or persistent, intermittent, remittent, or continued. It is not always that the pain is felt in the spot where the cause of it exists. Thus, inflammation of the liver or diaphragm may cause pain in the right shoulder, the irritation

caused by stone in the bladder produces pain at the outlet of the urinary passage; disease of the hip-joint occasions pain in the knee, disease of the heart is often accompanied with pain in the left arm, and irritation of the stomach often gives rise to headache. Pain is differently felt by persons of different constitutions and temperaments, some persons being little sensitive to painful impressions of any kind, while others suffer greatly from slight causes. There even seem to be national differences in this respect; and before the introduction of chloroform, it was a matter of common observation that Irishmen were always more troublesome subjects for surgical operations than either Englishmen or Scotchmen; and the negro is probably less sensitive to pain than any of the white races.

Although in most cases we are to regard pain merely as a symptom to be removed only by means which remove the lesion which occasions it, there are cases in which, although it is only a symptom, it constitutes a chief element of disease, and one against which remedies must be specially directed. As examples of these cases, may be mentioned neuralgia, gastralgia, colic, dysmenorrhœa, and perforation of the intestines; and in a less degree, the stitch of pleurisy, which, if not relieved, impedes the respiration, and the pain of tenesmus, which often causes such efforts to empty the lower bowel, as seriously to disturb the functions of the intestine, and to exhaust the strength.

For the methods of relieving pain, the reader is referred to the articles on the different diseases in which it specially occurs (as COLIC, NEURALGIA, PLEURISY, &c.), and to those on CHLOROFORM, ETHER, INDIAN HEMP, MORPHIA, NARCOTICS, OPIUM, &c.

PAINE, THOMAS, an author famous for his connection with the American and French revolutions, and for his advocacy of infidel opinions, was born 29th January 1737, at Thetford, in the county of Norfolk in England. He was trained to the business of his father, who was a staymaker, but afterwards obtained a situation in the Customs, and the management of a tobacco-manufactory. His income, however, was small, and he fell into debt, and was dismissed in 1774, upon which he went to America, was favourably received by a bookseller in Philadelphia, and in 1776 published a pamphlet entitled *Common Sense*, written in a popular style, in which he maintained the cause of the colonies against the mother-country. The success and influence of this publication were extraordinary, and it won him the friendship of Washington, Franklin, and other distinguished American leaders. He was rewarded by Congress with the appointment of Secretary to the Committee of Foreign Affairs, visited France in the summer of 1787, where he made the acquaintance of Buffon, Malesherbes, La Rochefoucauld, and other eminent men; and in the autumn following, went to England, where, in 1791, he published *The Rights of Man*, the most famous of all the replies to Burke's *Reflections upon the French Revolution*. The work has gone through innumerable editions, and has been translated into almost all the languages of Europe. His defence of the principles of the French Revolution against the magnificent assault of Burke and the outcry of the English aristocracy is vigorous, and by no means unsuccessful. But the value or at least the popularity of the work has been injured by its advocacy of extreme liberal opinions. His assaults on the British constitution exposed him to a government prosecution, and he fled to France, where he was admitted to citizenship; and in 1792, the department of Pas-de-Calais elected him a deputy to the National Convention, where he voted with the Girondists. At the trial of Louis XVI., says Madame de Staël, 'Thomas Paine alone

proposed what would have done honour to France if it had been accepted—the offer to the king of an asylum in America;' by which he offended the Mountain party; and in 1793, Robespierre caused him to be ejected from the Convention, on the ground of his being a foreigner, and thrown into prison. During his imprisonment, he wrote *The Age of Reason*, against Atheism, and against Christianity, and in favour of Deism. After an imprisonment of fourteen months, he was released, on the intercession of the American government, and restored to his seat in the Convention. He was chosen by Napoleon to introduce a popular form of government into Britain, after he should have invaded and conquered the island. But as Napoleon did not carry out his design, P. was deprived of an opportunity of playing the part of legislator for his conquered countrymen. He then retired into private life, and occupied himself with the study of finance. In 1802, he returned to the United States, and died there 8th June 1809. The most complete edition of his works is that by J. P. Mendum (Boet. 1856); the most noted of his numerous biographers is William Cobbett (1796).

PAINS AND PENALTIES. When a person has committed some crime of peculiar enormity, and for which no adequate punishment is provided by the ordinary law, the mode of proceeding is by introducing a bill of pains and penalties, the object of which, therefore, is to inflict a punishment of an extraordinary and anomalous kind. These bills are now seldom resorted to, and the last instance of an attempt to revive such a form of punishment was by the ministers of George IV. against Queen Caroline, an attempt which was signally defeated. When a bill of this kind is resolved upon, it is introduced, and passes through all the stages like any other bill in parliament, except that the party proceeded against is allowed to defend himself or herself by counsel and witnesses. The proceeding is substantially an indictment, though in form a bill.

PAINTER, in naval matters, is the rope by which a boat is fastened to a ship or pier.

PAINTERS' CREAM, a composition used by artists to cover oil-paintings in progress, when they leave off their work; it prevents drying, and the consequent shewing of lines where new work is begun. It consists of six parts of fine nut oil, and one part of gum-mastic. The mastic is dissolved in the oil, and then is added a quarter part of acetate, or sugar of lead, finely triturated with a few drops of the oil. When well incorporated with the dissolved mastic, water must be added, and thoroughly mixed, until the whole has the consistency of cream. It is applied with a soft brush, and can easily be removed with water and a sponge.

PAINTING, the art of representing objects to the eye on a flat surface by means of lines and colour, with a view to convey ideas and awaken emotions. See ART. As one of the fine arts, painting occupies a prominent place; some claim for it the first place, as combining the chief elements—namely, form, light and shade, and colour. As compared, however, with music and poetry, it lacks the important element of movement, the representation being confined, in a great measure, to one aspect and one instant of time. In its ruder and more elementary forms, in which the primary design was to communicate ideas, painting is perhaps the oldest of the arts, older, at all events, than writing (see ALPHABET, HIEROGLYPHICS); and, as a vehicle of knowledge, it possesses this advantage over writing—that no description, however minute, can convey so

accurate and distinct an idea of an object as a pictorial representation, much less make so vivid an impression. Besides this, it is not limited, as writing is, by differences of language, but speaks alike to all nations and all ages.

The great antiquity of painting is proved by remains discovered in Egypt, and by reference to it in ancient writings. It has been ascertained that as early as the 19th c. B.C., the walls and temples of Thebes were decorated by painting and sculpture. Ezekiel, who prophesied about 598 years B.C., refers to paintings in Jerusalem after the manner of the Babylonians and Chaldeans. Though no specimens have come down to us, it is evident that paintings of the highest excellence were executed in Greece. This is proved by what is recorded of them, for the subjects of many of those mentioned required the putting forth in a high degree of all the qualities requisite for the production of the greatest historical works, such as form, grouping, expression, foreshortening. From the immense sums given for paintings, the care with which they were preserved in temples and other public buildings, and from the fact of the high state of sculpture at contemporary periods, as proved by well-known works now extant, it may be deduced that painting, which, like sculpture, is based on design or drawing, must have occupied an equally high position. Even the imperfect specimens of painting discovered in Pompeii, where the style and influence of Greek art may be traced to some extent, lead to conclusions highly favourable to the high position of painting in classic times. The chief schools of painting in Greece were those of Sicily, Corinth, Athens, and Rhodes. The first great artist of whose works there is any authentic description, and from details of which an idea may be formed of his attainments, is Polygnotus of Thasos (flor. 420 B.C.), who painted, among other works, those in the *Pœcile*, a celebrated portico at Athens, and the *Leœche*, or public hall at Delphi.

The works of Apollodorus of Athens (flor. 408 B.C.) are described and highly praised by Pliny. Zeuxis, the pupil of Apollodorus, Eupompus, Androcles, Parrhasius (q.v.) the Ephesian, and Timanthes of Sicily, prosecuted painting with distinguished success, and by them it was carried down to the time of Philip the father of Alexander. Of the same period was Pamphilus, celebrated not only for his works, but as the master of the artist universally acknowledged as the greatest of the ancient painters, Apelles (q.v.), who was born probably at Colophon, and flourished in the latter half of the 4th c. B.C. He was highly esteemed by Alexander the Great, and executed many important works for that monarch. Protogenes of Rhodes was a contemporary, and may be styled the rival of Apelles, who greatly admired his works. His picture of *Ialysus* the hunter and the nymph *Rhodos* was preserved for many years in the Temple of Peace at Rome. Art in Greece had now reached its highest point; its course afterwards was downwards.

In Italy, art was followed at a very early period by the Etruscans, and, according to Pliny, painting, as well as sculpture, was successfully practised in Ardea and Lanuvium, cities of Latium, perhaps more ancient than Rome. The finest specimens of Etruscan art, however—as the paintings on tombs, and the remains of armour and fœtles were ornamented with figures, evince unmistakably the influence of, or rather are identical with Greek art. According to Pliny, it was introduced from Corinth about 650 B.C. No great national school of painting ever flourished in Rome, for though the names of Romans who were painters are cited, the principal

works of art that adorned the temples and palaces of Rome were obtained from Greece, and it is probable that many of the paintings executed there were by Greek artists. When the seat of empire was transferred to the East, such art as then remained was carried with it, and in a new phase was afterwards recognised as Byzantine art—a conventional style, in which certain typical forms were adopted and continually repeated. This mode has been preserved, and is practised in church-painting in Russia at this present time.

Much discussion has arisen in modern times as to the supposed technical modes or processes of painting employed by the ancients. It seems established that painting in fresco was much practised; but many of the most valuable pictures we read of were removable, and there are accounts of some carried from Greece to Rome. 'The Greeks preferred movable pictures, which could be taken away in case of fire' (*Wilkinson on Egyptian and Greek Paintings*), and Pliny says Apelles never painted on walls; besides fresco paintings on walls, therefore, there can be no doubt that the ancients painted on boards; indeed, the name *Tabula* or *Tabula picta* proves this, and it seems to be now generally acknowledged that these were executed in tempera—that is, with size, and probably fixed or protected by some kind of varnish, in the preparation of which oil was used; or in encaustic, a process in which wax was employed to fix and give brilliancy and depth to the colours, heat being applied in working with it.

Painting was revived in Europe in the 13th c.; previous to that period, Byzantine artists chiefly were employed. On the conquest of Constantinople by the Latins in 1204, the Byzantine school was broken up, and many Greek artists were transplanted to Italy, where art was now destined to flourish, so the works of the Italians who profited by their instructions, were necessarily, at the commencement, composed in the Byzantine style. The first Italian whose name is associated with the revival of Italian art is Guido di Siena; a work by him, a large Madonna, inscribed with his name and the date 1221, is still preserved in that city. The next is Giotto da Pisa (1236). But Giovanni Cimabue (q.v.), (1240—1300), is commonly styled the founder of the Italian school. Several works of considerable importance are ascribed to him; and though he followed the Byzantine arrangement, he ventured occasionally out of the path, introduced the study of nature in his drawing, and imparted a greater degree of softness to his painting than the Byzantine artists. The influence of Byzantine art was not confined to Italy; it operated in Germany, Bohemia, and France; but there also art began to assume a national character early in the 13th c., and paintings are still preserved at Cologne, dated 1224. The Italian school of painting, or that style in which so many of the highest qualities of art have been so successfully carried out, received its chief impetus from Giotto (q.v.), the son of Bordonone, born in 1276 at Vespignano, near Florence, where he died in 1336. It is said that he was originally a shepherd-boy, and being discovered by Cimabue drawing a sheep on a slate, was instructed by him in painting. His style is distinguished from that of earlier painters by the introduction of natural incidents and impressions, by greater richness and variety of composition, by the dramatic interest of his groups, and by total disregard of the typical forms and conventional style of his predecessors. His influence was not confined to Florence, but extended over the whole of Italy; and works by this artist may be traced from Padua to Naples. Giotto followed Pope Clement V.

to Avignon, and is said to have executed many important pictures there, and in other cities in France. The most celebrated of his frescoes now extant are those at Assisi; some noted works by him in that class also remain at Padua, Florence, and Naples. Most of the small easel-pictures ascribed to him are of doubtful authenticity, but some preserved in the gallery at Florence are acknowledged to be genuine. His high powers as a sculptor and architect are also exemplified by works in that city. Giotto had numerous scholars and imitators, and several of these have left works which shew that while they profited by his instruction or example, they were also gifted with original talent. Among these may be noticed Taddeo Gaddi, the favourite pupil of Giotto (born 1300, living in 1352); Simone Memmi (1284—1344); and Andrea Orcagna (1329—1389), one of the artists employed in the decoration of the celebrated Campo Santo at Pisa. Painting in Italy continued to be impressed with the feeling and style of Giotto for upwards of a hundred years; but early in the fifteenth century, the frescoes executed by Masaccio (1401—1443) in the Brancacci Chapel in the Carmelite Church at Florence, clearly prove that it had entered on a new phase, and had come forth strengthened by an important element in which it formerly was deficient, viz, correct delineation of form, guided by the study of nature. These celebrated frescoes, twelve in number, were at one time all ascribed to Masaccio; but it seems now to be acknowledged by judges of art that two of these are by Masolino da Panicale (1378—1415), the master of Masaccio; and three, or probably four, and a small portion of one, by Filippino Lippi (1460—1505). The frescoes by Masaccio, however, are superior to those by Masolino and Lippi, and, indeed, for many of the highest qualities in art, have, as compositions, only been surpassed by Raphael in his celebrated cartoons. In about a century from Masaccio's time, painting in Italy attained its highest development; but before referring to those artists who are acknowledged as having carried painting to the highest elevation it has attained since the period of the middle ages, it is right to note the names of some of the painters who aided in raising it to that position. The works of Fra Giovanni da Fiesole (1387—1455) are highly valued and esteemed by many critics as the purest in point of style and feeling, and so the best fitted for devotional purposes. Confining his efforts to simple and graceful action, and sweet and tender expression, he adhered to the traditional types, and ventured on none of the bold innovations which were introduced in his time, and carried so far by Masaccio. His example, as regards feeling and expression, influenced many succeeding artists, particularly Pietro Perugino, the master of Raphael (1446—1524), and Francesco Francia of Bologna (1450 or 1453—1517), by both of whom these qualities, united to greatly improved technical power, were brought to high excellence. Giovanni Bellini, the founder of the early Venetian school (1422—1512), has left many admirable works; he had numerous scholars, among them Titian and Giorgione. Domenico Corradi or Ghirlandajo, under whom Michael Angelo studied, successfully followed out that direction given to art by Masaccio, which involved individuality of character and expression in the figures. Andrea Mantegna, of the school of Padua (1430—1506), along with strong expression, gave an impetus to form, modelled on Greek or classic art. Luca Signorelli of Cortona (about 1440—1521), successfully exemplified powerful action and bold foreshortening, particularly in his frescoes at Orvieto, which, with his other works, are supposed to have strongly influenced

the style of Michael Angelo. Antonello da Messina (1447—1496) is said to have been a pupil of Jan Van Eyck, who imparted to him his secret in the preparation and use of oil-colours, the knowledge of which he spread among the Venetians. The above statement, however, as to the exact period at which oil-painting was first introduced, is one attended with much doubt. Painting with colours mixed in oil is mentioned by Italian writers before the period of Van Eyck; painting in tempera, or size, was continued in Italy, particularly in the Florentine and Roman schools, to the time of Raphael; and the transition from the one method to the other has been so gradual, that many judges of art have expressed inability to determine whether the pictures of Perugino, Francia, and Raphael are in oil or tempera, or in both. The practice of painting on canvas, in place of wooden boards or panels, was introduced and carried on for a considerable time in Venice before it was adopted in other parts of Italy, and canvas is the material best suited for pictures in oil-colours when they are not of small dimensions; so, on the whole, the conclusion seems to be, that though oil-painting was not unknown in Florence and the south of Italy, painting in tempera was longer practised there than in Venice. At the time when the painters above referred to flourished, there were many able artists in Germany, whose works are deservedly very highly prized. Among these, Jan Van Eyck (q. v.), (about 1390—1441), deserves special notice. To him is generally given the credit of being the first painter who used oil in place of size in his colours. His works are remarkable for brilliant and transparent colouring and high finish. He had numerous scholars; among these, Justus of Ghent (flor. 1451), Hugo Vander Goes (died 1480)—supposed to be the painter of the celebrated wings of an altar-piece, now at Holyrood Palace, containing portraits of James III. and his queen—Roger of Bruges (1365—1418), Hans Hemling or Memling (died 1489), the best scholar of the Van Eyck school; Quintin Matsys (1450—1529), Jan Van Mabuse (1470—1532), Albert Dürer (q. v.), (1471—1528), Lucas Van Leyden (q. v.), (1494—1533). The career of the two last-named extended to the best period of art, and for many high qualities their works strongly compete with those of the ablest of the Italians; while portraits by Hans Holbein (q. v.), (1497—1554), and Antonio More (1512—1588) rank with those of any school or period. The leading qualities in German art are invention, individuality of character, clearness of colouring, and high finish; but they are inferior to the Italians in embodying beauty; their representation of the nude is angular in form and deficient in the elegance and grace attained by the painters of Italy; and in their draperies they do not attain the simplicity and grandeur so remarkable in the works of their southern competitors.

Anything like an account of the artists by whom painting was carried to its highest pitch, of sufficient comprehensiveness to exhibit their peculiar æsthetic qualities, cannot be attempted in so short a notice as this; but that deficiency is in some degree supplied by, and reference is made to, the biographical notices of distinguished painters given in this work under their names. Keeping this reference in view, therefore, the next step is to note the relative positions generally assigned to the most distinguished painters of that period, with reference to the estimation in which their works are now held. Leonardo da Vinci (q. v.), (1452—1519), Michael Angelo Buonarrotti (1474—1563), and Raphael or Raffaello Sanzio of Urbino (1483—1520), are universally acknowledged as the three greatest among the Italian artists; but two other

names may be added as worthy to be put in an equally high place—those of Titian (q. v.), (1477—1576), and Antonio Allegri, surnamed Correggio (q. v.), (1494—1534). These five painters exhibit in their works, some of them the whole, others the greater portion of the various elements—which in the earlier periods of art had existed apart, and composed distinct styles—united, and more highly developed; while each of them has taken up one of these elements, and carried it not only further than his predecessors had done, but further than it was by his contemporaries, or by any subsequent artist. Thus we see in Leonardo's celebrated picture of the 'Last Supper,' that though he has adopted the traditional style of composition handed down from Giotto's time, and carried out the religious feeling and dignified expression aimed at by the older masters, the whole is deepened and elevated by the manner in which it is worked out—namely, by a mind and hand possessing mastery over all the elements that are combined in the production of the highest works of art. Michael Angelo was a proficient in all the qualities that constitute a painter, but he carried several of them—viz, grandeur of design, anatomical knowledge, and power of drawing—far beyond all other artists of his own or of later times. Titian and Correggio, again, with great power over every art-element, have each carried one quality further than all other artists—the former, colour; the latter, light and shade. Raphael is generally allowed the first place among painters, for, though each of the four artists just referred to carried one, or perhaps two, of the qualities of painting further than he did, he excelled them in every other element but the one for which each was particularly distinguished, and in several of the highest qualities of art he attained to greater excellence than any other artist; the expression of dignity of movement by broad masses and grand lines aimed at in the works of Masaccio, is successfully realised in the cartoons at Hampton Court; and the pictures in which Perugino and Francia so earnestly and successfully embodied female beauty, maternal affection, and infantine purity, are as much inferior to pictures of similar subjects by Raphael as they are above those executed during the decadence of Italian art. Besides the five leading masters just referred to, there were many other Italian artists of great talent, who may be ranged in three classes: 1, the contemporaries of those artists; 2, those influenced by their style; 3, their scholars. Among their contemporaries, the works of Fra Bartolommeo (1469—1517) and Andrea Vannucci, called Andrea del Sarto (1488—1530), both Florentines, deservedly rank very high. Giorgio Barbarelli, called Giorgione (1478—1511), was, under Bellini, a fellow-pupil of, and is generally styled the rival of Titian; and his works, which are of great excellence, prove that he was worthy of that name. In class 2, Correggio himself may rank as being influenced by Leonardo's style, but the great prominence of his other qualities makes his style original and independent. On Bernardino Luini (about 1460, living in 1530), Leonardo's influence is direct; and as he was an able painter, his pictures are very valuable for embodying many of those qualities in art which Leonardo had so much improved. Sebastiano del Piombo, a Venetian (1485—1547), studied under Giovanni Bellini and Giorgione; and after settling in Rome, became intimate with Michael Angelo, who employed him to paint some of his designs, with a view of benefiting by his admirable colouring. His pictures are greatly esteemed, as uniting rich colour to grandeur of design. Class 3. All the five leading artists above referred to had pupils or scholars, particu-

larly such of them as, like Raphael, were much engaged in extensive works in fresco, in the execution of which assistants are generally employed. A complete list of these, however, would occupy too much space here. Among the scholars of Michael Angelo, Daniele da Volterra (1509—1566) was the best; and among Raphael's scholars, the first place is generally accorded to Giulio Pippi or Romano (q. v.), (1492—1546). After the first quarter of the 16th c., painting in Italy, except in the Venetian school, shewed symptoms of rapid decline; that school, however, continued its vitality longer than any other in Italy, having flourished with all the life of originality during the whole 16th century. This is attested by the productions of many able Venetian painters; but among those, the works of Jacopo Robusti, or Tintoretto (q. v.), (1512—1594), and Paolo Cagliari (q. v.) or Veronese (1528—1588), are by far the most important. The pictures of the former exhibit great vigour in composition, and much richness of colour—the former quality evincing the influence of Michael Angelo; the latter, that of Titian. Veronese ranks before even Tintoretto: his compositions are animated and full, and as a colourist he is a powerful rival to Titian, not aiming at the rich glow of that master's tints, but excelling every artist in producing the brilliancy and sparkling effect of mid-daylight on figures gorgeously attired, and seen against backgrounds enriched with landscape and architecture. The other great schools of Italy, however, as already said, had less vitality than the Venetian, and shewed symptoms of decay at the end of the first quarter of the 16th century. Raphael left numerous scholars and assistants; many of these, after his death in 1520, quitted Rome. The pillage of that city by the French under Bourbon in 1527 had also the effect of dispersing them, and this naturally led to the style of Raphael, so far as they could acquire it, being transplanted into other parts of Italy; but Raphael's style was founded on his own peculiar feeling for the beautiful, and on his own peculiar grace; and all that his scholars had acquired or could convey was a mere imitation of his external forms, without the spirit and pure feeling of which these forms are the expression. The imitation of Michael Angelo became the great object with the Florentines; but his scholars and imitators being unable to comprehend his powerful spirit, and not possessing his technical powers and theoretical knowledge, their pictures are merely exaggerated compositions of academic figures. Nor were Correggio's scholars more successful in following his walk, for they exaggerated the peculiarities of his style, which in their hands became affected and insipid. Leonardo's scholars repeated his distinguishing qualities, modified by their own individual peculiarities. (Ruskin made it his work to teach 'the supremacy of five great painters, Turner, Tintoret, Luini, Botticelli, and Carpaccio, despised till he spoke of them.')

The German painters who succeeded Dürer, Van Leyden, and the other celebrated artists of their period, before referred to, endeavoured to improve their national style by the study of Italian art, at first attempting to combine the two styles, and afterwards, to the close of the 16th c., devoting themselves exclusively to the study or imitation of the Italian painters. The works of these artists, the worst productions of any school, form a connecting link between those of the famous old German masters and the vigorous, varied, and attractive works of the painters of the Netherlands in the 17th century.

Towards the end of the 16th, and during the first half of the 17th c., a revival of art in Italy was attempted. This was sought for in two ways by two classes of artists; the larger body were known

by the name of Eclectics, from their having endeavoured to select and unite the best qualities of each of the great masters, combined with the study of nature; the other class were distinguished by the name of Naturalisti, and they aimed at forming an independent style, distinct from that of the earlier masters, based on the indiscriminate imitation of common life, treated in a bold and lively manner. In their development, both classes exercised an influence on each other, particularly the Naturalisti on the Eclectics. Eclectic schools arose in various parts of Italy, but the most celebrated was that at Bologna, founded by Lodovico Carracci (q. v.), (1555—1619), assisted by his two nephews, Agostino Carracci (1558—1602), and Annibale Carracci (1560—1609) the most eminent of the three. Many painters of mark were reared in this school; among those, Domenico Zampieri, called Domenichino (q. v.), (1581—1641), and Guido Reni (q. v.), (1575—1642), were by far the most eminent. The art of the Eclectics has been greatly overrated. Till recently, the leaders of that school were always placed on an equality with the best masters of the early part of the 16th c., and far above any of the painters of the 15th century. These notions have recently undergone a complete change; it is now acknowledged that the attempt of the Eclectics to combine the excellences of various great masters, involves misapprehension with regard to the conception and practice of art, for the greatness of the earlier masters was brought out in their individual and peculiar qualities, the uniting of which implies a contradiction. Michael Angelo Amerighi da Caravaggio (q. v.), (1569—1609) was the founder of the Naturalistic school; he resided principally at Rome, but at a later period went to Naples, Malta, and Sicily. The Naturalisti were in their greatest strength at Naples, where they perseveringly opposed the followers of the Carracci, their leader being Giuseppe Ribera (q. v.), a Spaniard, hence called Spagnoletto (1593—1656). With much of the force of Caravaggio, he united more delicacy and greater vivacity of colour. The historical or Scriptural subjects of Salvator Rosa (q. v.), (1615—1673) are in the style of the school of the Naturalisti; but on account of his *genre* pieces and landscapes, Salvator is entitled to occupy the place of the originator of a style noted for certain qualities of poetic feeling. The influence of the school of the Naturalisti had more important results than that of the Eclectics, for it affected to some extent the leading masters of the Spanish school. At Rome, contemporaneously with Domenichino, Guido, and other leading masters of the schools of the Eclectics and Naturalisti, the three following artists elevated landscape-painting to a high position—Nicholas Poussin (q. v.), a Frenchman (1594—1665); Claude Gellée, also a native of France (1600—1682), called Claude Lorraine (q. v.); and Gaspard Duchet, named Gaspar Poussin (q. v.), born in Rome, but the son of a Frenchman (1613—1675). Among the great masters who occasionally practised landscape-painting as a distinct branch of art, the earliest were Titian and Giorgione; the Carracci (particularly Annibale) carried out their style with considerable success; the landscapes of Domenichino are esteemed, and other scholars of the Carracci turned their attention in that direction. The reputation of N. Poussin is principally based on his figure-pictures, the subjects of which were mythological and Scriptural. Into these pictures, he endeavoured, with considerable success, to infuse the classical style; but his compositions were generally arranged with a large space of landscape background, which was in many cases not the least important portion of the picture; and these, and the pictures he painted falling strictly

under the class of landscapes, are distinguished for largeness of style and poetic feeling. Claude and Gaspar directed all their efforts to landscape, and attained to high eminence in that department of art.

The earlier specimens of painting in Spain resemble in style the works of the old German painters, who seem to have disposed of many of their pictures in that country, while Spanish art of the 16th c. was modelled on that of Italy, Titian and Raphael being the masters studied; but when works of the Spanish school are spoken of, those executed in the 17th c. are always understood to be referred to, as it was then that Spanish art became entirely national in feeling and style, and that is the period in which the best works of the school were produced. The two most distinguished Spanish painters are Don Diego Velasquez (q. v.), (1599—1660), and Bartholomæ Esteban Murillo (q. v.), (1618—1682). The portraits of the former are characterised by truthful and dignified expression, great breadth and vigorous handling, and rank with the best works of that class of any school; while the Scripture subjects of the latter, which are noted for tender expression, rich colour, and powerful light and shade, may be classed with similar works by Rubens and Van Dyck. Spagnoletto, a Spanish painter, has already been referred to as a leading artist of the school of the Naturalisti at Naples. Alonso Cano (1601—1667), Francisco Zurbaran (1598—1662), and Claudio Coello (born between 1630 and 1640—1693), have a high reputation. No name of a Spanish painter of eminence occurs after the close of the 17th century.

Very soon after the period when the Eclectic and Naturalistic schools arose in Italy, a revival of art also occurred in the Netherlands. This was very different in its effects from the revival in Italy, the only results from which were academical imitation of the older masters, and coarse naturalism, either separately or combined in varied proportions; while the works of the artists of the Netherlands executed about the same period, though they do not exhibit the high qualities found in the compositions of the Italian masters of the best period, possess many new and attractive features—freedom, originality of treatment, attention to the peculiar character of individual life, and the daily intercourse of men with each other in all its variety, and the study of nature, brought out with truth and delicacy of execution. Two important schools of art were established by this movement—the Flemish and the Dutch. The Flemish school flourished in Brabant, where the Roman Catholic faith—then making strenuous efforts to oppose the Reformed religion—still retained and actively employed art in its service. The Dutch school flourished in Protestant and republican Holland, where the artist, having to trust to private encouragement, painted, for the most part, familiar subjects from everyday life; and in place of altar-pieces for churches, and large historical and allegorical pictures for palaces, produced the subjects then in demand—portraits, *genre* pictures, or works in which life and manners are depicted in various phases—landscapes with and without figures, sea-pieces, battle-pieces, compositions representing hunting, animals, game, &c. The catalogue of the names of the able artists of these two schools is long; in the Flemish school, those who stand highest are Peter Paul Rubens (q. v.), (1577—1640), Anthony Van Dyck (q. v.), (1599—1641), David Teniers (q. v.) the Younger (1610—1690), F. Snyders (1579—1657). The following are the most eminent in the long list of artists of the Dutch school: Rembrandt (q. v.), (1606—1669), Vanderhelst (1612—1670), Albert Cuyp (q. v.), (1606—1691), Terburgh (1608—1681), A. V. Ostade

(1610—1685), J. Ruysdael (q. v.), (1630 or 1636—1681), Hobbema (1629—1670), P. Potter (1625—1654), K. du Jarden (1635—1678), Jan Steen (q. v.), (1636—1689), G. Metsu (1615—1668), F. Mieris (1635—1681), W. Van de Velde (1633—1707), A. Van der Neer (1613—1684), P. Wouvermans (q. v.), (1620—1668).

Painting has been practised for a very long period in France; but there, as in Spain and in Britain, the marked preference shewn in early times by the sovereigns of the country for the works of foreign artists, their undervaluing native talent, and their directing it into a channel supplied from a foreign source, had the effect of neutralising it as the exponent of national feeling. Francis I. is acknowledged to have been a patron of art; he had a desire to possess fine works, and he liberally rewarded able artists, but his patronage was almost entirely confined to foreigners. Louis XIV. did what he could to place French art above that of every other nation; but he had no knowledge of it himself; he did not comprehend its nature and true intention, and imagined that pictures if painted by Frenchmen must necessarily be national. Nevertheless, his influence was, on the whole, highly beneficial to French national art. He always shewed himself desirous to employ native rather than foreign talent, and he encouraged and enlarged the Academy of Fine Arts, which had been founded at the commencement of his reign, under the direction of Lebrun. Although in many respects the principles and the regulations of the Academy tended rather to the perpetuation of debased Italian, than to the development of genuine French art; yet the bringing together of a body of influential French artists, was the measure most likely to foster the feeling of nationality and to lead to the foundation of a national school of art. In the 16th c., François Clouet was distinguished as a portrait-painter; and Jean Cousin as a painter, sculptor, and architect. In the 17th c., among many names, those chiefly deserving notice are Simon Vouet, the brothers Le Nain, N. Poussin, Claude Lorraine, Mignard, S. Bourdon, Le Sueur, J. Courtois (called Borgognone), and Coppel. Among these, the works of the brothers Le Nain alone possess national feeling and character, and they are held in very considerable estimation; those of the others were executed under the influence of foreign art; and excepting Claude's splendid landscapes, Poussin's learned compositions, and some of Borgognone's battle-pieces, hold a low position. The works of Anthony Watteau (1684—1721) are truly national, excellent in execution, and very highly valued. This artist may be classed as at the head of the school of the 18th c.—the period in which art in France became really national. Not only did most of the painters of his school—which lasted till the end of the century, when classic art ruled for a time—form their style upon the works of Watteau, but his influence also affected the British school, which arose soon after that of France was developed. Lancret (1690—1742) was the most successful imitator of Watteau; Fater (1696—1736) followed in the same course; Chardin (1699—1779), though influenced by him, had an original style of his own, and his works now stand high. The pictures of Boucher (1704—1770) exhibit the defects of the French school of the 18th c., unredeemed by the delicacy and grace, and high technical execution and truth of Watteau, Chardin, and Greuze (1725—1805), the last of whom sustained the character of French national art, and carried it into the 19th c., when it was re-established, after the classic school of David, founded at the Revolution, and patronised under the empire of the first Napoleon, had in its turn been

laid aside. David (q. v.), (1748—1825), the leader of this school, carried his admiration of classic art to the length of substituting the study of statues, the works by which the art of the ancients is chiefly known, for that of nature. He had numerous able pupils, several of whom, tired with this constant repetition of conventional form, recurred to nature, extended their range of subjects, and infused new vigour into the French school. Among many distinguished artists that have maintained the fame of the French School during the present century the following names may be mentioned: Géricault, Prud'hon, Leopold Robert, Delaroche (q. v.), Horace Vernet (q. v.), Ary Scheffer (q. v.), Eugène Delacroix (q. v.), and Ingres (q. v.). A number of artists, chiefly pupils of the above, now sustain the high position of French art in every department; while in that of landscape illustrative of French scenery, a branch of art never much studied in past times, great progress has been made, and the rise of this flourishing branch of French art is acknowledged by the French themselves to be due to the works of the English painter Constable, exhibited in Paris in 1824.

The English school was the latest national school that arose in Europe, for although the modern schools of Germany and Belgium are of still later date, having arisen in the present century, still they can scarcely be classed as new schools, but rather as revivals of former national schools. In England, as in France, foreign artists chiefly were in early times employed by the court and the nobles. Henry VIII. competed with Francis I. for the services of the greatest of the Italian artists, and permanently secured those of Hans Holbein, one of the most distinguished of those of Germany. Charles I. liberally patronised Rubens and Van Dyck; and if he had reigned longer, would in all probability, like Louis XIV., have founded a national school. But referring to the separate notices in this work of the foreign artists under their names respectively who were employed in this country, and to the article **MINIATURE PAINTING** for notice of several eminent native artists in that branch of art, it is only necessary here to touch on the subject of painting in this country from the time it acquired a truly national character. At the beginning of the 18th c., art in Britain was at the lowest ebb; the career of Sir Godfrey Kneller (q. v.), (1648—1725 or 1726), the last of the foreigners, was drawing to a close; Sir James Thornhill (1676—1734), an Englishman, followed out the decorative kind of art on which Verrio, Le Guerre, and others were so much employed; but after his death, that debased style finally went down. The time had now arrived for native artists, if there were any entitled to the name, to assert their independence; and accordingly, in 1734—1735, as many as from thirty to forty artists combined together in London, and instituted an academy for studying the human figure. About the same time a similar movement was going on in Edinburgh; the contract or indenture for establishing a school of art, dated 18th October 1729, and signed by seventeen artists, besides amateurs, is in the possession of the Royal Scottish Academy. The effort above referred to, of artists combining to found a Life Academy, was mainly due to William Hogarth (1697—1764), who, on this account, and from his first having developed, in a very high degree of excellence in his works, the leading characteristics of the English school, is justly entitled to be considered its founder. This combination led to these important results—it shewed the artists their strength, and enabled them, after a probation of thirty-four years, to found the Royal Academy, an institution managed by artists,

and intended to support and encourage a national school of art. The means by which the Royal Academy proposed to attain its purpose were the following: 1, by founding a school where artists may learn their profession; and 2, by instituting an exhibition where, independently of private patronage and support, artists may bring their works directly before the public. Hogarth died four years before the Royal Academy was organised; but he powerfully contributed to its establishment by his exertions in bringing the artists together in 1734, by supporting the modern exhibitions at Spring Gardens, and by ridiculing by his pencil and pen the passion of the cognoscenti of the day for crying up as superior to the modern the doubtful specimens of old art which were largely imported and disposed of at great prices in numerous salerooms established for the purpose in London. As regards technical execution, and indeed in style generally, the English artists were at first indebted to the French school, which, in the commencement of the 18th c., was in great vigour. Hogarth himself, in these respects, looked closely at the works of Watteau, engravings from which were well known in this country in his time; indeed, Watteau's pictures were so greatly admired here that he came over and spent the year 1720 painting in London. But Hogarth, though alive to the qualities in art produced by others, ranks among painters as one of the most original, for he greatly extended the dramatic element in painting, and imparted an originality and vigour to it never before attained; and his example has led to that element being one of the leading features of the English school, as is exemplified in the works of Wilkie (q. v.), Leslie (q. v.), Stuart Newton, Bonington, and others; and those of many distinguished artists of the present day. In the department of portrait-painting, many of the works of the British school rank with those of Titian, Van Dyck, and Velasquez, such, for instance, as Reynolds's portraits of Nelly O'Brien and Lady Hamilton, Gainsborough's Mrs Graham and Mrs Siddons, and some of Raeburn's heads, &c. While in that of landscape, the position of the English school is acknowledged to be very high, its influence now strongly affecting the French school—this is proved by the works of R. Wilson, Gainsborough (q. v.), and Turner (q. v.), the last of whom, for wide range of subject, and rendering of atmospheric effect, stands alone; Constable, whose powerful grasp of nature has excited the emulation of the French artists; Calcott (q. v.), Collins (q. v.), Nasmyth, J. Thomson, Muller, and others; and their successors, the artists of the day, who ably represent the English school. Animal-painting has also been elevated to a high position. And an important department, that of Water-colour Painting (q. v. in SUPP., Vol. X.), originated in England, and has there attained higher excellence than elsewhere.

Painting is cultivated with success and receives much encouragement in America, but there the features that mark a national school have not yet had time for development. From the close connection between Britain and America, the art of the latter country was naturally influenced by and became assimilated to that of the former. America may, however, justly take credit for having contributed in no small degree to strengthen the British school of art, as several very able members of the Royal Academy were Americans. Benjamin West (1738—1820) was one of the original members, and elected President of the Royal Academy in 1806. J. S. Copley (1737—1815), elected R.A. in 1799; his 'Death of Chatham,' and 'Defence of St Heliers, Jersey, against the French, and Death of Major

Pierson at the moment of Victory,' are excellent works, and as such were conserved in the National Gallery, London. C. R. Leslie (1794—1859) was born in London of American parents; but in 1799, went to Philadelphia, where he was educated. Returning to London in 1811, he entered the schools of the Royal Academy; was elected academician in 1826, and professor of painting in 1848. G. S. Newton (1794—1835)—he was admitted a student of the Royal Academy in 1821, and elected academician in 1832. Washington Allston (1780—1843) was elected an associate in 1818; but afterwards returned to America, where he died. With the exception of the last named, the feeling evinced in the works of all these artists, influenced by study and continued residence, was essentially English; indeed few have equalled Leslie and Newton in their power of embodying the various incidents made national by English poets; and in none of their works can anything be set down as contributing in any degree to the foundation of a national American school. There is every reason to think, however, that such a school is being gradually evolved, and will soon be developed. Already something like originality of a national kind is exhibited in landscape painting, in which some American artists are endeavouring to embody scenes embracing a vast extent of country, or of extraordinary magnitude—such as those met with in the Andes, at Niagara, or exhibited by floating icebergs; and American literature, having now assumed imposing proportions, and great historical events having recently taken place, illustrations of American poetry and pictures of stirring national events will be called forth; and able American artists will doubtless be found to embody them and create a school truly national.

A general survey of painting at the present time exhibits the following aspect and arrangement: 1. A school in Germany, which arose during the present century, ostensibly a revival of the old national, but truly modelled on the early Italian school, the religious element being prominent. Its principal works are mural, of large dimension, and mostly executed in fresco, or on a kind of fresco lately invented, called silica or water-glass painting, from a vehicle of that kind being used. Invention, composition, grouping, and powerful and correct drawing, characterise the modern German works; but being of necessity executed from cartoons, they are deficient in that amount of individual expression, and natural colour and effect, that can only be attained by a direct and continued reference to the object represented. 2. A Belgian school, which arose in the present century, and is also a revival of the earlier national schools. Some of the Belgian artists lean to the manner of the very early Flemish school, others to that of which Rubens was the head. The greater portion of the Belgian works are easel-pictures, and many of them rank high for individual expression, colour, and technical execution. 3. A French school, exhibiting in active operation the various styles that have at different periods prevailed in that country, sometimes modified or adapted to the taste and feeling of the times. The works of the French school of the eighteenth century were utterly condemned by French artists at the close of that and commencement of the present century. They would tolerate nothing but what they called classic art. *L'Ecole classique*, as it was styled, was in its turn supplanted by *l'Ecole romantique*. Now, however, all styles are tolerated, even those of foreign schools—for instance, the English school of landscape—and there can be no doubt that, by the extensive range of subject, invention, drawing, and other high qualities the

French artists display in their works, they have now raised that school to a very high position. 4. A British school, which has been in existence as a national school nearly as long as that of France, undisturbed by the convulsions that affected it. Vitality in art is maintained by close reference to nature, and this has all along been the leading characteristic of the English school; while the tendency of the artists at present is, taking advantage of the aid of science, which has lately discovered photography, to study nature with still greater earnestness and care. The high claims of the British school, long denied abroad, are now fully admitted. Formerly, foreigners never classed a British school among those of Europe, but now this is invariably done. One of the most popular writers on art in France, Théophile Gautier, in his work, *Les Beaux-Arts en Europe*, divides the art of the world into four strongly defined zones—viz., Great Britain, Belgium, Germany, and France—Britain being distinguished by 'individuality,' a potent element in art; Belgium, by 'skill;' Germany, by 'ideality;' and France, by 'eclecticism,' or a selection and combination of the qualities of all other schools.

Regarding technical modes or processes of painting, reference is made to the separate notices under *Fresco*, *Encaustic*, *Miniature Painting*. The period when the method of mixing up colours with oil was introduced, and the artists to whom the invention is attributed, have been already alluded to. It is necessary, however, to enter on some details touching the mechanical processes in oil-painting, the branch of the art that occupies the most prominent position; and the practice of cleaning and restoring pictures.

The implements used by a painter in oil are charcoal, chalk, or lead pencils, for drawing the outline; hair-pencils or brushes of various sizes, made of hog's bristles or finer hair, such as sable; a knife or spatula to mix the colours, and a palette or small table of thin wood, to be held in the left hand, on which the colours and tints are placed and mixed; an easel or stand for supporting the picture is also required, and a light rod for steadying or resting the hand on. Large pictures are always executed on canvas, stretched tightly on a frame, and primed or coated with paint. Small pictures are often painted on boards or panels, generally of hard wood, such as oak or mahogany, and similarly primed or prepared; but canvas, even for small works, seems at present to be generally preferred. Panels are apt to twist, or warp, or split, and in the event of the surface of a picture chipping or breaking off from the ground, the damage can be more easily remedied, and its progress stopped, when the picture is on canvas, by re-lining. The colour of the ground of the canvas or panel has been the subject of much diversity of opinion among artists in different countries and at various periods; and it is certainly a matter of great importance, as it affects the general colour of the work, or makes it necessary for the artist to adopt a peculiar style of working. The colour of the ground used by the early masters was white, or nearly pure white. This arose from tempera or size being the medium first used in painting, and a pure white ground prepared with size was necessary for that kind of work. This practice, except as regards the Venetian school, continued till the decline of Italian art. Dull red was the universal colour adopted in the eclectic, Naturalist, and late Italian schools, and this is one of the causes of the works of these schools being characterised by blackness and heaviness; at the same time, it is certain that red grounds were also used by many of the best Venetian painters, in whose works these defects are

never found, probably from having used an impasto or body of colour sufficiently powerful to bear out on the ground. A dark ground affords a facility for working expeditiously, and that, probably, was the principal cause for its being adopted. The Dutch and Flemish painters generally used light grounds; some of them light-brown, nearly the colour of oak. Van Dyck occasionally used gray, and sometimes, when he painted in Italy, dull-red grounds. In the British school, light grounds are preferred. Some artists use smooth canvas, others prefer it rough, and avail themselves of the texture to increase the richness of the surface of their work. All these varieties in the materials are called for in consequence of the numerous styles or modes adopted by painters in oil colours. Every artist has his peculiar way of working, and in bringing out the colour or effect, or special quality in his picture, by which the feeling or idea of the subject he conceives is expressed. No two artists—imitators and copiers are not referred to—produce their tints by mixing colours in the same proportions, nor, indeed, by using the same colours; and it is difficult to lay down general rules for the execution of works, seeing that depends very much on individual feeling and appreciation. The design or drawing is first outlined on the canvas, if it is light, with charcoal, or with white chalk when it is dark, and these lines are easily dusted off or rubbed out when corrections are made. It is then put in with black chalk or a lead pencil. Not many years ago it was the practice of painters, particularly landscape-painters—Nasmyth, for instance—to rub in the design with some brown colour, such as a tint composed of burned sienna and black; but this practice is not much adopted now. Some artists make but a slight outline, and paint—or, as it is called technically rub—in the subject in a bold, rough manner, afterwards gradually finishing it up; others draw the design very carefully, and work the picture up in portions, finishing or nearly finishing one portion before commencing another. In arranging the colours, or as it is called, setting the palette, many artists use a great variety of colours, others produce rich tones with few colours; some mix up tints in various gradations, others place the colours on the palette, commencing at the outer edge with white, followed by yellows and burned sienna (a reddish brown), then reds, including lakes, such as pink, madder, next blue, and lastly black, and merely mix up the tint on the centre of the palette with their brush, as they proceed. In laying the colours on the canvas, the painter with his brush mixes or dilutes them with what is called a vehicle or medium. Here, again, the practice of artists is very varied; and this is a matter of importance, as the tone and quality of the picture, as regards texture or surface and transparency, is much affected by the medium employed, and the manner of using it. The durability of the work also depends very much on the medium and the artist's management of it. A medium composed of mastic varnish and drying or boiled linseed oil, named magilp, is that most generally used. This mixture coagulates or forms a jelly, and has the advantage, when placed on the palette, of not running off it, or mixing with the colours when the palette is not held level. Some painters prefer using raw linseed oil mixed with a dryer, such as litharge, or drying oil mixed with turpentine, or copal varnish and turpentine, or copal varnish and oil, with mastic varnish added, to make it coagulate. Other ingredients are often mixed with the medium, to give a thick consistency to the paint, such as fat or thickened nut oil, paste, &c.; and various preparations sold by artists' colourmen are much used; for instance, Roberson's medium,

and Siocatif de Harlem, a preparation imported from Paris. The mode of using the medium is of great consequence; some apply it very sparingly, others, particularly those who prefer maglip, or a medium that coagulates, employ it lavishly. By the first method, firmness and decision of touch may be exhibited, by the latter, richness and brilliancy of tone; the excess tends to produce, in the one case, a hard and dry surface, and the want of the protection that varnish mixed with the colour gives against atmospheric action; the other induces a surface having a horny appearance, and a tendency to darken, or crack, or open up.

Arresting the decay of pictures, and repairing, or, as it is styled, restoring them, after they have suffered from age or bad usage are matters which engage much attention. There can be no doubt that many paintings of vast importance have been saved by the care and skill of those who have earnestly devoted themselves to that kind of work; but picture-cleaning is now a trade followed in numerous instances by ignorant pretenders and quacks, who hold out that they possess some means by which they can freshen a picture, and restore it to the state it was in when originally executed. Generally speaking, the great extent to which this business is carried on is owing to the credulity of those who dabble in collecting old pictures, one great incentive to which being the hope of picking up, or discovering, some picture of great value concealed under the dirt and discoloration acquired in a long course of years; but, nevertheless, there can be no doubt that many proprietors of works of art who collect from far higher motives, are remarkably prone to call in the picture-cleaner when his services are anything but necessary or beneficial. The late Sir Edwin Landseer, R.A., when examined by the Select Committee of the House of Commons appointed to inquire into allegations of damage by cleaning, sustained by the pictures in the National Gallery of London (Report and Evidence ordered to be printed, 1858), stated in the following terms, his idea of this rage for picture-cleaning, or rather picture-destroying: 'The first thing, whenever a picture is sold, I think, is, that it goes to a picture-restorer, or a picture-liner, or a picture-cleaner, no matter what its condition is. It is exactly the same thing as when you buy a horse; your groom says he will be all right when he has a dose of physic through him, whether he wants it or not.' The mania for picture-cleaning is not confined to this country; it is extensively carried on with even more ruinous consequences abroad, particularly in Italy, where there is a large traffic in old, and few commissions for modern works, and where in many of the public galleries one or more picture-cleaners, for whom work must be found, are attached as permanent officers.

The process of picture-cleaning, or the removal of the old varnishes or other incrustations by which a painting may be obscured, is effected either by mechanical or chemical means. The first method is accomplished when the varnish on the surface is mastic, by rubbing with the fingers the surface of varnish when in a dry state, by which action it is brought off in a fine white powder; or by scraping or erasing the surface with sharp steel instruments when the surface of the picture is tolerably smooth. The first of these processes is the best that can be employed; but when the surface is rough or unequal, the prominent portions are apt to be over-rubbed; erasing or scraping is often practised in Italy, but rarely in this country. The chemical means consist in the application of solvents, chiefly alkali, or alcohol, to dissolve the old varnish. The danger here is, that the action of these solvents is

not always stopped with sufficient promptness and dexterity, and part of the surface of the picture is taken off; consequently it is by this latter process that most destruction is caused. For the various methods employed in picture-cleaning, the Report and Minutes of Evidence, already referred to, may be consulted, and *Lejeune's Guide*.

See *History of Painting, Ancient, Early Christian, and Mediæval*, from the German of Woltmann and Woermann, edited by Sidney Colvin (1880); *Classic Painting*, by Poynter and Head (1880); and the standard works of Vasari (Florence, 1568); Borghini (Florence, 1584); Rodolphi (Venice, 1648); Zanetti (Venice, 1771); Lanzi (1792), Bohn's edition of Roscoe's translation; Von Rumohr (Berlin, 1827); Kugler's *Hand-book of Painting, Italian Schools* (ed. by Eastlake, 1855), *German, Flemish, and Dutch Schools* (1846), *Spanish and French Schools* (1848); *History of Painting in Italy*, by Crowe and Cavalcaselle (1876); *Hand-book for Young Painters*, by C. R. Leslie, R.A. (1855); *Ruskin's Modern Painters* (1843—1860).

PAINTING (HOUSE), is one of the useful arts, combining much that is artistic with much that is absolutely necessary. The primary object of painting houses, or parts of them, either internally or externally, is to preserve them from decay—to cover the parts liable to suffer from exposure with a durable composition. That now used is made of ground white-lead mixed with linseed oil. This produces white paint, which forms the basis of all others. The various colours given to it are produced by the grinding of pigments (or *stainers*) along with the white-lead. The commonest of these are ochres (yellow and red earths), lampblack, Venetian red, umber, Prussian blue, chrome, vermilion, &c. Substances called driers are also mixed with the paint, such as spirits of turpentine, boiled oil, litharge and sugar of lead ground in oil. Paint may be laid on any material—stone, wood, iron, and plaster being the most usual in buildings. It has the effect of preserving these, by filling up the pores in them, and forming a coating on which the moisture of the atmosphere does not act. The paint is laid on in several coats or layers, each being allowed to dry before the next is applied. The usual number of coats for new wood or plaster varies from three to six. Five coats form a good and lasting protection from the weather. Plain painting is generally finished with a coat prepared with a mixture of oil of turpentine, which takes off the gloss from the paint, and leaves the surface quite *mat* or dead. This is called *flattening*. A very common form of decoration in all ages has been to imitate the veins or colours of marbles, and the *grains* or marks of growth of various woods. In modern times, these arts form a separate branch of house-painting, some men being *grainers*, others *marblers*, &c. The mode in which these imitations are produced is by forming a *grounding* of several coats of plain paint—usually four—and applying the colouring coat over this. In marbling, the colouring matter is marked and veined with *feathers*, in place of brushes; and in graining, steel combs are used. When the surface is dry, it is protected with one or more coats of copal varnish.

Besides painting, the decorator uses paper-hangings for adorning the walls of houses. These are applied to the walls with paste. Size-colouring is also used; the colouring matter in this case being mixed with strong Size (q. v.) in place of oil; but this has the disadvantage of being easily acted on by moisture. It is often used for the ceilings of common rooms, and for the walls of kitchens and servants' apartments, being much cheaper than oil-paint. In ancient times, in Greece and Rome, wax was used for mixing the colours with; but although

there are many very fine specimens of Roman paintings still preserved on the walls of the houses of Pompeii, the mode in which these decorations were applied is not now known.

PAINTS, PAINTERS' COLOURS, or PIGMENTS. These names are applied to the prepared or unprepared compositions by which wood, stone, and other materials are coated with a preservative surface of oil, mixed with an earthy matter, to give it colour and consistency; also to the materials used by artists to produce the coloured surfaces of their pictures. The art of painting, in its primitive state, consisted merely in applying such natural, mineral, and vegetable colours as were spontaneously yielded, without any vehicle to render them permanent; consequently, they had to be renewed as often as they were rubbed or washed off from the surfaces to which they were applied. The paints now in use are nearly all mixed with a liquid vehicle, and are applied in the liquid state. The mixing materials are varied according to the requirements of the work. Thus, for some kinds of decorative work, and for water-colour drawings, gum, glue, size, or other adhesive materials dissolved in water, are employed; whilst for the painting of buildings, &c., and for oil-paintings, oils of various kinds are used for mixing and thinning the colours. Thus, for painted work exposed to the weather, it is found that linseed oil boiled with the sulphates of lead (litharge) or zinc, or with acetate of lead (sugar of lead), is the best. The preparation of boiled oil is one requiring particular care, as it is desirable to have it bright and clear. Hence the proportions of the metallic salts are much varied by different manufacturers, and by some various other ingredients are added. The time of boiling, and the method of filtering, are also much varied. For indoor work, plain linseed oil and oil (spirit) of turpentine are used; if a *glossy surface* is wished, the linseed oil must be in excess; if a *dull or flattened surface*, then the quantity of turpentine, or *turps*, as it is often technically called, must be increased; and it is usual to add a small quantity of ground litharge and sugar of lead, which are prepared for this purpose, and sold under the name of *Driers*. For artists' colours, very fine linseed or nut oil is used, unboiled, and in small quantity, and turpentine is employed to dilute them. Paints for very rough purposes, such as ship-work, stone walls, &c., are often mixed with whale oil boiled with white vitriol (acetate of zinc), litharge, and vinegar, and they are diluted with common linseed oil and turpentine.

Most of the paints used for ordinary purposes are composed first of the colouring matter, then of a quantity of white-lead, with which and the oil they are worked into a paste of the shade required, and afterwards thinned down with oil and turpentine when used. The white-lead which thus forms the basis of most paints, and by itself a colour, is a carbonate and oxide of the metal, produced by exposing pieces of lead to the action of the steam of acetic acid in beds of fermenting tan. It is the principal white paint used, but is liable to discoloration from the gases contained in impure atmospheres. Other white pigments are prepared from the oxide of zinc, and the carbonate and sulphate of barytes. Pale yellow is made with chromate of strontian, orange-yellow with sulphuret of cadmium, whilst several varieties of this colour are produced by chromate of lead, sulphuret of arsenic, or king's yellow, and various native earths in which silica and alumina are combined with oxide of iron. Amongst these are Yellow Ochre, Oxford, Roman, Stone, Orange, Indian, and American Ochres. Reds are either purely mineral, or they are

lakes, i. e., organic colours precipitated on alumina bases. Of the latter, there are madder-lakes, prepared from madder-roots, and carmine-lakes, prepared from cochineal; of the former, vermilion (bisulphuret of mercury), Indian red (a native oxide of iron), Venetian red (also an oxide of iron), red lead (red oxide of lead or *minium*). A very beautiful red is used by artists called palladium red; it is formed of ammonio-perchloride of palladium. Blues consist of the artificial ultramarine, and for artists' purposes, of the real ultramarine, also the silicate of cobalt, and for water-colours, indigo and Prussian blue. Greens are either produced by mixtures of yellows and blues, or they are made directly from the phosphates, carbonates, acetates, and arsenites of copper, also from the sesquioxide of chromium and from *terre verte*, a native mineral, consisting of iron, silica, potassa, and magnesia. The last two are the best for artists. Browns are numerous, and various in their composition. Decomposed peat, burned madder, burned Prussian blue, burned terre verte, asphalt, manganese brown, catechu, umber (which is an oxide of iron with manganese), and mummy, or the asphalt mixed with other matters taken from Egyptian mummies, are amongst the best known and most used. Blacks are made of Lamp-black and Bone-black (q. v.), peroxide of manganese, and blue-black, which is made of the charcoal of burned vine twigs.

In all cases, the colouring materials of paints require to be very finely ground, and as many are very poisonous, great care is required in their preparation, and several forms of mill have been invented for the purpose. The principle upon which all are made is to secure the operator from the poisonous dust and exhalations, and to reduce the colouring material, if ground dry, to an impalpable powder, or if mixed with the oil, to a perfectly smooth paste.

PAISIELLO, GIOVANNI, an eminent musician, son of a veterinary surgeon at Taranto, was born in 1741, and received his musical education in the Conservatorio St Onofrio at Naples. Of his earlier operas produced at Naples, the most celebrated was *Dal Finto al Vero*, composed in 1777. Some of his best works, particularly *Il Barbiere di Seviglla*, were written during an eight years' residence at St Petersburg. At Vienna, he composed twelve symphonies for a large orchestra, and the opera buffa, *Il re Teodoro*. Between 1785 and 1793, he produced a number of operas for the Neapolitan theatre, and was appointed by Ferdinand IV. his *maestro di capella*. In consequence of having accepted under the revolutionary government the office of national director of music, he was suspended from his functions for two years after the restoration of royalty, but eventually restored to them. In 1802, he went to Paris to direct the music of the consular chapel; but the indifferent reception shortly after given to his opera of *Proserpine*, led him to return to Naples, where he died in 1816. His compositions are characterised by sweetness and gracefulness of melody, and simplicity of structure. Besides no fewer than ninety operas, P. composed masses, requiems, cantatas, an oratorio, instrumental quartets, harpsichord sonatas, concertos, and a highly-praised funeral march in honour of General Hoche.

PAISLEY, a municipal and parliamentary burgh, and an important manufacturing town of Scotland, in the county of Renfrew, on both banks of the White Cart, three miles above its junction with the Clyde, and seven miles west-south-west of Glasgow by railway. The progress of the town has been much hindered by the fact that it was bankrupt for nearly thirty years. A bill was passed in 1872, by which

a settlement was effected, and the town property restored to the corporation. Since then, extensive improvements have been made. An abundant supply of water is brought from the Gleniffer Hills, and more recently from Rowbank.

By far the most interesting edifice is the abbey. It was founded by Walter, the High Steward of Scotland, about 1163, for a prior and 13 monks of the Cluniac order of reformed Benedictines, and was dedicated to St James, St Mirren, and St Milburga. It was the burying-place of the Stewarts before the accession of that family to the throne, and was occasionally used by them afterwards as a place of sepulture. It was raised to the rank of an abbey in 1245. It was burned by the English in 1307, and was much destroyed in 1561. The building is in the First Pointed style. The nave, of six bays, which is still used as the Abbey Pariah Church, was carefully and thoroughly restored by the removal of unsightly galleries and otherwise in 1862. The choir and transepts are in ruins. Near the Abbey is a monument to Wilson the ornithologist, who, like John Wilson (Christopher North) and Tannahill, were natives of Paisley.

Other edifices are the County Buildings and Prison, a quadrangular pile in the castellated style; the Neilson Educational Institution, a noble bequest, built in the form of a Greek cross, and surmounted by a fine dome; the Infirmary; the School of Design; and the various banks. The Grammar School was founded by King James VI., and the present building was completed in 1864. In 1870 a Free Public Library and Museum was presented to the town, and is maintained by the community under the Free Libraries Act; and by a similar act of liberality, its amenity was increased by a pleasure-ground named the Fountain Gardens. In 1873 a native of Paisley bequeathed £20,000 for the erection of a town hall, which was completed in 1880; it is a handsome classical building near the Abbey. A large public park was presented to the town, and opened in 1877; and an observatory was presented in 1882. P. possesses a trust for the education of boys, the revenue of which amounts to £500.

In the beginning of the last century, the principal manufactures were coarse linens and chequered cloths. About the middle of that century, the weaving of linen and of silk gauze became the staple manufactures. In 1784 silk gauze was manufactured to the value of £350,000, and employed 5000 looms. Shawls, which used to be a principal and are still an important article of manufacture, began to be made here in the beginning of the present century. Within recent years the annual value of the shawl trade of P. was estimated at about £1,000,000 sterling, but it has now greatly declined. Cotton thread is manufactured on a most extensive scale; indeed P. may be considered the seat of the thread manufacture for the home and American markets. Different varieties of tartan cloths, handkerchiefs, carpets, &c. are made; soap, starch, and corn flour are largely manufactured; dyeing is carried on by several firms on an extensive scale; and power-loom factories, print-works, machine shops, bleach-fields, ship-building yards, &c. are in operation in the town and vicinity. At the St James' Day Fair, horse-races, originated by act of the bailies of the burgh in 1608, are held. Pop. (1871) 48,257; (1881) 55,642.

PALACE, this title is applied, with few exceptions, in this country to houses occupied by royal personages only. In Italy the name is given to all fine dwellings.

PALACKY, FRANTISEK, a Bohemian philologist, critic, and historian, was born 14th June 1798 at Hodslavitz, in Moravia, and studied at Presburg

and Vienna, confining his attention chiefly to philological and historical investigations. In 1831 he was appointed by the states of Bohemia historiographer to that country, and was intrusted with the compilation of a general history of Bohemia. In furtherance of this work, he ransacked all the libraries and archives in Bohemia, and made long visits to Germany and Italy in search of materials. He took part in the political agitation of 1848, and was the leader of the Slav or national party as opposed to the German at the Diet of Kremsier, after the dissolution of which he returned to his literary labours. His great and justly celebrated work, *History of Bohemia* (in German and Bohemian, Prague, 1836—1867, 5 vols.), was received with enthusiasm by the whole Bohemian nation. Besides an early treatise on aesthetics, P. published many volumes of documents pertaining to Bohemian history, and a series of monographs on the same subject; a work on the most ancient monuments of the Czech tongue; an account of a literary tour to Italy in 1837; and in 1872 his 'Political Testament.' 'Father P.,' as he was fondly called by his Czech fellow-countrymen, was beloved by them as the first to give access to the real history of Bohemia; and though himself a Protestant, was regarded by Catholics with perfect confidence. Throughout life a zealous contender for the crown rights of Bohemia, he persistently but vainly opposed the reconstruction of Austria on a German-Hungarian basis; and when in 1861 he was elected into the Austrian House of Lords, he declined to attend. He died in May 1876.

PA'LADIN, a term originally derived from the Counts Palatine, or of the Palace (see **PALATINE**), who were the highest dignitaries in the Byzantine court, and thence used generally for a lord or chieftain, and by the Italian romantic poets for a knight-errant.

PALÆOCRUSTIC SEA. See **ARCTIC OCEAN**.

PALÆA'STER (Gr. ancient star-fish), a genus of star-fish peculiar to the Silurian period, which in general appearance resemble the living brittle stars, but really present so many anomalies, that they cannot be referred to any existing family.

PALÆOGRAPHY (Gr. *palaios*, old, and *graphê*, writing), the science of ancient writings. It comprehends not merely the art of reading them, but such a critical knowledge of all their circumstances as will serve to determine their age, if they happen to be undated, and their genuineness, in the absence of any formal authentication. For these purposes, the palæographer needs to be acquainted with the various substances, such as bark, leaves, skins, paper, &c., which have been used for writing; with the various manners of writing which have prevailed, and the changes which they have undergone; with the various forms of authenticating writings, such as seals, signets, cachets, signatures, superscriptions, subscriptions, attestations, &c., which have been employed at different times; with the various phases through which the grammar, vocabulary, and orthography of the language of the writing with which he is dealing, has passed; and with more or less, as the case may be, of the history, laws, institutions, literature, and art of the age and country to which the writing professes to belong.

Palæography may be said to have been founded by the learned French Benedictine, Jean Mabillon, whose *De Re Diplomatica*, first published in 1681 in one vol. fol., reprinted in 1709, and again in 1789, in 2 vols. fol., is still, perhaps, the most masterly work on the subject. Along with the *Nouveau Traité de Diplomatique* (Par. 1750—1765, 6 vols. 4to) of the Benedictines of St Maur, and the *Elle-*

ments de Paléographie (Par. 1838, 2 vols. 4to), by De Wailly, it is the great authority for French palaeography. Chassant's work (7th ed.) is also excellent. English palaeography is perhaps less favourably represented in Astle's *Origin and Progress of Writing* (1803), and Humphrey's work, than is Scottish palaeography in Anderson's and Ruddiman's *Diplomata Scotica* (1739). Muratori treats Italian palaeography in his great *Antiquitates Italicae Medii Aevi* (3d vol.); so does the *Diplomatica Pontificia* (1841) of Marino Marini. The palaeography of Greece is illustrated in the *Palaeographia Græca* (Par. 1708) of Montfaucon; and in Wattenbach's *Schrifttafeln* (1877). Arndt's *Schrifttafeln* (1878) for Latin are admirable. Good manuals for Greek are Gardthausen (1877), and Wattenbach (2d ed. 1877); for Latin, Wattenbach (3d ed. 1878). For Spanish, see Rodriguez (1738); and for German, Eckard (1742), Heumann (1745), Walther, Kopp (1817), and Leist, *Urkundenlehre* (1832). Biblical palaeography falls into that of Old Testament (Gesenius and many others) and New Testament (in which department Tischendorf's name is one of the best known). The great work on palaeography generally is the *Paléographie Universelle* (Par. 1839—1845, in 5 vols. fol.) of Silvestre. The publications of the Palaeographical Society are valuable. See BLACK LETTER, CONTRACTIONS, PALIMPSEST, PAPYRI.

PALÆOLITHIC AGE. See MAN.

PALÆOLOGUS, the name of an illustrious Byzantine family, which first appears in history about the 11th c., and attained to imperial dignity in the person of MICHAEL VIII. in 1260. This emperor successfully undertook many expeditions to Greece and the Archipelago, and used his utmost endeavours to heal the schism between the Roman and Greek Churches, though with exceedingly little success. His successor on the throne was his son ANDRONICUS II. (1282—1329), under whose reign the Turks commenced in earnest a series of assaults on the Byzantine dominions. Andronicus attempted to oppose them with a force composed of mercenaries, but his success was very doubtful, as these troops, with perfect impartiality, attacked both his enemies and his subjects. To pay them he was compelled to levy such imposts as went far to destroy Byzantine commerce. He associated his son, MICHAEL IX., with himself in the government, and was dethroned by his grandson, ANDRONICUS III. (1328—1341), an able warrior and wise ruler, who repeatedly defeated the Bulgarians, Tartars of the Golden Horde, and the Servians, and diminished the oppressive imposts of the previous reign. He was, however, unsuccessful against the Catalans in Greece, and the Turks during his reign ravaged Thrace as far as the Balkan. He was greatly esteemed by his subjects, and well merited the title of 'Father of his Country,' which they bestowed upon him. His son, JOHN VI. (1355—1391), a weak and voluptuous prince, attempted in vain both by force and bribery to stop the progress of the Turks; at last the pope, moved by his urgent entreaties, which were backed by a promise to submit the Greek Church to his (the pope's) supremacy, urged the Hungarians and Servians to arm in defence of the Greek emperor, but the result was only an additional triumph to Sultan Amurath. The imbecile emperor was several times deposed, and on his final reinstatement by the sultan, acknowledged himself as his vassal for the capital and a small tract along the Propontis and Black Sea. Indeed, so degraded had the Byzantines become, that they obeyed the Sultan Bajazet's summons to aid him in reducing Philadelphia, the last Greek stronghold in Asia Minor. His son, ANDRONICUS IV. (1355—

1373), who had been associated with him in the government, died in exile. MANUEL II. (1391—1425) pursued the same tactics as his father John VI., and with the same result. The allied army of the Hungarians, Germans, and French, which he had summoned to his aid against the Turks, was totally routed at Nicopolis by Bajazet, and Constantinople itself closely besieged. The invasion of Asia Minor by Timur, however, compelled the sultan to withdraw his whole force, and his subsequent defeat and capture at Angora in 1402, and the contests among his sons for the supremacy, gave the Greek empire a breathing space. Having aided Mohammed I. in his contests with his brothers, Manuel was, by the grateful sultan, presented with some districts in Greece, Thessalonica, and on the Euxine. JOHN VII. (1425—1449), on being pressed by the Turks, again held out to the pope the old bait of the union of the Greek and Western Churches under his sway, and even presented himself at the council of Florence, where, in July 1439, the union of the churches was agreed to. But on his return to Constantinople, the opposition of the Greek ecclesiastics to the union, supported by the people, rendered the agreement of Florence a dead letter. The pope, however, saw that it was for his interest to fulfil his part of the agreement, and accordingly stirred up Wladias of Hungary to attack the Turks (see JAGELLONS), but this act only hastened the downfall of the Palæologi. John's brother, CONSTANTINE XIII. (1449—1453), a heroic scion of a degenerate race, accepted the crown after much hesitation, knowing his total inability to withstand the Turks, and even then took the precaution of obtaining the sultan's consent before he exercised the imperial authority; but some rebellions in Caramania which now occurred, baffling Sultan Mohammed II.'s efforts to quell them, the emperor was willingly persuaded by his rash advisers that the time had now arrived for rendering himself independent of the Turks. The attempt, however, only brought swifter destruction on the wretched remnant of the Byzantine empire, for Mohammed invested the capital by sea and land, and after a siege, which lasted from 6th April to 29th May 1453, Constantinople was taken by storm, and the last of the Palæologi fell fighting bravely in the breach. A branch of this family ruled Montferrat in Italy from 1306, but became extinct in 1533. The Palæologi were connected by marriage with the ruling families of Hungary, Serbia, and the last of the family married Ivan, Czar of Russia—a fact which the Czars of Russia have persisted till lately in bringing forward as a claim in favour of their pretensions to the possession of European Turkey. It is said that direct descendants of the Palæologi exist to the present day in France. (For further information, see the separate articles on some of the emperors, and BYZANTINE EMPIRE.)

PALÆONISCUS (Gr. ancient sea-fish), a genus of ganoid fish, with a fusiform body, covered with rhomboid scales, a heterocercal tail, and moderately-sized fins, each furnished with an anterior spine.

Palæoniscus.

The single dorsal fin is opposite to the interval between the anal and ventral fins. Twenty-eight species have been described from the Carboniferous and Permian measures.

PALÆONTOLOGY (Gr. science of fossil animals) is that division of Geology (q. v.) whose province it is to inquire into the evidence of organic life on the globe during the different bygone geological periods, whether this evidence arises from the actual remains of the different plants and animals, or from recognisable records of their existence, such as footprints, Coprolites (q. v.), &c.

The metamorphic action which has so remarkably altered the oldest sedimentary rocks, is sufficient to have obliterated all traces of organic remains contained in them. Fossils are consequently extremely rare in these older palæozoic strata, and indeed it is only after long search, and within a recent time, that undoubted remains have been found in the Laurentian rocks. We were unable to record their existence in the article **LAURENTIAN SYSTEM**; but in the article **LIMESTONE**, we referred to the existence of beds of limestone as requiring the presence of animal life for their production. It is true that in 1852 an organic form resembling a coral was found in the limestone of the Ottawa, but much doubt was always entertained regarding this solitary discovery. In 1863, however, there was detected an organism in the serpentine limestone of Grenville, of true Laurentian age, which Dr Dawson describes as that of a Foraminifer, growing in large sessile patches, after the manner of *Carpentaria*, but of much greater dimensions, and presenting minute points, which reveal a structure resembling that of other foraminiferous forms, as, for example, *Calcarina* and *Nummulina*. Large portions of the limestone appear to be made up of these organisms, mixed with other fragments, which suggest comparisons with crinoids and other calcareous fossils, but which have not yet been distinctly determined. Some of the limestones are more or less coloured by carbonaceous matter, exhibiting evidences of organic structure, probably vegetable. In this single Foraminifer, and the supposed coral, we have all that is positively known of the earliest inhabitants of our globe, with which we are yet acquainted. That these are but the smallest fraction of the fauna of the period in which they lived, is evident from the undetermined fragments associated with them, as well as from the extensive deposits of limestone of the same age. And that contemporaneous with them, there existed equally numerous representatives of the vegetable kingdom, cannot be doubted, when it is remembered that the animal can obtain its food only through the vegetable, and not directly from inorganic materials. Besides, their remains apparently exist in the limestone at Grenville, a rock which, from its very nature, rarely contains vegetable fossils.

The Cambrian rocks, though of immense thickness, have hitherto yielded indications of only a very few animals, but these have a special interest, as they are the oldest fossil remains yet detected in Britain. They consist of an impression which Salter considers to be portion of a trilobite, named by him *Palaopyge*, of the burrows and tracks of sea-worms, and of two species of radiated zoophytes called *Oldhamia*—animals which in this case also can be nothing more than the most fragmentary representations of the fauna of the period. No indications of vegetable life have yet been noticed in the Cambrian rocks, for we cannot consider the superficial markings on some of these strata as having anything to do with fungi.

Undoubted representations of the four invertebrate sub-kingdoms early make their appearance in the Silurian strata, and the occurrence before the close of the period of several fish, adds to them the remaining sub-kingdom—the vertebrata. If we except the silicious frustules of Diatomaceæ which

are said to have been detected in these rocks, no satisfactory traces of plants have yet been observed, although extensive layers of anthracitic shales are common. Of the lower forms of the animal kingdom, some sponge-like bodies have been found, and corals are remarkably abundant, chiefly belonging to the order *Rugosa*, a palæozoic type, the members of which have horizontal tabulae, and vertical plates or septa, either four in number, or a multiple of four. Graptolites, another family of zoophytes, flourished in the dark mud of the Silurian seas, and did not survive the period. All the great divisions of the Mollusca are represented by numerous genera, several of which are not very different from some living forms. A few true star-fishes have left their records on the rocks, but the most striking feature in the Echinodermata of the period is the *Cystideans*, or armless sea-lilies, which, like the Graptolites, did not pass beyond the Silurian seas. Tubes, tracks, and burrows of annelids have been observed; and numerous Crustacea, belonging, with the exception of one or two shrimp-like species, to the characteristic palæozoic Trilobites, of which the number of individuals is as remarkable as the variety of species and genera. It is only in the upper portion of the group (the Ludlow beds) that the fish remains have been found. These have been referred to six different genera, and are chiefly loricate ganoids, of which *Cephalaspis* is the best known.

The rocks of the Old Red Sandstone period supply the earliest satisfactory remains of plants. The Ferns, Sigillaria, Lycopodites, and Calamites, so abundant in the Coal Measures, make their appearance among the newer of these beds, and even fragments of dicotyledonous wood have been observed. The various sections of the invertebrata are well represented, but the remarkable characteristic in the animal life of the period is the abundance of strange forms of heterocercal-tailed fish, whose buckler-shields, hard scales, or bony spines occur in the greatest abundance in some beds. The reptiles and reptile tracks in the Red Sandstone of Moray, originally referred here, are now universally considered as belonging to the New Red measures.

The striking feature in the rocks of the Carboniferous period is the great abundance of plants, the remains of which occur throughout the whole series, the coal-beds being composed entirely of them, the shales being largely charged with them, the sandstones containing a few, and even the limestones not being entirely without them. These plants were specially fitted for preservation, the bulk of them being vascular cryptogams, a class which Lindley and Hutton have shewn by experiment to be capable of long preservation under water. They are chiefly ferns; some are supposed to have been arborescent lycopods, while others (*Sigillaria*, *Calamites*, and *Asterophyllites*) are so different from anything now known, that their position cannot be definitely determined, though it is most probably among the higher cryptogams. Several genera of conifers have been established from fossilised fragments of wood; and some singular impressions, which look like the flowering stems of dicotyledonous plants, have been found. The limestones are chiefly composed of crinoids, corals, and brachiopodous shells. The corals attain a great size, and the crinoids are extremely abundant, their remains making sometimes beds of limestone 1000 feet thick, and hundreds of square miles in extent. Many new genera of shells make their appearance. The trilobites, which were so abundant in the earlier rocks, are reduced to one or two genera, and finally disappear with this period. Fish with polished bony scales are found; and others, like the Port Jackson shark, with pavements of flat teeth over their mouth and gullet,

fitting them to crush and grind the shell-protected animals on which they fed. Strange fish-like reptiles existed in the seas, and air-breathing species have been found on the continent and in America. The wing-cases, and parts of the bodies of insects, have also been found.

The Permian period is remarkable for the paucity of its organic remains, but this may arise from our comparative ignorance of its strata. The plants and animals are on the whole similar to those found in the Carboniferous measures, and a great proportion of them belong to the same genera. Many ancient forms do not pass this period, as the *Sigillaria* among plants, and the *Producta* among animals.

The red sandstones of the Triassic period are remarkably destitute of organic remains—the iron, which has given to them this colour, seems to have been fatal to animal life. In beds, however, on the continent, in which the iron is absent, fossils abound. These fossils present a singular contrast to those met with in the older rocks. The Palæozoic forms had been gradually dying out, and the few that were still found in the Permian strata do not survive that period, while in their place there appear in the Trias many genera which approach more nearly to the living forms. Between the organisms of the Permian and Triassic periods there exist a more striking difference than is to be found between those of any previous periods. Looking at this life-character, the rocks from the Permian downwards have been grouped together under the title Palæozoic; while from the Trias upwards the whole of the strata have received the name of Neozoic.

The extensive genera of *Ammonites* and *Belemnites* make their first appearance in the Trias. Several new forms of Cestracient fish occur, and the reptiles increase in number and variety; among them is the huge batrachian *Labyrinthodon*, and the singular fresh-water tortoise, *Dicynodon*. The bird-tracks on the sandstones of Connecticut are by some referred to this age. Small teeth of mammalia, believed to be those of an insectivorous animal, like the *Myrmecobius* of Australia, have been found in the Keuper beds of Germany and Somerset.

In the Oolitic series we have an abundance of organic remains, in striking contrast to the scanty traces in the Permian and Triassic periods. Many new genera of ferns take the place of the Palæozoic forms, and a considerable variety of Conifers make their appearance, some of which have close affinities with living species, one, indeed, being referred to a still existing genus. The same approximation to living types is to be found in the animal kingdom. Several of the foraminifers are referred to living genera. Among the corals, the representatives of two living families make their appearance. No new genera are found among the Brachiopoda; but the *Conchifera* and *Gasteropoda* shew a great addition of new genera, some of which are still represented by living species, while not many new genera were added to the Cephalopoda, though they were individually very abundant. In some places the Lias shale consists of extensive pavements of *Belemnites* and *Ammonites*. The Crinoids give place to the increasing variety of sea-urchins and star-fishes. Numbers of insects have been found. The Cestracients continue to be represented in the Oolitic seas, but with them are associated several true sharks and rays; and the homocercal-tailed fish become numerous. *Labyrinthodont* reptiles abound: the huge *Megalosaurus* and its companions occupied the land; while the seas were tenanted with the remarkable *Ichthyosaurus* and *Plesiosaurus*, and the air with the immense bat-like *Pterodactyle*. Seven

genera of Mammalia have been found, all believed to be small carnivorous or insectivorous marsupials, except the *Stereognathus*, which Owen considers to have been a placental mammal, probably hoofed and herbivorous.

In the Cretaceous beds, which are chiefly deep-sea deposits, the remains of plants and land animals are comparatively rare. The Wealden beds, however, which had a fresh-water origin, contain the remains of several small marsupials, some huge carnivorous and herbivorous reptiles, a few fresh-water shells, and some fragments of drift-wood. The true chalk is remarkably abundant in the remains of foraminifers—indeed, in some places, it is composed almost entirely of the shells of these minute creatures. Of the mollusca, the Brachiopoda are in some beds very abundant; the *Conchifera* introduce several new forms, the most striking of which is the genus *Hippurites*, which with its allies did not survive this period; the cephalopodous genera which appeared in the Oolite, continue to abound in the chalk, many new forms being introduced; while others disappear with the period, like the *Belemnites* and *Ammonites*. Sea-urchins become still more numerous. In some beds the remains of fish are abundant, and while cartilaginous species still exist, the bony fishes become more numerous; and among them the family to which the salmon and cod belong makes its appearance. Reptiles are common in the Wealden, and the flying *Pterodactyles* attained a greater size, and were probably more numerous than in the former period. The remains of a single bird has been obtained from the greensand, but with this exception, birds as well as mammals have left no traces that have yet been found in the Cretaceous beds, though doubtless they existed.

In the Tertiary strata, the genera are either those still living, or forms very closely allied to them, which can be separated only by the careful examination of the accurate scientific observer. The plants of the Eocene beds are represented by dicotyledonous leaves, and palm and other fruits. Foraminifers are remarkably abundant, whole mountain masses being formed of the large genus *Nummulites*. Brachiopoda are rare, but *Conchifera*, *Gasteropoda*, and *Cephalopoda* increase in number; the new forms being generically almost identical with those now living. The principal living orders of fish, reptiles, and birds are represented in the Eocene strata. A considerable variety of pachydermatous mammals, suited apparently to live on marshy grounds and the borders of lakes, have been found in France and England, and associated with them are some carnivorous animals, whose remains are, however, much rarer. An opossum has been found at Colchester. The fragments belonging to the supposed monkey are portions of a small pachyderm, *Hyrcotherium* (q. v.).

Little need be said of the invertebrata of the Miocene period, beyond remarking their growing identity in genera with the living forms. Among the mammals, the *Quadrumana* make their first appearance. The true elephant and the allied mastodon are represented by several species; a huge carnivorous whale has been discovered, and several *Carnivora* and deer, with a huge edentate animal, have been described. Owen thus speaks of these animals: 'Our knowledge of the progression of Mammalian life during the Miocene period, teaches us that one or two of the generic forms most frequent in the older Tertiary strata still lingered on the earth, but that the rest of the Eocene Mammalia had been superseded by new forms, some of which present characters intermediate between those of Eocene and those of Pliocene genera.'

In passing upwards through the Tertiary strata, the organic remains become more and more identical with living forms, so that when we reach the Pliocene and Pleistocene periods, the great proportion of the invertebrata are the same species which are found occupying the present seas. Among the higher orders of animals, the life of a species is much shorter than in the lower, and consequently, though the vertebrata approach so nearly to existing forms as for the most part to be placed in the same genera, yet the species differ from any of the living representatives of the different genera.

The Suffolk 'Crag,' which are the only British representatives of the Pliocene period, contain the relics of a marine testacea, that differs little from the present tenants of the European seas, between 60 and 70 per cent. being the same species. The ear-bones of one or more species of Cetacea have been found, and at Antwerp, the remains of a dolphin have been discovered in beds of this age.

The various local deposits which together form the Pleistocene strata, the latest of the geological periods, contain a great variety of organic remains. In the submarine forests, and in beds of peat, the stumps of trees are associated with the remains of underwood and herbaceous plants of species still living. Nearly all the molluscs and other marine invertebrata still survive. It is among the vertebrata that the most remarkable forms appear—forms which in the main differ little from the existing race of animals except in their enormous size. Elephants and rhinoceroses, fitted for a cold climate by their covering of long coarse hair and wool, roamed over the northern regions of both the Old and the New World, and were associated with animals belonging to genera which still exist in the same region, as bears, deer, wolves, foxes, badgers, otters, wolverines, weasels, and beavers, besides others whose representatives are now found further south, as the hippopotamus, tapir, and hyena. Contemporary with these, there lived in South America a group of animals which were types in everything but in size of the peculiar existing fauna of that continent. Among these were gigantic sloth-like animals, fitted to root up and push down the trees, instead of climbing to strip them of their foliage, like the sloth. The armadillo was represented by the huge Glyptodon, whose body was protected by a strong tessellated coat of mail. The species of fossil tapirs and peccaries are more numerous than their living representatives. The lamas were preceded by the large Macrauchenia, and the opossums and platyrrhine monkeys were also prefigured by related species. Besides these, there have been found the remains of two mastodons and a horse, none of which are represented by any indigenous living animal in South America. The peculiar group of animals confined to Australia were prefigured by huge marsupials, some having close analogies to the living kangaroos and wombats, while others were related to the carnivorous native tiger. The gigantic wingless birds of New Zealand correspond in type with the anomalous apteryx, now existing only on these islands.

Associated with the remains of elephants, mastodons, cave-bears, and cave-hyenas, there have been found, in England and France, numerous specimens of flint implements, which are undoubtedly the result of human workmanship, and shew at least that man was contemporaneous with these extinct animals. If more certain evidence were needed of this, it has been obtained in the discovery of flint implements, bone implements fashioned and carved by means of the flint knives, the horns of a reindeer, two kinds of extinct deer, *Bos primigenius*, and other animals, associated with numerous bones

of man, included in the breccia of the cave of Bruniquet in France. Owen considers the evidence of the contemporaneity of the various remains as conclusive. The several human skulls which have been obtained shew, according to the same authority, no characters whatever indicative of an inferior or transitional type. There are no certain data to give probability to the guesses which have been made as to the number of years which have elapsed since these deposits in which the relics of man occur were formed. The whole inquiry, moreover, is so recent, and the accumulation of facts is almost every day going on, that it would be premature to speak dogmatically on the subject.

PALÆOPYGE (Gr. ancient rump), a genus of fossil Crustacea, founded on a single impression from the surface of a bed in the Longmynd, of Cambrian age. Salter believes it to be the cephalic shield of a trilobite, but it may be only an accidental marking. If it be the impression of an organism, it is so distorted and imperfect that little can be made of it; its peculiar interest arises from its being associated with the earliest forms of life that have been observed on the globe.

PALÆOSAURUS (Gr. ancient lizard), a genus of fossil saurian reptiles peculiar to the Permian period. The remains of two species occur in the dolomitic conglomerate at Redland, near Bristol. The teeth were more or less compressed, and were furnished with serrated cutting margins. The vertebrae were biconcave, and had a remarkable depression in the centre of each vertebra, into which the spinal canal was sunk. The leg-bones shew that the Palæosaurs were fitted for moving on the land. Owen thus exhibits their affinities: 'In their thecodont type of dentition, biconcave vertebra, double-jointed ribs, and proportionate size of the bones of the extremities, they are allied to the Teleosaurus, but with these they combine a Dinosaurian femur, a lacertian form of tooth, and a crocodilian structure of pectoral and probably pelvic arch.'

PALÆOTHERIUM (Gr. ancient wild beast), a genus of pachydermatous mammalia whose remains occur in the Eocene beds of England and the continent. At least ten species have been described, ranging in size from that of a sheep to that of a horse. The upper Eocene gypseous quarries of Montmartre supplied the first scanty materials, which Cuvier, by a series of careful and instructive inductions, built up into an animal, whose fidelity to nature was afterwards verified by the discovery of a complete series of fossils. In general appearance the Palæotherium resembled the modern tapir, and especially in having the snout terminating in a short proboscis. It had three toes on each foot, each terminated by a hoof.—The formula of the teeth is the same as that of the Hyracothere, viz.,

$$I. \frac{3-3}{3-3}, C. \frac{1-1}{1-1}, P. M. \frac{4-4}{4-4}, M. \frac{3-3}{3-3} = 44;$$

but the structure of the molars approaches nearer to the molars of the rhinoceros. It is supposed that animals of this genus dwelt on the margins of lakes and rivers, and that their habits were similar to those of the tapir.

PALÆOZOIC (Gr. ancient life), the name given to the lowest division of the fossiliferous

Palæotherium.

rocks, because they contain the earliest forms of life. They were formerly, and are still generally, known as the Primary rocks. The strata included under these titles are the Laurentian, Cambrian, Silurian, Old Red Sandstone, Carboniferous, and Permian systems. Phillips, for the sake of uniformity, introduced Mesozoic as equivalent to Secondary, and Neozoic to Tertiary rocks.

PALÆSTRA, a building for gymnastic sports.

PALAFOX Y MELZI, Don José DE, Duke of Saragossa, a Spanish patriot, was born in 1780 of a distinguished Aragonese family, and received an excellent education. He accompanied Ferdinand VII. to Bayonne, and on seeing him made a prisoner there, fled to Saragossa, where he exerted himself to prevent the invasion of Aragon by the French. His defence of Saragossa (q. v.), 27th July 1808—21st February 1809, which only yielded to the French after a second investment, is one of the most brilliant and heroic incidents in modern history, and has conferred lasting glory on P. and the whole city. The ancient fame of the Spaniards for obstinate valour in the defence of walled cities was rivalled, if not surpassed, and Saragossa could proudly claim to vie with Numantia. P., sick and exhausted, was taken prisoner and conveyed by the ungenerous French to the dungeons of Vincennes, where he was treated with great hardship. Released in 1813, he returned to Spain, and was appointed in the following year captain-general of Aragon. P. was no great politician, but he loved liberty and hated anarchy, and on more than one occasion he supported the former and crushed the latter. After being created Duke of Saragossa, and Grande of Spain of the first class in 1836, he kept himself apart from politics. He died at Madrid, 16th February 1847.

PALAIS ROYAL, a heterogeneous mass of buildings on the eastern side of the Rue Richelieu in Paris, composed of a palace, theatres, public gardens, bazaars, shops, cafés, and restaurants. The old palace was built between 1624 and 1636 on the site of the Hôtel Rambouillet by Cardinal Richelieu, who at his death bequeathed it to Louis XIII. Henrietta of France, widow of Charles I., and Anne of Austria, the queen mother, afterwards lived in it for a time with her young son, Louis XIV. It subsequently became the town residence of the Orleans branch of the Bourbons, and during the minority of Louis XV. it acquired a scandalous notoriety as the scene of the wild orgies in which the regent, Duke of Orleans, and his dissolute partisans were wont to indulge; while in the time of his son, Philippe Egalité, it became the focus of revolutionary intrigue, and the rendezvous for political demagogues of every shade of opinion. This prince, partly to repair his impoverished fortune, and partly to persuade the sans-culottes of Paris of the sincerity of his professed sympathy with their striving for equality, converted part of his gardens into a place of public resort, and the pavilions of the great court into bazaars, which were divided into shops and stalls. On the downfall of Egalité, the P. R. was taken possession of by the republican government, and used for the sittings of the tribunes during the Reign of Terror. On the restoration of the Bourbons, it reverted to the Orleans family, and was occupied by Louis Philippe till his election to the throne of France in 1830, when it was incorporated in the general domains of the state, and ceased to be an appanage of the House of Orleans. The palace was sacked by the mob during the Revolution of 1848, when many of its best paintings and most precious works of art were destroyed. After having been temporarily appropriated to various public purposes, it was

thoroughly repaired and magnificently furnished, and given by the late emperor, in 1855, to his uncle Jerome Bonaparte, whose son Prince Napoleon resided there until 1871. The main entrance, with its elegant façade, is in the Rue St Honoré; and on passing through the first court, the second or Cour Royale is reached, to the left of which stands the Théâtre Français, while immediately facing it is the celebrated Galerie Vitree, or Glass Gallery, which contains on the ground floor some of the most brilliant shops of Paris, while the upper stories are chiefly occupied by cafés and restaurants. The garden, which is surrounded by this and other galleries, measures 700 feet by 300. The Red Republicans set fire to the palace in March 1871 (see PARIS), when all the apartments occupied by Prince Napoleon were destroyed. The firemen and those who aided them, while forming into line to pass buckets of water, were fired upon by the insurgents; but kept to their work, and succeeded in checking the flames before they spread to the galleries and shops, which may almost be said to have remained intact. In the autumn of 1873 that part of the palace injured by the insurgents was restored. The garden, with its avenues and parterres, fountains and grass plots, still constitutes one of the liveliest and most frequented spots in the whole city; and although much of their glory has faded, its cafés still maintain, in great measure, the world-wide reputation they long ago acquired.

PALANQUIN, or **PALKI**, the vehicle commonly used in Hindustan by travellers, is a wooden box, about 8 feet long, 4 feet wide, and 4 feet high, with wooden shutters which can be opened or shut at pleasure, and constructed like Venetian blinds for the purpose of admitting fresh air, while at the same time they exclude the scorching rays of the sun, and the heavy showers of rain so common in that country. The furniture of the interior consists of a cocoa mattress, well stuffed and covered with morocco leather, on which the traveller reclines; two small bolsters are placed under his head, and one under his thighs, to render his position as comfortable as possible. At the upper end is a shelf and drawer, and at the sides are nettings of larger dimensions than the ordinary pockets in carriages, for containing those articles which may be necessary to the traveller during his journey. At each end of the palanquin, on the outside, two iron rings are fixed, and the *hammala*, or palanquin-bearers, of whom there are four, two at each end, support the palanquin by a pole passing through these rings. Travelling in this mode is continued both by day and night. (See DAWK.) The palanquin is also used at the present day in Brazil, with the prominent exception of Rio Janeiro.

Similar modes of travelling have been at various times in use in Western Europe, but only for short distances. The Roman 'litter', the French 'chaise a porteurs', and the 'sedan-chair' were the forms of vehicle most in use, and the two latter were in general use in towns till they were superseded by hackney coaches. The Roman 'litter' was one of the criteria of its owner's wealth, the rich man generally exhibiting the prosperous condition of his affairs by the multitude of the bearers and other attendants accompanying him.

PALAPTERYX (Gr. ancient apteryx), a genus of fossil birds whose remains are found in the river-silt deposits of New Zealand, associated with the gigantic *Dinornis*, and which, like it, resembled in the form of the sternum, and the structure of the pelvis and legs, the living wingless apteryx. Two species have been described.

PALATE, THE, forms the roof of the mouth, and consists of two portions, the hard palate in front and the soft palate behind. The framework of the *hard palate* is formed by the palate process of the superior maxillary bone, and by the horizontal process of the palate bone, and is bounded in front and at the sides by the alveolar arches and gums, and posteriorly it is continuous with the soft palate. It is covered by a dense structure formed by the

The Mouth widely opened so as to shew the Palate :

- 1, 1, the upper, and 2, the lower lip; 3, 3, the hard palate; 4, 4, the soft palate; 5, the uvula; 6, 6, the arches of the soft palate; 7, 7, the tonsils; 8, the tongue.

periosteum and mucous membrane of the mouth, which are closely adherent. Along the middle line is a linear ridge or raphe, on either side of which the mucous membrane is thick, pale, and corrugated, while behind it is thin, of a darker tint, and smooth. This membrane is covered with scaly epithelium, and is furnished with numerous follicles (the palatal glands). The *soft palate* is a movable fold of mucous membrane enclosing muscular fibres, and suspended from the posterior border of the hard palate so to form an incomplete septum between the mouth and the pharynx; its sides being blended with the pharynx, while its lower border is free. When occupying its usual position (that is to say, when the muscular fibres contained in it are relaxed), its anterior surface is concave; and when its muscles are called into action, as in swallowing a morsel of food, it is raised and made tense, and the food is thus prevented from passing into the posterior nares, and is at the same time directed obliquely backwards and downwards into the pharynx.

Hanging from the middle of its lower border is a small conical pendulous process, the *uvula*; and passing outwards from the uvula on each side are two curved folds of mucous membrane containing muscular fibres, and called the *arches* or *pillars* of the *soft palate*. The *anterior pillar* is continued down-

wards to the side of the base of the tongue, and is formed by the projection of the palato-glossus muscle. The *posterior pillar* is larger than the anterior, and runs downwards and backwards to the side of the pharynx. The anterior and posterior pillars are closely united above, but are separated below by an angular interval, in which the *tonsil* of either side is lodged. The tonsils (*amygdalæ*) are glandular organs of a rounded form, which vary considerably in size in different individuals. They are composed of an assemblage of mucous follicles, which secrete a thick grayish matter, and open on the surface of the gland by numerous (12 to 15) orifices.

The space left between the arches of the palate on the two sides is called the *isthmus of the fauces*. It is bounded above by the free margin of the palate, below by the tongue, and on each side by the pillars of the soft palate and tonsils.

As the upper lip may be fissured through imperfect development (in which case it presents the condition known as hare-lip), so also may there be more or less decided fissure of the palate. In the slightest form of this affection, the uvula merely is fissured, while in extreme cases the cleft extends through both the soft and hard palate as far forward as the lips, and is then often combined with hare-lip. When the fissure is considerable, it materially interferes with the acts of sucking and swallowing, and the infant runs a great risk of being starved; and if the child grows up, its articulation is painfully indistinct. When the fissure is confined to the soft palate, repeated cauterisation of the angle of the fissure has been found sufficient to effect a cure by means of the contraction that follows each burn. As a general rule, however, the child is allowed to reach the age of puberty when the operation of *staphyloraphy* (or suture of the soft parts) is performed—an operation always difficult, and not always successful. For the method of performing it, the reader is referred to the *Practical Surgery* of Mr Fergusson, who has introduced several most important modifications into the old operation.

Acute inflammation of the tonsils, popularly known as **QUINSY**, is treated of in a separate article.

Chronic enlargement of the tonsils is very frequent in scrofulous children, and is not rare in scrofulous persons of more advanced age, and may give rise to very considerable inconvenience and distress. It may occasion difficulty in swallowing, confused and inarticulate speech, deafness in various degrees from closure of the eustachian tubes (now often termed *throat deafness*), and noisy and laborious respiration, especially during sleep; and it may even cause death by suffocation, induced by the entanglement of viscid mucus between the enlarged glands. Iodide of iron (especially in the form of *Blancard's Pills*) and cod-liver oil are the medicines upon whose action most reliance should be placed in these cases, while a strong solution of nitrate of silver (a scruple of the salt to an ounce of distilled water), or some preparation of iodine, should be applied once a day to the affected parts. If these measures fail, the tonsils must be more or less removed by the surgeon, either by the knife or scissors, or by a small *guillotine* specially invented for the purpose.

Enlargement or relaxation of the uvula is not uncommon, and gives rise to a constant tickling cough, and to expectoration, by the irritation of the larynx which it occasions. If it will not yield to astringent or stimulating gargles, or to the stronger local applications directed for enlarged tonsils, its extremity must be seized with the forceps, and it

must be divided through the middle with a pair of long scissora.

PALATINATE, a name applied to two German states, which were united previously to the year 1620. They were distinguished as the Upper and Lower Palatinate. The Upper or Bavarian P., now forming a circle of the kingdom of Bavaria, was a duchy, and was bounded by Baireuth, Bohemia, Neuburg, Bavaria, and the district of Nürnberg. Area, 2730 square miles; pop. (1807) 283,800. Amberg was the chief city, and the seat of government. The Lower P., or the Palatinate on the Rhine, embraced an area of from 8045 to 8150 square miles; and consisted of the electoral P., the principality of Simmern, the duchy of Zweibrücken, the half of the county of Sponheim, and the principalities of Beldenz and Lautern. For the area and population of the modern provinces of the Upper and Lower P., see article **BAVARIA**.

The counts of the electoral or Rhenish P. were established in the hereditary possession of the territory of that name, and of the lands attached to it, as early as the 11th century. After the death of Herman III., the Emperor Friedrich I. assigned the P. to Conrad of Swabia. After Conrad's death, his son-in-law, Duke Henry of Brunswick, came, in 1196, into the possession of these lands, but he, having been outlawed in 1215 by Friedrich II., was succeeded by his son, Otto III., Duke of Bavaria. Ludwig II., or the Strong, succeeded the preceding in the P. in 1253, and was in turn succeeded in 1294 by Rudolf I., who, however, was banished by his brother, the Emperor Ludwig, because he had taken part with Friedrich of Austria. The country was ruled by his three sons. Ruprecht III., who died in 1410, was a German emperor. Of his four sons, Ludwig III. received the electoral or Rhenish P.; Johann, the Upper P.; Stephan, Zweibrücken; and Otto, Mosbach. The second and fourth lines soon died out, as well as also that of Ludwig III., which came to a close in 1559, upon which the possessions of that prince, together with the electorate, passed to Friedrich III. of the Simmern line. He was succeeded by Ludwig IV. in 1576, by Friedrich IV. in 1583, and by Friedrich V. in 1610, who, after he accepted the Bohemian crown, was driven from his possessions by the emperor in 1619, and his office of elector was transferred to Maximilian, Duke of Bavaria. Karl Ludwig, son of Friedrich V., received the Lower P. at the peace of Westphalia, and in his favour a new or eighth electorship was created. With his son Karl, the Simmern line terminated in 1685, upon which the P. fell into the hands of Philipp Wilhelm, count palatine of Neuburg.

The House of Neuburg was descended from Ludwig the Black, count palatine in Zweibrücken, second son of Stephan, count palatine in Simmern. Wolfgang, a descendant of Ludwig's, was the founder of all the other lines of counts palatine. Of his three sons, Johann founded the line of Neu-Zweibrücken, Karl the Birkenfeld line, Philipp Ludwig the Neuburg line. Philipp Ludwig had three sons, Wolfgang Wilhelm, August, and Johann Friedrich. The first founded the Neuburg line, the second the Sulzbach line, the third died childless. The son of Wolfgang Wilhelm died in 1690. His son, Johann Wilhelm, became heir to the Beldenz line in 1694. He was succeeded by his brother, Karl Philipp, who in turn was succeeded in 1742 by Karl Theodor, from the Sulzbach line, who united the Bavarian territories with the Palatinate. Duke Maximilian of Zweibrücken next succeeded in 1799, who at the peace of Luneville (1801) was compelled to cede a portion of the Rhenish P. to France, a part to Baden, a part to Hesse-Darmstadt, and a

part to Nassau. Treaties of Paris of 1814 and 1815 re-assigned the Palatinate lands beyond the Rhine to Germany, Bavaria receiving the largest share, and the remainder being divided between Hesse-Darmstadt and Prussia.

PALATINE (from Lat. *palatium*, a palace). A *Comes Palatinus*, or Count Palatine, was, under the Merovingian kings of France, a high judicial officer, who had supreme authority in all causes that came under the immediate cognizance of the sovereign. After the time of Charlemagne, a similar title was given to any powerful feudal lord, to whom a province, generally near the frontier, was made over with *jura regalia*, or judicial powers, similar to what the counts palatine had received in the palace, and the district so governed was called a *palatinate* or *county palatine*. There were three counties palatine in England—Lancaster, Chester, and Durham—which were, no doubt, made separate regalties on account of their respective proximity to the frontier of Wales and to that turbulent Northumbrian province which could neither be accounted a portion of England nor of Scotland. In virtue of their regal rights, the counts palatine had their courts of law, appointed their judges and law officers, and could pardon treasons, murders, and felonies; all writs and judicial process proceeded in their names, and the king's writs were of no avail within the bounds of the palatinate. Lancaster seems to have been made a county palatine by Edward III. Henry, first Duke, and John, second Duke of Lancaster, were both invested by him with the dignity of count palatine. Henry VI. was hereditarily Duke and Count Palatine of Lancaster, and on his attainder, soon after Edward IV.'s accession, the duchy and county were forfeited to the crown, and confirmed on Edward IV.—afterwards on Henry VII. and his heirs for ever. The Queen is now Duchess and Countess Palatine of Lancaster. There is still a chancellor of the duchy and county palatine, whose duties are few and unimportant, but the administration of justice has gradually been assimilated to that of the rest of England. See **LANCASTER**. Chester is supposed to have become a county palatine when made over with regal jurisdiction by William the Conqueror to Hugues d'Avranches. In the reign of Henry III. it was annexed to the crown by letters patent, and since that time the earldom palatine of Chester has been vested in the eldest son of the sovereign, or in the crown, whenever there is no Prince of Wales. Durham seems to have first become a palatinate when William the Conqueror constituted Bishop Walcher Bishop and Duke of Durham, with power (according to William of Malmesbury) to restrain the rebellious people with the sword, and reform their morals with his eloquence. The Palatinate jurisdiction continued united with the bishopric till 1836, when it was separated by act of parliament, and vested in William IV. and his successors as a franchise distinct from the crown, together with all forfeitures, mines, and *jura regalia*. It has since been more completely incorporated with the crown. Pembroke was at one time a county palatine, but ceased to be so in Henry VIII.'s time. The Archbishop of York also exercised the powers of a palatine in the county of Hexham in Northumberland, of which he was deprived in the reign of Elizabeth. In very early times there were a number of similar privileges in Scotland, the most important of which was that of the Earls Palatine of Strathern. In Germany, the *Pfalzgraf*, or count palatine, exercised a jurisdiction much more extensive than the simple *Graf* or count. A considerable district in Germany was long under the jurisdiction of a count palatine,

who was one of the electors of the empire. See **PALATINATE**.

PALATINE HILL (*Mons Palatinus*), the central hill of the famous seven on which ancient Rome was built, and, according to tradition, the seat of the earliest Roman settlements. In point of historical interest, it ranks next to the Capitol and the Forum. Its summit is about 160 feet above the sea. The form of the hill is irregularly quadrangular. Its north-western slope, towards the Capitoline Hill and the Tiber, was called *Germalus* or *Cermalus*. The origin of the name is uncertain, although several derivations are given connecting it with legendary stories. Romulus is said to have founded the city upon this hill, and on Germalus grew the sacred fig-tree (near to the Lupercal) under which he and his brother, Remus, were found sucking the she-wolf. Upon the P. H. were the temple of Jupiter *Stator*, the temple of Cybele, the sacred square enclosure called *Roma Quadrata*, and other sacred places and edifices, besides many of the finest houses in Rome. Augustus and Tiberius had their residences here, whence Tacitus termed it *ipæ imperii arx* (the very citadel of government); and at last Nero included it entirely within the precincts of his *aurea domus*, which Vespasian subsequently restricted to the hill. From the time of Alexander Severus it ceased to be the residence of the emperors, but the name *palace* (*palatium*), derived from it, was given to the abodes of sovereigns and great princes, and has been adopted into modern languages. Recent excavations have brought to light numerous remains of the palatial and other structures with which the P. H. was once covered; and these are now among the most interesting sights of the eternal city.

PALAWAN, or **PARAGOA**, one of the Philippine Islands (q. v.).

PALE, in Heraldry, one of the figures known as ordinaries, consisting of a perpendicular band in the middle of the shield, of which it is said to occupy one-third (No. 1). Several charges of any kind are said to be 'in pale' when they stand over each other perpendicularly, as do the three lions of England. A shield divided through the middle by a perpendicular line is said to be 'parted per pale.' The Pallet is the diminutive of the pale, and is most generally not borne singly. No. 2, Or three pallets gules, were the arms of Raymond, Count of Provence. When the field is divided into an even number of parts by perpendicular lines, it is called 'paly of' so many

pieces, as in No. 3, Paly of six argent and gules, the arms of the family of Ruthven. When divided by lines perpendicular and bendways crossing, it is called paly bendy, as in No. 4. An Endorse is a further diminutive of the pallet, and a pale placed between two endorses is said to be endorsed (No. 5).

PALE, in Irish history (see **IRELAND, HISTORY**), means that portion of the kingdom over which the English rule and English law was acknowledged. There is so much vagueness in the meaning of the term, that a few words of explanation appear necessary. The vagueness arises from the great fluctuations which the English authority underwent in Ireland at various periods, and from the consequent fluctuation of the actual territorial limits of the Pale. The designation dates from the reign of John, who distributed the portion of Ireland then nom-

inally subject to England into twelve counties palatine, Dublin, Meath, Kildare, Louth, Carlow, Kilkenny, Wexford, Waterford, Cork, Kerry, Tipperary, and Limerick. To this entire district, in a general way, was afterwards given the designation of the Pale. But as it may be said that the term is commonly applied by the writers of each age to the actual English territory of the period, and as this varied very much, care must be taken to allude to the age of which the name Pale is used. Thus, very soon after the important date of the Statute of Kilkenny, at the close of the reign of Edward III., the English law extended only to the four counties of Dublin, Carlow, Meath, and Louth. In the reign of Henry VI., the limits were still further restricted. In a general way, however, the Pale may be considered as comprising the counties of Dublin, Meath, Carlow, Kilkenny, and Louth. This, although not quite exact, will be sufficient for most purposes.

PA'LEA (Lat. chaff), a term employed in Botany to designate the bracts of the *florets* in Grasses (q. v.), called *corolla* by the older botanists; also to designate the small bracts or scales which are attached to the receptacle of the head of flowers in many of the *Compositæ* (q. v.). Any part of a plant covered with chaffy scales is described as *paleaceous*.

PALEMBANG, formerly an independent kingdom on the east coast of Sumatra, now a Netherlands residency, is bounded on the N. by Djambi, N.W. by Bencoolen, S. by the Lampong districts, and S.E. by the Strait of Banca, has an area of 61,900 square miles; and a population amounting to about 600,000 souls. Much of the land is low-lying swamp, covered with a wilderness of impenetrable bush; but in the south it rises into mountains, of which Oeloe Moesi (Ulu Musi) is 6180 feet. Gold-dust, iron-ore, sulphur with arsenic, lignite, and common coal are found; also clays suited for making coarse pottery, &c. Springs of pure oil occur near the coal-fields of Bali Boekit (Bukit), and of mineral water in various places. Rice, cotton, sugar, pepper, tobacco, and, in the interior, coco-nuts, are grown; the forests producing gutta-percha, gum-elastic, ratans, wax, benzoin, satin-wood, &c. The rivers abound with fish; and the elephant, rhinoceros, tiger, panther, and leopard roam the woods, as well as the deer, wild swine, and goats, with many varieties of the monkey.

In the dry season the thermometer ranges from 80° to 92° F., and in the rainy season 76° to 80°. The climate is not unhealthy, except in the neighbourhood of the swamps. The natives are descended from Javanese, who in the 16th c., or earlier, settled in P., and ruled over the whole land. The race, however, has become mixed with other Malays, and the language has lost its purity. In the north-west interior is a tribe called the Koeboes (Kábûs), of whose origin nothing is known, but who are probably the remainder of the aborigines. They do not follow after agriculture, go about almost naked, and live chiefly by fishing and hunting. No idea of a Supreme Being seems to be possessed by them, though they believe in existence after death.

PALEMBANG, the capital of the kingdom and residency, is 52 miles from the Soensang (Sunsang), or principal mouth of the river Moesi (Musi), in 2° 59' S. lat., and 104° 44' E. long. The city is built on both banks of the Moesi, and other streams which fall into it, and is five miles in length by half a mile in breadth. The river is upwards of 1000 feet broad, and from 40 to 50 feet in depth, so that the largest vessels can sail up to the harbour. The native houses are raised on posts, and neatly constructed of planks or bamboos; the Chinese, Arabians, and Europeans, chiefly living in floating

houses called rakits, of which there are upwards of 500, and holding communication with one another and with the natives by boats. The fort is built on the left bank of the river, and behind it are an institution for the blind and a splendid mosque. There is a school, where 30 European children are educated, a government elementary school for natives, and several good Chinese schools. Many of the natives can read and write, and in 1856 a native printing-press was erected by Kemas Mohamed Asahel.

P. is visited annually by upwards of 30,000 boats of various sizes, bringing produce from the interior, consisting chiefly of rice, benzoin, gum-elastic, gutta-percha, raw cotton, rattans, tobacco, pepper, wax, dragon's blood, resin; and gold-dust from the boundaries of the kingdom of Djambi, now included in the Residency. These are obtained chiefly in exchange for salt, cotton manufactures, earthenware, iron and copper wares, and provisions. The foreign trade is large, and chiefly carried on with Java, Banca, Singapore, China, and Siam. The imports into P., which considerably exceed the exports thence, have an average annual value of near £300,000. The natives of P. are good ivory carvers, gold and silver smiths, jewellers, cutlers, japanners, painters, boat-builders, bookbinders, &c., and expert at all the ordinary handicrafts. The women, in addition to cotton fabrics, spinning, and dyeing, weave silk stuffs embroidered with gold. Pop. 44,000, of whom 100 are Europeans, 3000 Chinese, and 2000 Arabians.

PALENCIA (the ancient *Pallantia*), a city of Spain, in Old Castile, capital of the modern province of the same name, stands in a treeless, but well-watered and fruitful plain, on the Carrion, 30 miles north-east of Valladolid. It is a bishop's see, and is surrounded by old walls, 36 feet high and 9 feet thick, around which are pleasant promenades. The cathedral, a light and elegant Gothic edifice, was built 1321—1504. The first university founded in Castile was built here in the 10th c., but was removed to Salamanca in 1239. Nearly one-third of the population is employed in the manufacture of blankets and coarse woollen cloths. The position of the town on the Carrion, and on the Castilian Canal, is favourable to the development of commerce. The vine is cultivated, and there is a good trade in wool. Pop. (1877) 14,505.

PALENQUÉ, RUINS OF, are on the Rio Chacamas, a branch of the river Usumasinta, in the state of Chiapas, Mexico, 8 miles south-east of the village of Santo Domingo de Palenque, lat. 17° 30' N., long. 92° 25' W. The ruins extend over a large area, covered with a dense tropical forest, and are of difficult exploration. They consist of vast artificial terraces, or terraced truncated pyramids, of cut stone, surmounted by edifices of peculiar and solid architecture, also of cut stone, covered with figures in relief, or figures and hieroglyphics in stucco, with remains of brilliant colours. Most of the buildings are of one story, but a few are two, three, and some may have been four stories. The principal structure, known as the Palace, is 228 feet long, 180 feet deep, and 25 feet high, standing on a terraced truncated pyramid of corresponding dimensions. It was faced with cut stone, cemented with mortar of lime and sand, and the front covered with stucco and painted. A corridor runs around the building, opening into four interior courts, which open into many smaller rooms. On slabs of stone are carved numerous colossal figures, and the remains of statues more resemble Grecian than Egyptian or Hindu art. Other spacious and elaborately ornamented buildings appear to have been temples of

religion. These ruins were in the same condition when Cortez conquered Mexico, as now, overgrown with a forest, and their site forgotten. They were only discovered in 1750. Three explorations were made by the Spanish government, but they were little known until visited by Messrs J. L. Stephens and F. Catherwood, and their account published with plans and drawings. See Stephens's *Incidents of Travel in Central America, &c.*, and Catherwood's *Views of Ancient Monuments of Central America, &c.* There are in Mexico dim traditions of the existence, at a remote period, of the capital of a theocratic state, the centre of a long since extinguished civilisation, of which the only traces are these wonderful ruins and unexplained hieroglyphics.

PALERMO, an archiepiscopal city, important seaport, and the capital of the island of Sicily; capital also of the province of the same name, and along with Naples, Rome, Milan, and Turin, one of the five most populous cities in the kingdom of Italy, is situated on the north coast of the island, 135 miles by water west of Messina. Lat. 38° 6' N., long. 13° 20' E. It stands in a highly-cultivated and fertile plain called *La Conca d'Oro* (The Golden Shell), commands a beautiful view of the Gulf of Palermo on which it stands, and is backed toward the interior by ridges of mountains. In shape the town is an oblong parallelogram, the direction of its length being from south-west to north-east. It is divided into four quadrangular parts by two great streets, the beautiful *Via Vittorio Emanuele*, formerly the *Via Toledo* or *Cassaro*, and the *Strada Nuova* or *Maqueda*, which cross each other at right angles in the middle of the city. It is upwards of four miles in circumference, is surrounded by walls pierced with 12 gates and flanked with bastions, and is defended by several batteries. The houses are balconied, flat roofed, and have glass doors instead of windows. The streets, besides the two main thoroughfares already mentioned, are generally well laid out, and there are several fine promenades, of which the famous *Marina*, extending along the shore, on the line of the ancient fortifications, and bordered by the palaces of the nobles, is the most magnificent. P. contains 60 parish churches; 8 abbeys; 71 monasteries and convents, to which belong from 20,000 to 30,000 monks and nuns; and, besides these, 19 oratories. Under the churches is counted the cathedral—the church of St Rosalia. At the intersection of the two principal streets there is a large octagonal space or *Piazza*, lined with palaces, and adorned with statues and marble fountains. The royal palace is a huge pile of buildings, with a splendid chapel, built in 1129, and contains many pillars of rare workmanship and rich mosaics with Arabic inscriptions. The cathedral is a fine edifice, originally Gothic, but to which incongruous Greek additions have been made, is adorned with marble columns and statues, and contains monuments of the Emperor Frederick II. and of King Roger, the founder of the Norman monarchy in Sicily. Among the principal public institutions of P. are the university, an academy of arts and sciences, a medical academy, an institution for arts and antiquities, a beautiful and extensive public garden, public libraries, theatres, &c. P. is an archbishop's see, the residence of the governor of the island, and the seat of the supreme courts. Manufactures of silks, cottons, oil-cloth, leather, gloves, &c., are carried on. The harbour is formed by a mole, 1300 feet in length, on which there is a light-house and battery. Vessels of 700,000 tons enter and clear the port annually, and the imports amount in value to near £1,000,000, and the exports to about

the same sum. Pop. (1871) of P. with suburbs, 186,406; (1881) 205,712.

The environs of P. are interesting as well as picturesque, and embrace many pleasant villas and noble mansions. North-west of the city is Monte Pellegrino, the Eireto of the ancients, an abrupt rocky mass, in which there is a grotto or cave, in which Santa Rosalia, a young Norman princess, lived a life of religious retirement. In P., Santa Rosalia is esteemed more highly than even Santa Maria; the festival in her honour lasts from the 9th to the 13th July, and is the most important festival held on the island. During its celebration the city is illuminated, the streets are gay and brilliant, and there is an immense influx of strangers from the vicinity. But the chief feature of the festival is the procession to the cave. An immense silver image of the saint is borne thither on a wagon, 70 feet long, 30 feet broad, and 80 feet high. Its form resembles that of a Roman galley, with seats for a choir. The wagon is drawn by 56 mules, covered with the gayest trappings, and driven by 28 postillions.

P., the ancient *Panormus*, was originally a Phœnician colony, but had become a dependency of Carthage before the name occurs in history. With the exception of a short time about 276 B.C., when it fell into the hands of the Greeks, it continued to be the head-quarters of the Carthaginian power in Sicily, until it was taken by the Romans during the First Punic War (254 A.C.), when it became one of the principal naval stations of the Romans. The name *Panormus* is derived from the excellent anchorage (Gr. *hormos*) in the bay; but the Phœnician name found on coins is *Machanath*, meaning 'a camp.' The Vandals, and afterwards the Arabs, made it the capital of the island, and after the Norman Conquest it continued to be the seat of the king of Sicily. It still remained the royal residence under the Aragonese kings; but the court was removed after Sicily became united to the then kingdom of Naples. See SICILY.

PALESTINE (*Palæstina*, *Philistia*), or the **HOLY LAND**, a country of South-Western Asia, comprising the southern portion of Syria, and bounded on the W. by the Mediterranean, E. by the valley of the Jordan, N. by the mountain-ranges of the Lebanon and the glen of the Litány (Leontes), and S. by the Desert of Sinai; lat. 31° 15'—33° 20' N., long. 34° 30'—35° 30' E. Within these narrow limits, not more than 145 miles in length by 45 in average breadth—an area less than that of the principality of Wales—is comprised the 'Land of Israel' or 'Canaan,' the arena of the greatest events in the world's history. The principal physical features of P. are, (1) a central plateau or table-land, with a mean height of 1600 feet, covered with an agglomeration of hills, which extend from the roots of the Lebanon to the southern extremity of the country; (2) the Jordan valley and its lakes; and (3) the maritime plain, and the plains of Esdraelon and Jericho. On the east, the descent from the central plateau is steep and rugged, from Lake Huleh to the Dead Sea. On the west, it is more gentle, but still well marked, towards the plains of Philistia and Sharon. The ascertained altitudes on this plateau, proceeding from south to north, are Hebron, 3029; Jerusalem, 2610; Mount of Olives, 2724; Mount Gerizim, 2349; Mount Tabor, 1843; Safed, 2775 feet above the sea. Nearly on the parallel of the Sea of Galilee, the range of Carmel extends from the central plateau north-west to the Mediterranean, where it terminates abruptly in a promontory surmounted by a convent. It rises from 600 feet in the west, to 1810 feet in the east, and is composed of a soft white limestone, with many caverns. Beyond the bound-

dary of P. on the north, but visible from the greater part of the country, Mount Hermon rises to 9381 feet, and is always snow-clad. From the formation of the central plateau, the drainage is nearly always east and west, to the Jordan and the Mediterranean. The streams of the plateau are insignificant, and generally dry in summer.

The geological formation of the country consists of jurassic and cretaceous limestone, often covered with chalk, and rich in flints, with occasional interruptions of tertiary, basaltic, and trappean deposits. The upper strata consist of limestone of a white or pale-brown colour, containing few fossils, but abounding in caverns, which form one of the peculiarities of the country. The general features of the landscape exhibit soft rounded hills, separated by narrow glens or valleys of denudation; the strata are occasionally level, but more frequently violently contorted, as seen on the route from Jerusalem to Jericho, where the fissures are often 1000 feet deep, and only 30 or 40 feet wide. Ironstone occurs in small quantities; rock-salt, asphaltum, and sulphur abound near the Dead Sea, where, as also near the Sea of Galilee, there are many hot springs. Volcanic agency is evident in the obtruded lava of former ages, and in frequent earthquakes of modern times. The vast crevasses through which the Jordan flows, and which cleaves the land from north to south, is one of the most remarkable fissures on the surface of the globe; it is from 5 to 12 miles wide, and of the extraordinary depth of 2630 feet at the bottom of the Dead Sea. Through this the river descends at the rate of 11 feet in a mile, with a course so tortuous that it travels 132 miles in a direct distance of 64, between the Sea of Galilee and the Dead Sea. It is the only perennial river of P., except the Kishon, which is permanent only in its lower course, and the Litány on its northern border. See JORDAN. The only lakes of P. are in the valley of the Jordan. See GENNESARET, SEA OF, and DEAD SEA.

The plain of Philistia extends from the coast to the first rising ground of Judah, about 15 miles in average width; the soil is a rich brown loam, almost without a stone. It is in many parts perfectly level; in others undulating, with mounds or hillocks. The towns of Gaza and Ashdod, near the sea, are surrounded by groves of olives, sycamores, and palms. This plain is still, as it always was, a vast corn-field, an ocean of wheat, without a break or fence; its marvellous fertility has produced the same succession of crops, year after year, for forty centuries without artificial aid. The plain of Sharon is about 10 miles wide in the south, narrowing towards the north, till it is terminated by the buttress of Carmel. Its undulating surface is crossed by several streams; the soil is rich, and capable of producing enormous crops; but only a small portion of it near Jaffa is cultivated, and it is rapidly being encroached on by the sea sand, which, between Jaffa and Cesarea, extends to a width of 3 miles and a height of 300 feet. The famous ancient cities of this region, Cesarea, Diospolis, and Antipatris, have vanished. Jaffa (Joppa) alone remains, supported by travellers and pilgrims from the west on the way to Jerusalem. The great plain of Esdraelon, or Jezreel, extends across the centre of the country from the Mediterranean to the Jordan, separating the mountain-ranges of Carmel and Samaria from those of Galilee. Its surface is drained by the Kishon, which flows west to the Mediterranean at Haifa. The plain is surrounded by the hills of Gilboa and Little Hermon; the isolated Mount Tabor rises on its north-east side. It is extremely fertile in grain where cultivated, and covered with gigantic thistles where neglected. It is richest in the

central part, which slopes east to the Jordan—the battle-field where Gideon triumphed, and Saul and Jonathan were overthrown. It is the home of wandering Bedouins, who camp in its fields, and gallop over its green-sward in search of plunder. Many places of deep historical interest are connected with this plain. Shunem, Nain, Endor, Jezreel, Gilboa, Bethshan, Nazareth, and Tabor are all in its vicinity. The plain of Jericho is a vast level expanse, covered with the richest soil, now quite neglected. Around the site of Jericho, 'the city of palm-trees,' there is not now a single palm; but a recent experiment proved its capability of producing in abundance all the crops for which it was formerly famous. The climate of P. is very varied; January is the coldest and July the hottest month. The mean annual temperature of the year at Jerusalem is 65° Fahr., resembling that of Madeira, the Bermudas, and California. The extreme heat of the summer months is modified by sea-breezes from the north-west. In the plain of Jericho and the Jordan valley it is extremely hot and relaxing. The *sirocco*, a south-east wind, is often oppressive in early summer. Snow falls in the uplands in January and February, and thin ice is often found at Jerusalem, where the annual rainfall is 61 inches. Heavy dews fall in summer, and the nights are cold. Violent thunder-storms occur in winter. In the south, Judah and part of Benjamin, is a dry parched land; the bare limestone rock is covered here and there with a scanty soil, and the vast remains of terraces shew how assiduously it must have been cultivated in ancient times to support the teeming population indicated by the ruins of cities with which every eminence is crowned. To the north of Judah the country is more open, the plains are wider, the soil richer, and the produce more varied, till at Nablous the running streams and exuberant vegetation recall to the traveller the scenery of the Tyrol. Even in its desolation, P. is a land flowing with milk and honey. There is no evidence of its climate having changed or deteriorated, nor any reason to suppose that it would fail to support as great a population as ever it did, provided the same means as formerly were used for its cultivation. It has the same bright sun and unclouded sky, as well as the early and latter rain, which, however, is diminished in quantity, owing to the destruction of trees.

The botany of P. is rich and varied, resembling that of Asia Minor. Among its trees are the pine, oak, elder, and hawthorn in the northern and higher districts, and the olive, fig, carob, and sycamore elsewhere. The cultivated fruits are the vine, apple, pear, apricot, quince, plum, orange, lime, banana, almond, and prickly pear. Wheat, barley, peas, potatoes, and European vegetables, cotton, millet, rice, maize, and sugar-cane are among its products. The date now ripens its fruit only in the south and on the sea-board. The brilliant flowers which in spring enamel the surface and tinge the entire landscape, comprise the *adonis*, *ranunculus*, mallow, poppy, pink, anemone, and geranium. In the Jordan valley, 900 or 1000 feet below the sea-level, the vegetation is tropical in its character, resembling that of Arabia; the nubk (*Spina Christi*), the oleander, and the small yellow 'apples of Sodom' are conspicuous. The most valuable products of the vegetable kingdom are derived from the vine, fig, olive, and mulberry trees. Wine for home use is made in all the central and southern districts; the best is made at Hebron from the grapes of *Kahool*. Olive oil is a valuable export.

The wild animals of P. comprise the Syrian bear in Lebanon, the panther, jackal, fox, hyena, wolf, wild boar, gazelle, and fallow-deer; the lion is now unknown. The domestic animals are the Arabian

camel, ass, mule, horse, buffalo, ox, and broad-tailed sheep. Among the birds are the eagle, vulture, kite, owl, nightingale, jay, and kingfisher—the latter of brilliant plumage—the cuckoo, heron, stork, crow, partridge, and sparrow. Fish swarm in the Sea of Galilee, and bats and lizards abound.

The divisions of P. in Old Testament times were into 9½ tribes in the west, and 2½ tribes in the east of the Jordan. In New Testament times, on the west of the Jordan, the provinces of Galilee in the north, Samaria in the middle, and Judea in the south; on the east of the Jordan, Perea and Decapolis. The boundaries of the tribes and provinces are very uncertain. Under Turkish rule, P. is comprised in the vilayet of Syria. The present population, probably not exceeding 700,000, consists mainly of a race of mixed descent, sprung from Syrians, Arabs, and Greeks; they speak Arabic, and are mostly Moslems, some of them nomadic. There are a number of Greek Christians of Syrian descent; a few official Turks, some Maronites, Roman Catholics, and Armenians. The Jews, a few thousands in number, are mostly from Spain and Germany, and are found only in Jerusalem, Hebron, Tiberias, and Safed. A colony of some 750 Germans established themselves some years ago about Carmel and Jaffa. The country is oppressed by Turkish avarice, and overrun by the predatory Arabs. The Palestine exploration societies, English and American, organised in 1865, have done good work in the identification of Biblical and classical sites. See SYRIA.

PALESTRINA, an Italian city 22 miles E.S.E. of Rome, on the slope of an offset of the Apennines. Besides several interesting churches, the town contains a castle, once the chief stronghold of the Colonna, to whom the town belonged; and the palace and garden of the Barberini family. The view across the Campagna and toward the Alban Hills is magnificent. Pop. 6000, who manufacture coarse woollen goods.

P. is built almost entirely upon the site and the gigantic substructions of the Temple of Fortune, one of the great edifices of the former city of Præneste. This city was one of the most ancient as well as powerful and important cities of Latium. It covered the hill (2400 feet above sea-level) on the slope of which the modern town stands, and was overlooked by a citadel of great strength. The site of this citadel on the summit of the hill is now occupied by a castle of the middle ages, called *Castel S. Pietro*; but remains of the ancient walls are still visible. We first hear of Præneste as a member of the Latin League; but in 499 B.C. it quitted the confederacy, and joined the cause of the Romans. In 380 B.C., the Prænestines, having rejoined their ancient allies, opened a war with Rome; but were completely routed on the banks of the Allia by T. Quintius Cincinnatus, and beaten back to their own gates. They took a prominent part in the famous Latin War, 340 B.C. Having given shelter to the younger Marius in the year 82 B.C., this city was besieged by the forces of Sulla, and on its being taken all the inhabitants were put to the sword. A military colony was then established in their place, and soon the city began to flourish anew. Its elevated and healthy situation, at no great distance from the capital, made it a favourite place of resort of the Romans during summer. Augustus frequented it; Horace often found this city a pleasant retreat; and here Hadrian built an extensive villa. The Temple of Fortune is described by Cicero as an edifice of great antiquity as well as splendour, and its oracle was much consulted. The town became the stronghold of the family of Colonna in the middle ages; but was given to the Barberini family by Urban VIII.

PALESTRINA, GIOVANNI PIERLUIGI DA, a distinguished musical composer of the 16th century. He derived his surname from the town of Palestrina, in the Roman States, where he was born in 1524. At the age of sixteen, he went to Rome, and studied music under Claude Goudimel, afterwards one of the victims of the St Bartholomew massacre. In 1551 he was made *maestro di capella* of the Julian Chapel, and in 1554 he published a collection of Masses, so highly approved of by Pope Julius III., to whom they were dedicated, that he appointed their author one of the singers of the pontifical chapel. Being a married man, he lost that office on the accession to the pontificate of Paul IV., in whose eyes celibacy was a necessary qualification for its duties. In 1555 he was made choir-master of St Maria Maggiore, and held that position till 1571, when he was restored to his office at St Peter's. In 1563, the council of Trent having undertaken to reform the music of the church, and condemned the profane words and music introduced into masses, some compositions of P. were pointed to as models, and their author was intrusted with the task of remodelling this part of religious worship. He composed three masses on the reformed plan; one of them, known as the Mass of Pope Marcellus (to whose memory it is dedicated), may be considered to have saved music to the church by establishing a type infinitely beyond anything that had preceded it, and, amid all the changes which music has since gone through, continues to attract admiration. During the remaining years of his life, the number and the quality of the works of P. are equally remarkable. His published works consist of 13 books of Masses, 6 books of Motets, 1 book of Lamentations, 1 book of Hymns, 1 book of Offer-tories, 1 book of Magnificats, 1 book of Litanies, 1 book of Spiritual Madrigals, and 3 books of Madrigals. P. must be considered the first musician who reconciled musical science with musical art, and his works form a most important epoch in the history of music. Equally estimable in private life, and talented as a musician, P. struggled through a life of poverty during eight pontificates; his appointments were meagre, and his publications unremunerative. He died in 1594. A memoir of his life and writings has been written by the Abbé Baini.

PALESTRO, a village of Piedmont, 8 miles south-east of Vercelli, famous as the scene of a battle between the Sardinians and Austrians in May 1859. On the 30th of that month the Piedmontese drove the Austrians from this village, and on the 31st defended it with great bravery against an Austrian attack. The Piedmontese in the battle of the 31st were assisted by 3000 French Zouaves, and on that occasion the Austrians lost 2100 men killed and wounded, 950 prisoners, and 6 pieces of cannon. On June 1st the allies entered Novara.

PALETTE. See PAINTING.

PALEY, DR WILLIAM, a celebrated English divine, was born at Peterborough in 1743. His father was a Yorkshireman, and not long after P. was born returned to his native parish of Giggleswick, one of the wildest and most sequestered districts in the West Riding, to become master of the grammar-school there. Young P. was brought up among the shrewd, hard-headed peasantry of Yorkshire; and it is probable that he either naturally possessed, or insensibly acquired their moral and mental characteristics. At all events, he soon became conspicuous in the family for his good sense; and when he left to enter Christ's College, Cambridge, as a sizar, in his sixteenth year, his father said: 'He has by far the clearest head I ever met with.' At Cambridge, P. led for the first

two years a gay, idle, and dissipated life, but thereafter became a severe student, and took his bachelor degree in 1763 with highest honours. He then taught for three years in an academy at Greenwich. In 1765 he obtained the first prize for a prose Latin dissertation—the subject being 'A Comparison between the Stoic and Epicurean Philosophy with respect to the Influence of each on the Morals of a People,' in which he characteristically argued in favour of the latter. Next year he was elected a Fellow and Tutor of Christ's, and also took the degree of M.A. In 1767 he was ordained a priest. His career as a college tutor, which lasted about ten years, was eminently successful; and it appears to have been during this period that he systematised his principles in moral and political philosophy. In 1776, P. married, and was of course obliged to give up his fellowship, but was compensated by a presentation to the livings of Mosgrove and Appleby in Westmoreland and of Dalston in Cumberland. Four years later he was collated to a prebendal stall in the cathedral church of Carlisle, in 1782 he became archdeacon, and in 1785 chancellor of the diocese. The last of these years witnessed the publication of his *Elements of Moral and Political Philosophy*. In this work he propounds his ethical theory, which is commonly called utilitarianism, but is really a mixture of utility and theology. He begins by renouncing the favourite doctrine of the Moral Sense, against which he adduces a series of strong objections. He then takes up the question of the source of obligation, and resolves it into the will of God, enforced by future punishment, admitting candidly that virtue is prudence directed to the next world. The will of God, in so far as it is not rendered explicit by revelation, is to be interpreted by the tendency of actions to promote human happiness; the benevolence of the Deity being supposed. Objection has frequently been taken to the principles on which P. rests his system, but the lucidity and appositeness of his illustrations are beyond all praise. If his treatise cannot be regarded as a profoundly philosophical work, it is at anyrate one of the clearest and most sensible ever written, even by an Englishman; and if it failed to sound the depths of 'moral obligation,' it at least brushed off into oblivion the shallow and muddy mysticism that had long enveloped the philosophy of politics. P.'s plain sarcastic view of the 'divine right of kings,' which he puts on a level with the 'divine right of constables,' gave extreme offence to George III., but was nevertheless much admired by not a few of his majesty's subjects, and is now held by everybody to be beyond question. In 1790 appeared his most original and valuable work—the *Hours Paulina, or the Truth of the Scripture History of St Paul evinced by a Comparison of the Epistles which bear his Name with the Acts of the Apostles, and with one another*. The aim of this admirable work is to prove, by a great variety of 'undesigned coincidences,' the improbability, if not impossibility, of the usual infidel hypothesis of his time—viz., that the New Testament is a 'cunningly-devised fable.' It was dedicated to his friend John Law, then Bishop of Killala in Ireland, to whose favour he had been indebted for most of his preferments. P.'s next important work was entitled *A View of the Evidences of Christianity*, published in 1794. It is not equal in originality to its predecessor, but the use which the author has made of the labours of such eminent scholars as Lardner and Bishop Douglas is generally reckoned most dexterous and effective. Later and keener criticism is indeed anything but satisfied with P.'s 'Evidences;' but in P.'s own day he was held to have achieved a splendid triumph over

sceptics, and was handsomely rewarded. The Bishop of London appointed him a prebend of St Pancras; shortly after he was promoted to the subdeanery of Lincoln (worth £700 per annum); Cambridge conferred on him the degree of D.D.; and the Bishop of Durham the rich rectory of Bishop Wearmouth (worth £1200 per annum), in consequence of which he honourably resigned his livings in the diocese of Carlisle. After 1800 he became subject to a painful disease of the kidneys, but notwithstanding he continued to write, and in 1802 published perhaps the most widely popular of all his works, *Natural Theology, or Evidences of the Existence and Attributes of the Deity*, which, however, is based, and to a large extent borrowed from the *Religious Philosopher*, the work of a Dutch philosopher named Nieuwentijt, an English translation of which appeared in 1718—1719. The plagiarisms are most palpable, but have been accounted for on the supposition that the *Natural Theology* was 'made up' from his loose papers and notes written when P. was a college tutor, and that he had forgotten the sources from which he derived them. It is also but fair to state that he has taken nothing which he has not greatly improved; *nihil tetigit, quod non ornavit*. A somewhat noted edition of this work, enriched, or at least expanded by annotations and dissertations, is that by Lord Brougham and Sir Charles Bell (1836—1839). P. died May 25, 1805. He had a family of four sons and three daughters. A complete edition of his works was published in 1838 by one of his sons, the Rev. Edmund Paley. The best biography is that by Meadley (1809).

PALGRAVE, SIR FRANCIS, a distinguished antiquary and historian, was born in London in July 1788, of Jewish parentage, being the son of Mr Meyer Cohen, a member of the Stock Exchange. He was educated at home under a Dr Montucci, and even when a child shewed extraordinary genius. When only eight years old, he made a translation into French of the *Battle of the Frogs and Mice* from the Latin version of Beauclerc, which was printed by his father in 1797. In 1803 he was articled as a clerk to a legal firm, and at the expiration of his articles, continued with the same firm as managing clerk until 1822, when he took chambers in the Temple, and was employed under the Record Commission. He had previously made himself known as a literary antiquarian, by the publication, in 1818, of some Anglo-Norman Chansons, which he edited with much care. On the occasion of his marriage in 1823, he changed his name of Cohen to P., that being the maiden name of his wife's mother. He was called to the bar in 1827, and had considerable practice for some years in pedigree cases before the House of Lords. In 1831 he published a *History of England*, which formed a part of the *Family Library*; and in 1832 appeared his *Rise and Progress of the English Commonwealth*; also *Observations on the Principles, &c., of New Municipal Corporations*. In that year he received the honour of knighthood, and was subsequently one of the Municipal Corporation Commissioners. In 1835, the Commissioners issued their Report, which was signed, however, by only sixteen of the members—Sir F. P. being one of the four dissentients. In the same year he published a 'Protest' against the Commissioners' Report, in which he called in question several of its statements, views, and arguments. In 1838, on the reconstruction of the Record Service, Sir F. P. was appointed deputy-keeper of Her Majesty's Records, and held that office during the rest of his life. Besides the works already mentioned, Sir F. P. edited for the government the following: *Calendars of the Treasury of the Exchequer, Parliamentary*

Writs, Curia Regis Records, and Documents Illustrative of the History of Scotland. In his private capacity, he produced the *Merchant and the Friar*, an imaginary history of Marco Polo and Friar Bacon; also a *Hand-book for Travellers in Northern Italy*, and a *History of England and Normandy*. Of this last work a volume appeared in 1851, and a second in 1857; and the third and fourth volumes were published within three years after their author's death. Sir F. P. also wrote numerous articles for the *Edinburgh* and *Quarterly Reviews*, principally of an antiquarian character, but some of them purely literary or artistic. His great merit, in his historic writings, consists in the extensive use made by him of original documents, by aid of which he not only himself very much enlarged our acquaintance with the history and social aspects of the middle ages, but pointed out to others the advantage to be derived from a careful study of the original sources of information now known to abound among our public records. Sir F. P. died at Hampstead, on the 6th of July 1861.

PĀLI (a corruption of the Sanscrit *Prākṛit*, q. v.) is the name of the sacred language of the Buddhists. Its origin must be sought for in one or several of the popular dialects of ancient India, which are comprised under the general name of *Prākṛit*, and stand in a similar relation to Sanscrit as the Romance languages, in their earlier period, to Latin. It has been formerly assumed that P. arose from the special *Prākṛit* dialect called *Māgadhi*, or the language spoken in *Magadha*; but, according to the view expressed by Lassen in his *Indische Alterthumskunde*, an hypothesis of this kind is not tenable, since the peculiarities of this dialect are not compatible with those of the P. language. The same distinguished scholar holds that the *Prākṛit* dialects, called the *Sauraseni* and *Māhārāṣṭrī*, have a closer relation to the P. than any other, and that the origin of the latter must therefore be traced to the country of Western Hindustan, between the *Jumna* river and the *Vindhya* mountain; though he observes, at the same time, that the P. is older than these dialects, and that the latter are therefore more remote from Sanscrit than the former. Whether the oldest works of the Buddhist religion were written in P. may be matter of doubt. It is more probable, on the contrary, that the language in which the founder of the Buddhist religion conveyed his doctrine to the people was not yet that special language, but a mixture of classical and popular Sanscrit, such as it still appears in the Buddhist *Sūtras*. At a later period, however, P. became the classical language in which the Buddhists wrote their sacred, metaphysical, and profane works. The most important historical work written in this language is the *Mahāvamsa* (q. v.); other P. works, which have lately become known in Europe, and deserve especial mention, are the *Dhammapada*, on the Buddhist doctrine, and five *Jātakas*, containing a fairy tale, a comical story, and three fables—both works edited and translated by V. Fausbøll (Copen. 1855 and 1861). P. ceased to be a living language of India when Buddhism was rooted out of it; it was carried by the fugitive Buddhists to other countries, especially Ceylon, Burmah, and Siam; but in these countries, too, it had to give way before the native tongues, in which the later Buddhist literature was composed.

PA'LIMPSEST (Gr. *palimpsestos*, 'rubbed a second time'), the name given to parchment, papyrus, or other writing material, from which, after it had been written upon, the first writing was wholly or in part removed for the purpose of the page being

written upon a second time. When the MS. had been written with one species of ink employed by the ancients, which was merely a fatty pigment, composed chiefly of lampblack, and only colouring the surface, but not producing a chemical change, there was little difficulty in obliterating the writing. It was accomplished by the use of a sponge, and, if necessary, of a scraper and polishing tool; and, where proper pains were taken, the erasure of the first writing was complete. But when the ink was mineral, its effect reached beyond the surface. In that case a scraping-tool or pumice-stone was indispensable; if these were hastily or insufficiently applied, the erasure was necessarily imperfect; and thus it often happens in ancient MSS. that, from the want of proper care on the part of the copyist in preparing the parchment for re-writing, the original writing may still be read without the slightest difficulty.

The practice of re-preparing used parchment for second use existed among the Romans. The material thus re-prepared was of course reserved for the meaner uses. We meet frequent allusions in the classical writers, as Plutarch, Cicero (*Ad Familiares*, vii. 18), Catullus (xxii. 115), and others, to the palimpsest, in the sense of a blotter or first draft-book, on which the rough outline or first copy of a document was written, preparatory to the accurate transcript which was intended for actual use; and it appears equally certain that in many cases whole books were written upon re-prepared parchment or papyrus, not only among the Greeks and Romans, but also among the ancient Egyptians.

Of palimpsests of the classic period, however, it is hardly necessary to say no specimen has ever been discovered. It is to the necessities of the medieval period that literature owes the unquestionably important advantages which have arisen from the revival of the ancient practice of re-preparing already used material for writing. Under the early emperors, the intercourse with Egypt and the east secured a tolerably cheap and abundant supply of Papyrus (q. v.), which rendered it unnecessary to recur to the expedient of the palimpsest; and this became still more the case in the 5th and 6th centuries, when the tax on papyrus was abolished. But

after the separation of east and west, and still more after the Mohammedan conquest of Egypt, the supply of papyrus almost completely ceased; and from the 7th c. in the west, and the 10th or 11th in the east, the palimpsest is found in comparatively frequent use; and its frequency in the 15th c. may be estimated from the fact that some of the earliest books were printed on palimpsest. Some writers have ascribed the prevalence of its use to the indifference, and even to the hostility of the monks and clergy to classical literature, and have attributed to their reckless destruction of classic MSS., in order to provide material for their own service-books and legendaries, the deficiencies in the remains of ancient learning which scholars have now to deplore. That some part of the loss may have so arisen, it is impossible to doubt, although it is equally certain that we owe to the medieval monks and clergy whatever of ancient literature has been preserved to our day. But the condition in which the existing palimpsests are uniformly found—for the most part mere fragments of the ancient writers whose works they originally contained—goes far in itself to shew that the MSS. which were broken up by the medieval copyists, for the purpose of being re-written, were almost always already imperfect, or otherwise damaged; nor is there anything in the condition of any single palimpsest which has reached our day to justify the belief, that when it was taken up for the purpose of rescription, the original work which it contained was in a state at all approaching to completeness. Fortunately, however, there are many of the relics of ancient learning of which even the mutilated members have an independent value; and this is especially true of Biblical MSS., particularly under the critical aspect, and in a still broader sense, of all the remains of the ancient historians.

It will easily be understood, therefore, that the chief, if not the sole interest of palimpsest MSS. lies in the ancient writing which they had contained, and that their value to literature mainly depends on the degree of legibility which the ancient writing still retains. It is difficult to make this fully intelligible to the reader without an actual inspection, but the facsimile which is annexed will furnish a sufficient idea. The particular passage

boengest quia
et omnes xpiani membra sunt xpi
membra xpi quid cantant. Amant
desiderando cantant. Aliquando

selected for the illustration is from page 62 of the Vatican MS., from which Mai deciphered the fragments of the *De Republica*. The darker letters are those of the modern MS.; the faint lines are, as may be supposed, those of the original codex. Although so much more faint than the modern writing, they can be read with facility on account of their greater size. We shall transcribe both texts in ordinary characters. The original was as follows:

EST
IGNITUR INQUIT
AFRICANUS RESP.

(The ordinary contraction for *Respublica*.)

The corresponding lines of the modern MS., which

is from St Augustine's commentary on the Psalms, are—

homo est quia
et omnes xpiani (Christiani) membra sunt xpi. (Christi)
membra xpi. quid cantant. Amant
Desiderando cantant. Aliquando

In this specimen, as very commonly occurs, the original writing is much larger than the modern; the modern lines and letters do not cover those of the old MS., but they follow the same order. In other specimens the new writing is transverse; in some, the old page is turned upside down. Sometimes, where the old page is divided into columns, the new writing is carried over them all in a single

line; sometimes the old page is doubled, so as to form two pages in the new MS. Sometimes it is cut into two, or even three pages. The most perplexing case of all for the decipherer is that in which the new letters are of the same size, and are written upon the same lines with those of the original MS. Examples of this are rare, and even when they occur, the difference between the form of the ancient characters, which are ordinarily uncial, and that of the modern, is in itself a great aid to the decipherer. Some variety, also, is found in the language of the palimpsests. In those which are found in the western libraries, the new writing is almost invariably Latin, while the original is sometimes Greek, and sometimes Latin. In the palimpsests discovered in the east, the original is commonly Greek, the new writing being sometimes Greek, sometimes Syriac, sometimes Armenian; and one palimpsest, the material of which is papyrus, is found in which the original was the enchorial Egyptian language, while the modern writing is Greek.

The possibility of turning palimpsest MSS. to account as a means of extending our store of ancient literature, was suggested as far back as the days of Montfaucon; but the idea was not turned to practical account till the latter part of the 18th century. The first palimpsest editor was a German scholar, Dr Paul Bruns, who having discovered that one of the Vatican MSS. was a palimpsest, the effaced matter of which was a fragment of the 91st book of Livy's *Roman History*, printed it at Hamburg in 1773. In the field of discovery thus opened by Bruns but little progress was made until the following c., when Dr Barrett of Trinity College, Dublin, published his palimpsest *Fragment of St Matthew*, and when palimpsest literature at once rose into interest and importance in the hands of the celebrated Angelo Mai (q.v.). A detailed account of Mai's successes will be given hereafter, when we shall enumerate the principal publications in this curious department of letters; and under his own name will be found the history of his personal labours. The great historian Niebuhr about the same time applied himself to the subject, and was followed by Blume, Pertz, Gaupp, and other German scholars, whose labours, however, were for the most part confined to the department of ancient Roman law. More recently, the discoveries of Dr Tischendorf in Biblical literature, and those of Dr Cureton as well in sacred as in profane literature, have contributed still more to add importance to the palimpsest MSS. which have been supposed to exist in the monasteries of the Levant. Herr Mone has had similar success in the department of liturgical literature, and Dr Frederick Augustus Pertz, son of the scholar already mentioned, may be said to have carried to its highest point the interest which attaches to these curious researches, by editing from a *thrice written palimpsest* a very considerable series of fragments of the Roman annalist, Gaius Granius Licinianus.

It remains to enumerate briefly the most important palimpsest publications which have hitherto appeared, distributed according to the language of the effaced original.

I. GREEK PALIMPSESTS.—Among these, the first place of course belongs to the Greek Biblical palimpsests, the earliest of which was (1) *Fragment of the Gospel of St Matthew*, in facsimile as well as in ordinary type, printed from a palimpsest MS. of Trinity College, Dublin, by the Rev. I. Barrett, D.D. (4to, Dublin, 1801). The original writing appears to be of the 6th century. Dr Barrett's transcript of the text has not proved in all respects correct, but the original has since been carefully re-examined, and

the ancient writing fully brought out. It is chiefly, however, to a collection of Syriac MSS. brought from the east that we are indebted for the more recent palimpsest restorations of the ancient Biblical readings. In this line the chief discoverer has been Dr Constantine Tischendorf. From his pen we have (2) the celebrated *Codex Ephremi* or *Codex Regius* of the Royal Library at Paris. This MS. had been early observed to be palimpsest, and the original Greek text was collated in part by Wetstein and by Küster. It was still more carefully examined by M. Hase in 1836; and finally, in 1840, by Dr Tischendorf, by whom the New Testament was printed in 1843, and the fragments of the Old in 1845. The modern writing of this palimpsest consisted of the works of St Ephrem the Syrian. (3) *Fragmenta Sacra Palimpsesta* (4to, Leipzig, 1855), containing fragments of the Books of Numbers, Deuteronomy, Joshua, Judges, Kings, Isaiah, together with 48 pages of fragments of the New Testament, the Gospels, the Acts, and the Epistles of St Paul to the Corinthians and to Titus. The modern writing of these palimpsests was partly Greek, partly Armenian, and Arabic. (4) *Fragmenta Evangelii Lucae et Libri Genesis* (4to, Leipzig, 1857). The fragments of St Luke's Gospel amount to 95 pages. The volume also contains fragments of St John's Gospel and of Ezekiel and the Third Book of Kings. The modern writing is partly Syriac, partly Coptic. Along with these Biblical palimpsests (5) may be classed another, the original of which, however, contains not only some Greek fragments, but also portions of the ancient Gothic version of the Bible by Ulphilas. The MS. from which this is taken is known from its place in the Wolfenbüttel Library as the *Codex Guelpherbytanus*. It was first noticed in 1755 by Knittel, by whom a portion of the Gothic version was published in 1762. These fragments were reprinted in 1772, and again in 1805. The modern writing of the MS. consisted of the *Origines* of Isidorus Hispalensis. A large addition to the text of Ulphilas was made in 1817 by Mai and Castiglione, from palimpsests discovered in the Ambrosian Library at Milan; and the whole have since been combined into one edition by Dr Gabelentz, and finally by Dr Maassmann (4to, Stuttgart, 1855). We may also mention under the same head some interesting Greek liturgical remains edited by F. L. Mone (Frankfurt, 1850), from a palimpsest discovered at Carlsruhe.

In Greek classical literature, also, we owe something to the labours of palimpsest editors. From one of the Syriac MSS. already referred to, Dr Cureton has edited large fragments of the *Iliad* of Homer, amounting in all to nearly 4000 lines; and although all these, it need hardly be said, were known before, yet the text is of the utmost value as a source of criticism, being certainly of much greater antiquity than the very earliest known MSS. of the *Iliad*. A still larger and more original contribution to Greek classical literature was made by Mai in the 5th volume of his *Scriptorum Veterum Nova Collectio* (Rome, 1831—1838). From a very large palimpsest discovered in the Vatican Library he has printed in this volume copious fragments of almost all the Greek writers on Roman history—from the lost books of Polybius no less than 100 4to pages; 130 pages of Diodorus Siculus; 64 of Dionysius of Halicarnassus; 100 of Dion Cassius; together with considerable fragments of Appian, Iamblichus, Dexippus, Eusebius, and others. This is, perhaps, after the *De Republica* of Cicero, the most important accession to the existing store of classic learning which the palimpsests have hitherto supplied.

II. LATIN PALIMPSESTS.—(1.) The earliest frag-

ment of Latin literature, printed from a palimpsest original, is the portion of the 91st book of *Livy* already referred to, published at Hamburg and also at Rome in 1773. It was re-edited in a more complete form by Niebuhr in 1820. (2) Of the Latin palimpsests edited by Mai, the earliest were some fragments of lost Orations of Cicero from two different palimpsests in the Ambrosian Library at Milan, in the latter of which, the second writing consisted of the acts of the council of Chalcedon. These Orations were published in two successive volumes in 1814. (3) Eight Orations of Symmachus (1815). (4) The Comedies of Plautus, including a fragment of the lost play entitled *Vidularia* (1815). (5) The works of M. Corn. Fronto, together with the Epistles of Antoninus Pius, Lucius Verus, M. Aurelius, and others (1815). (6) The celebrated Dialogue of Cicero, *De Republica*, from a palimpsest of the Vatican, the modern writing of which is the commentary of St Augustine on the Psalms. There is none of Mai's publications which presents his critical abilities in so favourable a light as this precious volume, which appeared at Rome in 1821. (7) Soon after the *De Republica* he published another volume from palimpsest sources, the most important of whose contents were some fragments of ancient Roman law, which prepared the way for the more distinguished success of Niebuhr; who, in a palimpsest of the library of Verona, recognised a portion of (8) the *Institutiones* of Gaius, and procured an accurate transcript for the press, which was printed at Berlin in 1820. The latest considerable Latin publication in this department is (9) *Gaii Gracii Liciniani Annalium quæ supersunt* (Berlin, 1857), edited from a palimpsest of the British Museum by the younger Pertz. This palimpsest, as was already stated, is a thrice written codex, the earliest and original contents being the *Annales* of Gaius Gracianus. The second writing was also in Latin, and the work is a grammatical treatise, of which the chapters *De Verbo* and *De Adverbio* are still legible. The most modern writing is Syriac, written in the cursive character. Gaius Gracianus is a writer named by Macrobius, of whom nothing else is known.

It will be gathered from the above that the ancient works recovered by means of palimpsest MSS. are all fragmentary, and one is naturally led to rate at a low value the result thereby obtained. But it must be remembered that in some of the departments to which these fragments belong, every scrap, no matter how trifling, has an independent value. So it is, for example, in Biblical remains—a single text may present a valuable reading, the merest fragment may throw light on an important critical question. In history, in like manner, a small fragment may disclose an interesting fact, or supply a significant commentary upon facts otherwise ascertained. And as regards critical uses especially, it must not be forgotten that the obliterated text of the palimpsest MSS. for the most part, far exceeds in antiquity the very oldest known codices which we possess, and is, probably, second only in age to the papyri of Herculaneum.

The method of treating palimpsest MSS., with a view to deciphering their contents, has been fully described by different editors. Mai, after having washed the palimpsest with an infusion of galls, exposed it to the light and air, and, generally speaking, found this sufficient for his purpose. Peyron washed the parchment in water, afterwards in dilute muriatic acid, and finally in prussiate of potash. A mixture, compounded on this principle, is called from its inventor, M. Gioberti, *Tinctura Giobertina*. Sometimes the same treatment does not succeed equally well on both sides of the parch-

ment; the inner surface, from its softer texture, sometimes requiring a more active preparation. When the ink contained animal substances, as milk, or the blood of the cuttle-fish, Dr Mone plunged the parchment in a close vessel filled with oil, which he heated to a temperature of 400° R. In the prefaces of Mai's volumes will be found many amusing and interesting facts illustrating the difficulties which attend this curious branch of literary labour.

PALINDROME (Gr. *palin*, backwards, and *dromos*, a running), the name given to a kind of verse very common in Latin, the peculiarity of which is that it may be read the same backwards as forwards. A few examples will suffice.

*Si bene te tua laus laetatur tua laetatur tenebris.
Et necat eger amor non Roma rege tacente,
Roma reges una non anus eger amor.*

A Roman lawyer gets the credit of the following:

Si nummi immuni,

which Camden translates:

'Give me my fee, and I warrant you free.'

It is said that in the reign of Queen Elizabeth a certain lady of rank, having been compelled to retire from the court on account of some *fama*, the truth of which she denied, took for her motto:

*Ablata at alba.
'Retired but pure.'*

The English language has few palindromes, but one at least is inimitable. It represents our first parent politely introducing himself to Eve in these words:

'Madam, I'm Adam.'

Compare Henry B. Wheatley's book on *Anagrams* (1862).

PALINGENE'SIA (Gr. *palin*, again, and *genesis*, birth) is a term that appears to have originated among the Stoics, who employed it to denote the act of the Demiurgus, or Creator, by which, having absorbed all being into himself, he reproduced it in a new creation. The occurrence of the word in the New Testament (Titus, iii. 5, where it is used to denote regeneration) has given it a place in Christian theology, and divines have variously used it to express the resurrection of men, the new birth of the individual soul, and the restoration of the world to that perfect state that it lost by the Fall—'the new heavens and the new earth wherein dwelleth righteousness.' Savans have also applied the term to designate both the great geological changes which the earth has undergone and the transformations in the insect kingdom, such as of caterpillars into butterflies, &c.

PALINODE, in the law of Scotland, is a peculiar practice by which, in actions for damages on account of slander or defamation raised in the Commissary Court, and even in the Sheriff Court, the pursuer may conclude not only for damages but for palinode, i.e., a solemn recantation. On a recent case, the question arose whether this ancient practice still existed as part of the law of Scotland, and it was held that it did. In actions, however, in the Court of Session, damages only are given as the remedy.

PALISADE, a paling of strong timber, used in Fortification. For the mode in which the palisade is employed see **FORTIFICATION**, under the head *Stockade*.

PALISANDER WOOD, the continental name for Rosewood (q. v.). By some of the French cabinet-makers the name *bois de Palisandre* is also

applied to violet wood and to a kind of striped ebony.

PALISSY, BERNARD, a French potter, famous for his glass paintings and beautiful figured pottery, was born near Agen, now in the department of Lot et Garonne, France, about 1510, and at an early age was apprenticed to a potter. He devoted himself to chemical researches for the improvement of his art, and made many journeys through France and Germany for the same purpose; at the same time carrying on the business of a land-surveyor. An enamelled cup of 'Faience,' which he saw by chance, inspired him with the resolution to discover the mode of producing white enamel. Neglecting all other labours, he devoted himself to investigations and experiments for the long period of 16 years. He had by this time exhausted all his resources, and for want of money to buy fuel was reduced to the necessity of burning his household furniture piece by piece; his neighbours laughed at him, his wife overwhelmed him with reproaches, and his starving family surrounded him crying for food; but in spite of all these discouragements he persisted in the search, and was in the end rewarded by success. A few vessels adorned with figures of animals, coloured to represent nature, sold for high prices, and enabled him to complete his investigations, after which he became famous; and though a Huguenot, was protected and encouraged by the king and the nobility, who employed him to embellish their mansions with specimens of his art. He was lodged in or near the Tuileries, and was specially exempted by Queen Catharine from the massacre of St Bartholomew, more from a regard to her own benefit than from kindness. In March 1575 he commenced a course of lectures on natural history and physics, and was the first in France to substitute positive facts and rigorous demonstrations for the fanciful interpretations of philosophers. In the course of these lectures, he gave (1594) the first right notions of the origin of springs, and the formation of stones and fossil shells, and strongly advocated the importance of marl as a fertilising agent. These, along with his theories regarding the best means of purifying water, have been fully supported by recent discovery and investigation. In 1588 he was arrested and thrown into the Bastille as a heretic, but died in 1590 before his sentence was pronounced.

P. left a collection of objects of natural history, the first that had been formed in France. His works are at the present day almost beyond price, and his ornaments and arabesques are amongst the most beautiful of the 'renaissance.' As a sincere, earnest, and courageous man, he was no less eminent than as an artist. See Morley's *Palissy the Potter*.

PALIU'RUS, a genus of trees and shrubs of the natural order *Rhamnaceæ*, nearly allied to *Zizyphus* (see *JUJUBE*), but very different in the fruit, which is dry, orbicular, and girded with a broad membranous wing. *P. aculeatus* is often called **CHRIST'S THORN**, and by the Germans, **JEW'S THORN** (*Juden-dorn*), from an imagination that it supplied the crown of thorns with which our Saviour was crowned. It is a deciduous shrub or low tree, with slender, pliant branches and ovate 3-nerved leaves, each of which has two sharp spines at the base, one straight and the other re-curved. It is a native of the countries around the Mediterranean, of India, and many parts of Asia. It is often used for hedges in Italy and other countries; its sharp spines and pliant branches admirably adapting it for this purpose. The fruit has a singular appearance, being flat and thin, attached by the middle to the foot-stalk, the middle being raised like the crown of a hat, whilst the expansion resembles the brim. The

seeds are sold by the druggists of the east, and are used medicinally, but their qualities are doubtful.

Christ's Thorn (*Paliurus aculeatus*):
a, ripe fruit.

This shrub is not uncommon in shrubberies in England, being very ornamental when in flower, but the fruit does not ripen.

PALK STRAIT, or **PALK'S PASSAGE**, the northern portion of the passage between the south coast of Hindustan and the island of Ceylon. This passage is continued southward by the Gulf of Manaar (q. v.). It is from 40 to 80 miles in width, and is 80 miles in length. It is so shallow—in some places being no more than two fathoms in depth—that it cannot be navigated in safety by large vessels. In P. S. there are several pearl fisheries.

PALL (Lat. *pallium*, also *palla*, a cloak), the name given in English to two very different portions of the vesture employed in the religious use of the Roman and some other churches. One of these is the *funeral pall*, an ample covering of black velvet or other stuff, which is cast over the coffin while being borne to burial. The ends of the pall are held during the funeral procession by the most distinguished among the friends of the deceased, generally selected from among those unconnected by blood. In its second and most strictly liturgical use, the word pall is applied to one of the coverings used at the altar in the celebration of the mass. Primitively, as appears from Optatus and other early writers, the altar was covered with a large linen cloth—called by the Latins *pallium*, and by the Greeks *eileton*—the extremities of which were folded back so as to cover the bread and wine prepared for the celebration of the eucharist. In later times a separate covering was employed for the sacramental chalice, to which latter the name pall is now reserved in the use of the Roman Church. The modern Roman pall is a square piece of linen cloth—sometimes limber, sometimes made stiff by inserting pasteboard—sufficiently large to cover the mouth of the chalice. The upper surface is often of silk embroidered, or of cloth of gold. The surface in contact with the chalice must always be of linen.

PALL, in Heraldry, the upper part of a saltire conjoined to the lower part of a pale. It appears much in the arms of ecclesiastical sees.

PALL-MALL. See MALL.

PALLADIO, ANDREA, a famous Italian architect, was born at Vicenza, 30th November 1518. After having studied with the greatest care the writings of Vitruvius, and the monuments of antiquity at Rome, he settled in his native city, and first acquired a reputation by his restoration of the Basilica of Vicenza. Pope Paul III. then invited him to Rome, designing to intrust him with the execution of the works then going on at St Peter's, but his holiness dying before the arrival of P., the latter had to return home. He was employed for many years in the construction of numerous buildings in Vicenza and the neighbourhood, in all of which he displayed the most exquisite taste combined with the most ingenious and imaginative ornamentation. His style, known as the Palladian, is a composite, and is characterised by great splendour of execution and justness of proportion, and it exercised an immense influence on the architecture of Northern Italy. His principal works are the Rotonda Capra, outside Vicenza; the Palazzo Chiericaco and the Palazzo Tiene, in the city; the Palazzo Barbara, at Maser in the Trevigiano, the Teatro Olympico at Vicenza (his last work), the Palazzo at Montagnana for Francesco Pisana; the churches of San Giorgio Maggiore and Il Santissimo Redemptore at Venice, the atrium and cloister at the convent Della Carità, and the façade of San Francesco della Vigna in the same city. P. died at Vicenza, August 6, 1580. He wrote a work on architecture, which is highly prized. The best edition is that published at Vicenza in 4 vols., 1776.

PALLADIUM (symb. Pd, eq. 53—new system, 106—spe. grav. 11·8) is one of the so-called noble metals, which in its colour and ductility closely resembles platinum. It is not fusible in an ordinary wind-furnace, but melts at a somewhat lower temperature than the last-named metal; and when heated beyond its fusing-point, it volatilises in the form of a green vapour. It undergoes no change in the open air at ordinary temperatures; but at a low red heat, it becomes covered with a purple film, owing to superficial oxidation. It is soluble in nitric and iodic acids, and in aqua regia. It combines readily with gold, which it has the property of rendering brittle and white. (When it forms 20 per cent. of the mass, the alloy is perfectly white.) When alloyed with twice its weight of silver, it forms a ductile compound, which has been employed for the construction of small weights; but for this purpose aluminium is superior. Professor Miller states that it 'has been applied in a few cases to the construction of graduated scales for astronomical instruments, for which, by its whiteness, hardness, and unalterability in the air, it is well adapted; its scarcity must, however, prevent its general use for this purpose.

It was discovered in 1803 by Wollaston in the ore of platinum, of which it seldom forms so much as 1 per cent. Another source of this metal is the native alloy which it forms with gold in certain mines in Brazil, and which is termed *ouro poudre*; and it is from this alloy that the metal is chiefly obtained.

Palladium forms with oxygen a protoxide, PdO, which is the base of the salts of the metal; a binoxide, PdO₂; and according to some chemists, a suboxide, Pd₂O. On exposure to sufficient heat, these compounds give off their oxygen, and yield the metal. The salts of the protoxide are of a brown or red colour.

PALLADIUM, among the ancient Greeks and Romans, an image of Pallas, who was generally identified with Athene, upon the careful keeping of which in a sanctuary the public welfare was believed

to depend. The Palladium of Troy is particularly celebrated. According to the current myth, it was thrown down from heaven by Zeus, and fell on the plain of Troy, where it was picked up by Ilus, the founder of that city, as a favourable omen. In the course of time, the belief spread that the loss of it would be followed by the fall of the city; it was therefore stolen by Odysseus and Diomedes. Several cities afterwards boasted of possessing it, particularly Argos and Athens. Other accounts, however, affirm that it was not stolen by the Greek chiefs, but carried to Italy by Æneas; and the Romans said that it was preserved in the temple of Vesta, but so secretly, that even the Pontifex Maximus might not behold it. All images of this name were somewhat coarsely hewn out of wood.

PALLADIUS, RUTILIUS TAURUS ÆMILIANUS, a Roman author, who probably lived in the 4th c. A.D., under Valentinian and Theodosius. He wrote a work, *De Re Rustica* (On Agriculture), in 14 books, the last of which is a poem of 85 elegiac couplets. It is, from a literary and grammatical point of view, full of faults; but as it was a complete calendar of Roman agriculture, it was very useful for its time, and was much read and followed during the middle ages. P. has borrowed largely from his predecessors. The best edition is that by J. G. Schneider in his *Scriptores Rei Rusticæ Veteris Latini* (4 vols., Leip. 1794).

PALLAS. See MINERVA.

PALLAS, PETER SIMON, an eminent traveller and naturalist, was born, 22d September 1741, at Berlin, where his father was a physician. He studied medicine, natural history, and other branches of science, at the universities of Berlin, Göttingen, and Leyden, and was employed in classifying many valuable collections of objects of natural history, both in Holland and England. He gained a high reputation by the publication of his *Blenschus Zoophytorum* (Hague, 1766), a work still much valued; *Miscellanea Zoologica* (Hague, 1766), and *Spicilegia Zoologica* (2 vols., Berlin, 1767—1804). The Empress Catharine invited him, in 1768, to St Petersburg, where he was well received, and had honours conferred on him, and he was subsequently appointed naturalist to a scientific expedition bound for Siberia, there to observe the transit of Venus. P. spent six years on this journey (1768—1774), exploring in succession the Ural Mountains, the Kirghis Steppes, great part of the Altaian range, and the country around Lake Baikal as far as Kiachta, great part of Siberia, and the steppes of the Volga, returning to St Petersburg in 1774, with an extraordinary treasure of specimens in natural history, which form the nucleus of the Museum of the Academy of St Petersburg. His travels (*Reisen durch verschiedene Provinzen des Russ. Reichs*) were published at St Petersburg (1771—1776), in three volumes, and were followed by his *Sammlung historischer Nachrichten über die Mongol. Völkerschaften* (2 vols., St Petersburg, 1776—1802), and his *Neue nordische Beiträge zur physikalischen und geographischen Erd- und Völkerbeschreibung, Naturgeschichte und Oekonomie* (6 vols., St Petersburg, 1781—1793). Without positively neglecting any branch of natural history, he now devoted himself more particularly to botany; and his magnificent *Flora Rossica* (St Petersburg, 1784—1788), a work which, however, he was not able to complete, and his *Species Astragalorum* (14 parts, Leip. 1800—1804), were among the results of his studies. He published also *Icones Insectorum præcipue Rossicæ Sibiricæque Peculiarium* (Erlangen, 1781, 1783, and 1806); and contributed to a glossary of all the languages of the Russian empire, which was published at St Petersburg. As he wished to live

in the Crimea, the Empress Catharine presented him with an estate in the finest part of that peninsula, where he resided generally from 1796. His *Travels in the South of Russia* were published in 1799 (2 vols., Leip., with volume of plates). After the death of his wife, he went to Berlin, where he died, 8th September 1811. A large and valuable work of his, on the Fauna of Russia, has not yet been published.

PALLAVICINO, PIETRO SFORZA, an Italian historian, son of the Marquis Alessandro Pallavicino of Parma, was born at Rome, 20th November 1607. Much to the disgust of his father, he took priest's orders, and held several important ecclesiastical appointments during the pontificate of Urban VIII. In 1637, he became a member of the Jesuit Society, and was created a cardinal in 1657 by Pope Alexander VII. He died at Rome, 5th June 1667. P. was a fine scholar, and often presided in the famous Roman academy of the *Umoristi*. The best known of all his writings is his *Istoria del Concilio de Trento* (Rome, 1656—1657), intended as a reply to the still more celebrated and liberal, although, by Catholics, deeply suspected, work of Paul Sarpi. Among his other works may be mentioned *Vindicationes Soc. Jes.* (Rome, 1649); *Arte della Perfezione Cristiana—I Fasti Sacri* (the unpublished MS. is in the library of Parma); *Ermengilda*, a tragedy (Rome, 1644); *Gli Avvertimenti Grammaticali* (Rome, 1661); *Trattato dello Stilo e del Dialogo* (Rome, 1662), and *Lettere* (Rome, 1668).

PALLI, a town of Rajputana, in Judpore, stands on the right bank of a branch of the Luni River, in lat. 25° 48' N., long. 73° 24' E. It is an entrepôt for the opium sent from Malwa to Bombay, and is the seat of extensive commerce. It imports European manufactured goods extensively, and is estimated to contain about 50,000 inhabitants.

PALLIOBRANCHIATA. See BRANCHIOPODA.

PALLIUM, the name given in the Roman Catholic Church to one of the ecclesiastical ornaments worn by the pope, by patriarchs, and by archbishops. Its use is held by Roman Catholics to descend from a very early period. It is worn by the pope at all times, as a symbol of his reputed universal and abiding jurisdiction. By archbishops it cannot be worn until it has been solemnly asked for and granted by the pope, and even then only during the solemn service of the great church festivals, and on occasions of the ordination of bishops or of priests, and other similar acts of the archiepiscopal order. The pallium is a narrow annular band of white woollen web, about three inches wide, upon which black crosses are embroidered, which encircle the neck of the archbishop, and from which two narrow bands of the same material depend, one falling over the breast, the other over the back of the wearer. Its material is the subject of much care and ceremonial. It is made wholly or in part from the wool of two lambs, which are blessed annually on the festival, and in the church of St Agnes. During the night of the vigil of the feast of St Peter and St Paul, the *pallia* made of this wool are placed on the altar above the tomb of these apostles, and on the feast of St Peter and St Paul are delivered by the pope to the subdeacon, whose duty it is to keep them in charge. Within three months of his consecration, every new archbishop is obliged to apply to the pope, in person or by proxy, for the pallium; nor is it lawful for him, until he shall have received it, to exercise any act of what is properly archiepiscopal, as contradistinguished from episcopal jurisdiction. Thus, he cannot, for example, call a provincial synod. The pallium cannot be transferred from one archbishop to another, but must be received

direct from the pope. On the archbishop's death, his pallium is interred with him. Its use is held to symbolise the office of the 'good shepherd' bearing the lost sheep on his shoulders, and is connected by some writers with the vesture of the Jewish high-priest in Exod. xxviii. 4. In the mediæval church, the granting of the pallium to archbishops was one of the chief occasions of the tribute which was paid by the national churches to the support of the great central office and dignity of the papacy. In some sees, as, for instance, those of the great prince-bishops of the Rhine, the tribute was as much as 20,000 florins. Roman Catholics, however, maintain that this tribute was not a *payment* for the pallium, but an *offering* to the holy see, made on occasion of the grant of that emblem of jurisdiction.

PALM, a measure of length, originally taken from the width of the hand, measured across the joints of the four fingers. In Greece, it was known as *palaistē*, and was reckoned at 3 inches, or $\frac{1}{4}$ of a cubit, which was their standard unit. The Romans adopted two measures of this name—the one was the Greek *palaistē*, and was called *palmus minor*; the other, which was not introduced till later times, was called *palmus major*, or *palma*, and was taken from the length of the hand, being therefore usually estimated at three times the length of the other. At the present day, this measure varies in a most arbitrary manner, being different in each country, and occasionally varying in the same. The English palm, when used at all, which is seldom, is considered to be the fourth part of an English foot, or 3 inches. The following is a list of the most common measures to which the name palm is given:

	Value in Eng. inches.
Greek <i>palaistē</i> ,	= 3.03375
Roman <i>palmus</i> , or lesser <i>palm</i> ,	= 2.9124
" <i>palma</i> , or greater <i>palm</i> ,	= 8.7372
English palm ($\frac{1}{4}$ of a foot),	= 3.0000
Hamburg palm ($\frac{1}{4}$ of a foot),	= 3.7633
Amsterdam 'round' palm,	= 4.1200
" 'diameter' palm,	= 11.9687
Belgian palm, } properly the <i>decimètre</i> = 3.9371	
Lombard palm,	= 3.3450
Spanish palm, or <i>palmus major</i> ,	= 2.7817
" " " or <i>palmus minor</i> ,	= 8.6616
Portuguese palm, or <i>palmus de Oveira</i> ,	= 8.6616

In Germany and the Low Countries, the palm is generally confined to wood-measurement, while in Portugal it used to be the standard of linear measure.

PALM, JOHANN PHILIPP, a bookseller of Nuremberg, who has acquired an historic celebrity as a victim of Napoleonic justice in Germany. He was born at Schorndorf in 1766, and succeeded his father-in-law, Stein, as a bookseller in Nuremberg, the old name of the firm being retained. In the spring of 1806, a pamphlet, entitled *Deutschland in seiner tiefsten Erniedrigung* (Germany in its Deepest Humiliation), which contained some bitter truths concerning Napoleon, and concerning the conduct of the French troops in Bavaria, was sent by this firm to a bookseller in Augsburg in the ordinary course of trade, and, as P. to the last moment of his life averred, without any regard, on his part, to its contents. Napoleon's police traced it to the shop in Nuremberg, and an investigation was ordered, from which nothing resulted. Palm was in Munich, and perhaps escaped imprisonment there because his name was not the same with that of the firm; but supposing all safe, he returned to Nuremberg, and was there taken prisoner, and examined before Marshal Bernadotte, whose adjutant represented his arrestment as the consequence of direct orders from Paris. An extraordinary court-martial, held at Brunau, to which he was removed, condemned him to death, without any advocate being heard in his defence. All

intercession on his behalf was in vain. General St Hilaire declared that the orders of the emperor were positive; and the sentence was executed at two o'clock on the same day on which it was pronounced. Subscriptions were raised for the family at St Petersburg, to which the Emperor and Empress of Russia personally contributed; in England, and in several German towns, as Berlin, Leipzig, Dresden, and Hamburg. Some French writers have endeavoured to throw the blame of this murder on Marshal Berthier, instead of Napoleon.

PALM OIL. See OIL PALM.

PALM SUNDAY (Lat. *Dominica Palmarum*, or *Dom. in Palmis*), the last Sunday of Lent, is so called from the custom of blessing branches of the palm tree, or of other trees substituted in those countries in which palm cannot be procured, and of carrying the blessed branches in procession, in commemoration of the triumphal entry of our Lord into Jerusalem (John xii.). The date of the origin of this custom is uncertain. The first writer in the West who expressly refers to it is Venerable Bede. The usage certainly existed in the 7th century. A special service is found in the Roman missal, and also in the Greek euchologies, for the blessing of 'branches of palms and olives;' but in many countries, other trees, as in England, the yew or the willow, and in Brittany, the box, are blessed instead. A procession is formed, the members of which issue from the church carrying branches in their hands, and singing a hymn suited to the occasion, of very ancient origin. In the Greek Church, the book of the Gospels is borne in front. In some of the Catholic countries of the West, a priest, or, occasionally, a lay figure, was led at the head, mounted upon an ass, in commemoration of our Lord's entry into the city—a usage which still exists in Spain and in Spanish America. Before their return to the church, the doors have been closed, and certain strophes of the hymn are sung alternately by a choir within the church and by the procession without, when, on the sub-deacon's knocking at the door, it is again thrown open, and the procession re-enters. During the singing of the Passion in the solemn mass which ensues, the congregation hold the palm branch in their hands, and at the conclusion of the service it is carried home to their respective houses, where it is preserved during the year. At Rome, the Procession of the Palms, in which the pope is carried, is among the most striking of the picturesque ceremonies of the Holy Week. In England, Palm Sunday anciently was celebrated with much ceremonial; but the blessing and procession of the palms was discontinued in the Church of England, together with the other ceremonies abolished in the reign of Edward VI.

PALMA. See CANARIES.

PALMA, the capital of the island of Majorca (q. v.) and of the province of Baleares, is situated on the south-west coast of the island, on the Gulf of Palma, which, between Capes Figuera and Blanco, is 18 miles long, and sweeps 12 miles inland. The city is surrounded by orange plantations, and is walled and fortified. The houses, some of which are built of marble, are mostly in the Moorish style of architecture, and a number of the streets are wide and regular. It is the see of a bishop, and contains a Gothic cathedral, simple but beautiful in style, and with a spire which, from the delicate and airy character of its construction, is called the Angel's Tower. Besides other ecclesiastical edifices, the town contains an Exchange—a beautiful and ornate structure in Germano-Gothic—the governor's palace, an academy of medicine and surgery, and a large number of excellent

educational institutions, including three *colegios*. In the port, a mole, 500 yards in length, runs out from the bastions facing the south; and on each side of it are ship-building yards, for the construction of the swift lateen vessels so well known in the Mediterranean. The port is small. The first railway in Majorca was opened from P. to Inca in 1875. Wool, silk, and the cordage for the Spanish navy are manufactured. Though one of the chief marts of Europe in the 13th c., P. now carries on but little commerce. Pop. 58,200.

PALMA CHRISTI. See CASTOR-OIL PLANT.

PALMBLAD, VILHELM FREDRICK, a Swedish writer of considerable merit, and one of the earliest and most zealous promoters of the literature of his native country, was born in 1788 at Liljested, in East Gotland, where his father held a post under the government. While still a student at Upsala, P. purchased, in 1810, the university printing-press, and immediately entered upon the publication of several literary and scientific periodicals, which, being the first of the kind that had ever appeared in the Swedish language, attracted considerable notice, and by their intrinsic merit, contributed materially to the diffusion of general information and the creation of a taste for learning among the general Swedish public. The earliest of these were the *Phosphoros*, a mixed literary journal; the *Poetisk Kalender*, an annual; and the *Svensk Litteratur Tidning*, a literary review, which lasted till 1824. The Swedish writers Atterbom and Hammarskjöld were associated with P. in the management of these journals, and, like him, directed all their efforts to supplant the pseudo-classical school of literature, in favour of the romantic style, and to counteract the false French taste of that period, which, under Gustavus III., had been universally followed in Swedish literature and art. P. successively occupied the chairs of History and Geography and of Greek Literature in the university of Upsala; and at his death in 1852, he left the character of having been one of the most industrious and influential Swedish writers of his day. His principal works are—*Minnestafva öfver Sveriges Regenter* (1831); *Lärobok i nyare Historien* (Ups. 1832); *Handbok i fysiska og politiska Geographien* (1837); *Lärobok i Geographien* (Örebro, 1847); *Grekisk Formkunnab* (Ups. 1845); and in addition to these purely instructive works, among his various novels we may instance his *Familjen Falkensvård* (Öreb. 1844); *Aurora Koningmark* (Öreb. 1846), which rank among the best of their class in Swedish literature. P. was the editor of the great Swedish biography, *Namnkunnige Svenska Män* (Stock. 1835—1852); and besides being an active coadjutor in the direction of the Swedish Literary Society, for which he wrote numerous papers, he was an active contributor to various German works of celebrity, as Ersch and Gruber's *Allgemeine Encyclopädie*, the *Conversations-Lexicon*, &c.

PALMELLA (CRÆ), a family or group of *Alga*, of the order or sub-order *Conserveæ*. In organisation, they are among the lowest of plants; they are, however, universally regarded as vegetable, and do not, like the *Diatomaceæ*, occupy a somewhat doubtful position between the animal and vegetable kingdoms. The P. all grow on damp surfaces, but some under the influence of fresh water, and some of salt. Some appear as a mere powdery layer, the granules of which have little adherence to each other, as Red Snow (q. v.); some of them assume the form of a slimy film or gelatinous mass, as Gory Dew (q. v.); and some are more firm and membranous, so as to have something of the character of a frond. The P. bear so great a

resemblance to the early stages of plants higher in organisation, that doubts are entertained of their right to a distinct place in the botanical system, particularly as their mode of reproduction is not yet well understood. Conjugation has been observed in some of them. They propagate with great rapidity by gemmation, or something like it, some of them sending forth tubular filaments from their cells, the extremities of which dilate into new cells, after which the connecting tube closes, and ceases to exist; whilst in others the multiplication of cells takes place by division or segmentation (see MONAD), and the young plants exhibit remarkable powers of motion for a short time, like zoospores, being furnished with vibratile cilia, by which their motion is produced. Ere long, however, their motion ceases, and the process of segmentation is ready to begin anew. The motile organs and powers of some of the P. in the earlier part of their existence, have led to their being mistaken for animalcules.

PALMER (Lat. *palmifer*, a palm-bearer), the name of one of those numerous classes of PILGRIMS (q. v.), whose origin and history form one of the most interesting studies in the social life of medieval Europe. The Palmer, properly so called, was a pilgrim who had performed the pilgrimage to the HOLY SEPULCHRE (q. v.), and had returned, or was returning home after the fulfilment of his vow. The Palmers were so called from their carrying branches of the oriental palm, in token of their accomplished expedition. On arriving at their home, they repaired to the church to return thanks to God, and offered the palm to the priest, to be placed upon the altar. The palms so offered were frequently used in the procession of Palm Sunday. Even after the time of his return, the religious character of the Palmer still continued; and although his office might be supposed to have ceased with the fulfilment of his vow, many Palmers continued their religious peregrinations even in their native country. They were thus a class of itinerant monks, without a fixed residence, professing voluntary poverty, observing celibacy, and visiting at stated times the most remarkable SANCTUARIES (q. v.) of the several countries of the West. Their costume was commonly the same as that of the ordinary PILGRIM (q. v.), although modified in different countries.

PALMERSTON, VISCOUNT, HENRY JOHN TEMPLE, an English politician, was born at the family mansion, Broadlands, near Romsey, Hants, October 20, 1784. The Temples are of Saxon origin, and the family claim descent from Edwyn, who was deprived of the earldom of Mercia by the Conqueror, and lost his life in defending himself against the Normans in 1071. Sir W. Temple, the diplomatist and patron of Swift, was a member of this family, which removed to Ireland in the time of Elizabeth. The family was ennobled 1722, when Henry Temple was created a peer of Ireland with the dignities of Baron Temple and Viscount Palmerston. His grandson, the second viscount, father of the famous peer, superintended his son's education at Broadlands, and then sent him to Harrow. P. afterwards went to the university of Edinburgh, where he attended the prelections of Dugald Stewart and other professors. He next matriculated at St John's College, Cambridge, whence he was summoned to attend the deathbed of his father, on whose decease, in 1805, P. succeeded to the title. His eminent abilities were early recognised, for he was scarcely of age when the Tory party in the university selected him (1806) as their candidate to succeed Mr Pitt in the representation. The late Marquis

of Lansdowne was the Whig candidate; and Lord Byron, then at Cambridge, in his *Hours of Idleness*, evinces the interest he took in the election. P. was unsuccessful, and again in 1807. He entered parliament, however, in the same year for the borough of Newport, his colleague being Arthur Wellesley, then chief secretary of Ireland. In 1811, he exchanged Newport for the university of Cambridge, enjoyed the distinction of representing his *alma mater* for 20 years, and only lost his seat when he became a member of the Grey administration, and supported the Reform Bill. For the last two years of the unreformed parliament, he sat for the now extinct borough of Bletchingly. At the first election after the Reform Act, he was returned for South Hampshire, but lost his seat at the general election of 1835. He immediately afterwards found a seat for the borough of Tiverton, which he promised never to leave as long as the electors would permit him to represent them. Having traced his representative, we now turn to his official career. P. entered life as a member of the Tory party, and accepted the office of Secretary at War in the Duke of Portland's administration in 1809. This office he held during the successive governments of Mr Perceval, the Earl of Liverpool, Mr Canning, Lord Goderich, and the Duke of Wellington—a period extending from 1809 to 1828. There was ample scope at the War-office for P.'s administrative talents and activity. Our military system swarmed with abuses, and the labour thrown upon the Secretary at War during the Peninsular campaigns was prodigious. In 1817, an attempt was made to assassinate P. by an insane army-lieutenant, named Davis, who fired a pistol at him as he was entering the Horse Guards, the bullet, however, only inflicting a slight wound. P. early attached himself to the Canning section of the Liverpool administration, and he accepted a seat in the cabinet of Mr Canning. His official connection with the Tory party ceased in 1823, when the 'Great Duke' insisted on accepting Mr Huskisson's resignation, which was followed by P.'s retirement. The Duke's government was swept away in the reform flood of 1830; and Earl Grey, who became Prime Minister, offered the seals of the Foreign Office to Palmerston. The European horizon was so disturbed at this crisis, that a great political authority declared that if an angel from heaven were in the Foreign Office, he could not preserve peace for three months. P. falsified the prediction. Louis Philippe then filled the throne of France; and for the first time on record, England and France acted in concert, and without jealousy, under P.'s foreign ministry. He took a leading part in effecting the independence of Belgium, and in establishing the thrones of Queen Isabella of Spain and Queen Maria of Portugal on a constitutional basis. In 1841, P. went out of office with the Whigs on the question of free trade in corn; but on their return in 1846, he resumed the seals of the Foreign Office. His second foreign administration furnished various subjects of hostile party criticism, among which may be mentioned the civil war in Switzerland, the Spanish marriages, the European revolutions in 1848, the rupture of diplomatic relations between Spain and Great Britain, and finally, the affair of Don Pacifico and the quarrel with Greece. A vote of censure on the foreign policy of the government was, in 1850, carried in the House of Lords on the motion of Lord Stanley (afterwards Earl of Derby). A counter-resolution, approving the foreign policy of the government, was thereupon moved by Mr Roebuck in the Lower House. The debate lasted four nights. In a speech of five hours' duration—'that speech,' said Sir Robert Peel, 'which made us

all so proud of him'—P. entered upon a manly and dignified vindication of his foreign policy; and Mr Roebuck's motion was carried by a majority of 46. In December 1851, the public were startled at the news that P. was no longer a member of the Russell cabinet. He had expressed his approbation of the *coup d'état* of Louis Napoleon, without consulting either the premier or the Queen; and as explanations were refused, her Majesty exercised her constitutional right of dismissing her minister. P. avenged himself, as soon as parliament met, by shattering the Russell administration to pieces on a comparatively trifling question regarding the militia. He refused an offer from the Earl of Derby to join the government which he was commissioned to form, but accepted the post of Home Secretary in the coalition administration of the Earl of Aberdeen in 1852. The fall of this government, on Mr Roebuck's motion for a Sebastopol committee, placed P. in his 71st year in the position of prime minister, to which he was unanimously called by the voice of the nation. He vigorously prosecuted the Russian war until Sebastopol was taken, and peace was made. His government was defeated in March 1857, on Mr Cobden's motion, condemnatory of the Chinese war. Parliament was dissolved, and P. met the House of Commons with a large majority. But his administration fell in February 1858, upon the Conspiracy Bill, intended to protect the French emperor against the machinations of plotting refugees. A short Conservative administration followed; but in June 1859, P. was again called to the post of First Lord of the Treasury, which he continued to fill up to his death. It was his ambition to be considered the minister of a nation rather than the minister of a political party; and his opponents have been constrained to admit that he held office with more general acceptance than any English minister since the time of the great Lord Chatham. As an orator, he was usually homely and unpretending, but always sensible and practical. He was a dexterous tactician, and a ready, witty, and often brilliant debater. He was popular as a minister, because he was thoroughly English in his ends and aims. Even his robust health, manly bearing, and physical vigour were elements of his popularity, because they were regarded as a glorification of the English sports, which he was never ashamed to patronise. He desired nothing so ardently as to promote the wealth and grandeur of Great Britain, and his national character and national spirit were thoroughly appreciated by his countrymen. He married, in 1839, the widow of the fifth Earl of Cowper, daughter of the first Viscount Melbourne. As he died without issue, and his only brother died unmarried, the title became extinct on P.'s decease, Oct. 18, 1865. See *Life of P.* by Sir Henry Lytton Bulwer (Lord Dalling), continued by Evelyn Ashley.

PALMER-WORM, a name given to many large kinds of grub, the larvæ of coleopterous insects, destructive to vegetable substances of various kinds. It is used in the English version of the Old Testament as the translation of the Hebrew *gazam*, rendered *kampe* by the Septuagint, which modern Hebrew writers and others very generally regard as a kind of locust, although more probably it is either the grub of a coleopterous or the caterpillar of a lepidopterous insect.—See Kitto in *Pictorial Bible*, on Joel i. 4.

Palmer-flies are much used by anglers on the English streams, and are at certain seasons excellent lures for trout, &c.

PALMETTO (*Sabal palmetto*, or *Chamærops palmetto*), a species of palm, a native of maritime parts of North America, as far north as lat. 35°,

which is further north than any other American species of palm is found. It attains a height of 40—50 feet, and has a crown of large palmated leaves, the blade from one foot to five feet in length and breadth, and the footstalk long. The flowers are small, greenish, and in long racemes; the fruit black, about as long as a pea-pod, and uneatable. The leaves are made into hats. The terminal bud or *cabbage* is eaten. The wood is extremely porous; but is preferred to every other kind of wood in North America for wharfs, as it is very durable, and not liable to be attacked by worms.—The *Chamærops* (q. v.) *humilis* of the south of Europe is also called Palmetto.

PALMETTO-LEAVES, the leaves of the *Palmyra* (q. v.) palm, *Borassus flabelliformis*, which grows extensively in India and Polynesia. The leaves have great value as a material for the manufacture of hats, mats, &c., and for this purpose are frequently imported into Europe. In their native country, they are used as thatch, and for a great variety of other useful applications.

PALMI'PEDÉS, or **WEB-FOOTED BIRDS**, also called **NATATORES**, or **SWIMMERS**, an order of birds, the *Anseres* of Linnaeus, very natural and universally recognised by ornithologists, having the feet specially formed for swimming, and the toes *wedged*, i. e., connected by a membrane, at least those which are directed forwards. In swimming, the feet are contracted when drawn forwards, the toes being brought together, and expanded to their utmost extent in the backward stroke. In accordance with their aquatic habits, the P. are further characterised by a boat-like form, calculated to move through the water with little resistance; and by a dense and polished plumage, oiled by a secretion from certain glands near the tail, very impervious to water; whilst warmth is further secured by a clothing of down, more or less abundant, beneath the feathers. They are remarkable for the length of the breast-bone (*sternum*), and the neck is often longer than the legs, a thing very unusual in birds, so that they can plunge the head far down in search of food. The length of the wings differs very much in different sections of the order, and with it the power of flying; as does also the power of diving, which some possess in a high degree, and others, even of the same family, in a very inferior degree. To this order belong geese, swans, ducks, divers, auks, guillemots, puffins, penguins, petrels, albatrosses, gulls, terns, shearwaters, noddies, pelicans, cormorants, frigate-birds, gannets, darters, tropic-birds, &c.

PALMITIC ACID ($\text{HO}, \text{C}_{15}, \text{H}_{31}, \text{O}_2$) is one of the most important of the *Fatty Acids*, represented by the general formula $\text{HO}, \text{C}_n, \text{H}_{2n+1}, \text{O}_2$ (see **OILS AND FATS**). In a pure state, when crystallised from alcohol, it occurs in the form of beautifully white acicular crystals arranged in tuft-like groups. These crystals are devoid of odour or taste, communicate a fatty feeling to the finger, fuse at 143° F., and solidify on cooling in the form of crystalline scales. This acid is lighter than water, in which it is perfectly insoluble; but it dissolves freely in boiling alcohol and in ether, and the solutions have a distinctly acid reaction. In small quantities it may be distilled without decomposing, if the heat be carefully regulated. The neutral palmitates of the alkalies constitute soaps, and are soluble in water; if, however, their solutions are largely diluted with additional water, they are decomposed, an insoluble acid salt being precipitated, while a portion of the base remains in solution. The addition of chloride of sodium (common salt) to a solution of an alkaline palmitate produces a similar

effect. The other most important compounds of palmitic acid are those which it forms with glycerine and with cetyl ether. With glycerine this acid forms three compounds, viz., a triglyceride or tripalmitate (constituting the ordinary PALMITINE of chemists), a diglyceride, and a monoglyceride. In addition to its existence in the form of palmitine, palmitic acid is found in a free state in old palm oil. In combination with cetyl ether, or of oxide of cetyl, whose composition is represented by the formula $C_{25}H_{52}O$, it is the main constituent of Spermaceti (q. v.), which is in fact essentially a palmitate of oxide of cetyl ($C_{25}H_{52}O.C_{25}H_{51}O_2$); and as a palmitate of oxide of melissyl—a substance which will be noticed in the article WAX—it is the chief ingredient of bees-wax.

PALMITINE is a white fat, usually occurring, when crystallised from ether, in the form of a mass of small scaly crystals. According to Duffy, it occurs like the allied fat stearine in three modifications, each of which has a different melting-point—viz., $114^{\circ}8$, 143° , and 145° . On cooling, it solidifies into a wax-like mass, of lower specific gravity than water, and insoluble in that fluid, but readily soluble in ether and in boiling alcohol. It is a constituent of almost every kind of fat, and is the preponderating ingredient in those of a semi-solid consistence, and in many oils. It receives its name from the abundance in which it occurs in palm oil, and it may readily be obtained from this source by removing the liquid portion (the oleine) by pressure, and purifying the remaining palmitine by crystallisation from ether, or a mixture of ether and alcohol. It has been stated in the article on Glycerine (q. v.) that the composition of that substance may be represented by the formula $C_3H_5O_2.3HO$. When palmitic acid unites with it to form a triglyceride (or the substance usually recognised as palmitine), three atoms of the anhydrous acid expel and replace the three atoms of water in the glycerine, and the resulting compound, palmitine, is consequently represented by the formula $C_3H_5O_2 + 3(C_{25}H_{51}O_2)$, or $C_{78}H_{155}O_7$.

PALMS (*Palma* or *Palmaceæ*), a natural order of endogenous plants, not excelled in importance by any order in the vegetable kingdom except Grasses. They are generally tall and slender trees, often of gigantic height, without a branch, and bearing at the summit a magnificent and graceful crown of very large leaves. The stem is sometimes, however, of humble growth, and more rarely it is thick in proportion to its height; sometimes, but rarely, it is branched, as in the Doom (q. v.) Palm; and sometimes, as in Rattans (q. v.), it is flexible, and seeks support from trees and bushes, over which it climbs in jungles and dense forests, clinging to them by means of hooked spines. Some of the species with flexible stem attain a prodigious length, ascending to the tops of the highest trees, and falling down again. Rumphius asserts that they are sometimes 1200, or even 1800 feet long. Whatever the form or magnitude of the stem of a palm, it is always woody, and the root is always fibrous. It is only towards its circumference, however, that the stem is hard, and there in many species it is extremely hard; but the centre is soft, often containing, when young, a great quantity of starch (sago), and sometimes filled, when old, with a mass of fibres which can be separated without difficulty. Concerning the structure of the stem, see ENDOGENOUS PLANTS. The stem is generally marked externally with rings or scars, where former leaves have been attached; sometimes it is rough with the remaining bases of the leaves, and part of it is sometimes covered with their fibrous appendages. No other plants have leaves so large as many of the P.; the largest of all are those of some of the fan-leaved P., but there

are P. with pinnate leaves 50 feet long and 8 feet broad, and undivided leaves are to be seen 30 feet long by 4 or 5 feet broad. There are, however, also small P., and P. with flexible stems, which have small leaves. The number of the large leaves which form the crown of even the most magnificent palm is never great. Whatever the size or form of the leaves, they are always stalked, the stalk being often in dimensions equal to a large bough of a great oak or other such tree. The leaves are commonly pinnated, the number of pinnules or leaflets being often very great; but about one-sixth of the whole number of known species of P. have fan-shaped leaves, and a few species have undivided leaves. The leaves are in all cases persistent, only falling off in succession as the palm advances in growth, and new ones are formed at the summit. The flowers are sometimes hermaphrodite, sometimes unisexual; the same tree having sometimes male, female, and hermaphrodite flowers, whilst other species are monœcious and others diœcious. The perianth has six divisions, three outer and three inner; there are generally six, rarely three stamens; the ovary is composed of three carpels, distinct or united, each with one cell containing one ovule. The flowers are small, but are often produced in dense masses of very striking appearance. Humboldt reckons the number of flowers on a single palm (*Alfonsia amygdalina*) as about 600,000, and every bunch of the Seje Palm of the Oronoco consists of about 8000 fruits. The flowers are produced on scaly spadices, often much branched, and enclosed, before expanding, in leathery or woody spathe, often very large, and sometimes opening by bursting with a loud explosion. The flowers of some P. emit a very powerful odour, which attracts multitudes of insects. The fruit is sometimes a kind of berry, sometimes a drupe, either with a fleshy or a fibrous covering; and sometimes contains a very hard and bony nut. The fruit is sometimes only of the size of a pea or a cherry; sometimes, notwithstanding the smallness of the flowers, it is of very large size, of which the cocoa-nut is a familiar example.

Palms are mostly natives of tropical countries, being found almost everywhere within the tropics, and forming, perhaps, the most striking characteristic of tropical vegetation. The tropical parts of America, however, particularly abound in them, producing a far greater number of species than any other part of the world. A few species are found in temperate regions; one species only, *Chamaerops humilis*, being a native of Europe, and extending as far north as lat. 44° , whilst the northern limit of P. in Asia is about lat. 34° , and in North America, lat. 35° . In South America, the southern limit of P. is lat. 36° ; in Australia, it is lat. 35° ; in Africa, no native species is found further south than lat. 30° ; but in New Zealand, one species extends as far south as lat. $38^{\circ}22'$. Some of the species, however, which are found in tropical America grow in mountain regions bordering upon the limits of perpetual snow. Some P. have very narrow geographical limits; the cocoa-nut palm is by far the most extensively distributed species. Some, like the cocoa-nut, grow in maritime, others in inland districts. Some grow on dry and sandy ground, others in the richest alluvial soil, and some in swampy situations; some in open districts, others in dense forests. Some species are generally found singly, some in groups; some even cover tracts of country in which no other tree appears.

The uses of P. are many and various; there is almost no species which is not capable of being applied to some use. Tribes in the lowest grade of civilisation depend almost entirely on particular species of palm, as the cocoa-nut palm, for the

supply of all their wants. The fruit of some species is eaten; sometimes the fleshy part of the fruit, sometimes the kernel of the nut. The importance of the date and the cocoa-nut needs only to be alluded to; but in this respect they far excel the fruits of all other palms. A grateful beverage is made from the fruit of some P. (see ASSAI), consisting simply of a mixture of the pulp with water; but a kind of wine can be obtained also by fermentation (see DATE). A kind of beverage more generally used is the sap of palm-trees, either fresh or fermented (*palm-wine* or *toddy*), from which also a kind of spirits called Arrack (q. v.) is obtained by distillation; whilst from the fresh sap, boiled down, sugar is obtained—the *jaggery* of the East Indies. The sap of various species of palm is collected and used for these purposes, and that of many others is probably not less suitable. The pulp of the fruit of some species, and the kernel of others, yield bland fixed oil useful for various purposes. See OIL PALM and COCOA-NUT. The soft and starchy centre of the stem of some P. affords a very important and abundant article of food. See SAGO. The terminal bud, or *cabbage*, of some species is boiled for the table; and although the taking of the bud is death to the tree, this is little regarded where vegetation goes on with a rapidity and luxuriance unknown in the colder parts of the world. The young sprouts arising from the seeds of P., when they have begun to vegetate, are another esculent of tropical countries. From the stems of some species of palm, as the Wax Palm (q. v.) of the Andes, and from the leaves of some, as the Carnahuba Palm (q. v.), wax is obtained, which is used for the same purposes as bees-wax. The wood of P. is used in house building, and for many other purposes; some affording very hard and beautiful wood for ornamental work, whilst others are suitable only for coarse purposes. The great leaf-stalks are also used for some of the purposes of timber. The stems of the most slender species are used for walking-sticks, &c., and, split or unsplit, for wicker-work. See RATTAN. The leaves of many P. are used for thatching houses. The spathes of some species are used as vessels or bags. The fibres of the leaf, the fibres connected with the leaf-stalk, the fibres of the rind of the fruit, and the fibres of the stem of different kinds of P. are used for making cordage, mats, nets, cloth, &c. The most important of these fibres are Coir (q. v.) or Cocoa-nut Fibre, Gomuto (q. v.) or Eجو Fibre, and Piassaba (q. v.). The coarsest fibres are employed as bristles for making brushes, &c. Stripes of the delicate epidermis of the young unopened leaves of some South American P. are twisted, and so used for making a kind of thread; hammocks made of which are highly valued. See ASTROCARYUM. The leaves of the Palmyra Palm and Talipot Palm are used in some parts of the east for writing upon, an iron style being employed instead of a pen. One of the kinds of the resinous substance called *Dragon's Blood* is obtained from the fruit of a palm. The Betel (q. v.) Nut, abounding in catechu, is the fruit of a palm. The fruit of many P. is very acrid. The ashes of the fruits of some American species are used by the Indians as a substitute for salt, probably on account of potash, or some salt of potash, which they contain; and much potash may be obtained from the stems and leaves of palms. Vegetable Ivory (q. v.) is the kernel of the fruit of a palm; and somewhat similar to it in quality is the Coquilla Nut (q. v.). But a complete enumeration of the uses to which P. and their products are applied is almost impossible.

Some of the more important species of P. are noticed in separate articles.

About five hundred species are known; but it is

probable that many are still undescribed. The most complete work on P. is the monograph by Martius, *Genera et Species Palmarum* (3 vols., large folio, Munich, 1823–1845), a magnificent work, with 219 coloured plates; but many new species have been discovered since its publication.

The cultivation of P. in hothouses is attended with great expense. Separate houses are devoted to them in a few gardens, of which the greatest is that at Kew. A very fine palm-house has been erected in the Botanic Garden of Edinburgh. P. are cultivated in hothouses merely as objects of interest, and for the gratification of a refined taste, never for the sake of their fruit or any other product.

PALMYRA, the name given by the Greeks to a great and splendid city of Upper Syria. Its original Hebrew name was *Tadmor*, which, like the Greek word, means 'city of palms.' It was built, according to the writers of Kings (Book I. chap. ix. verse 18) and Chronicles (Book II. chap. viii. verse 4), by Solomon in the 10th c. a. c.; but it is more probable that he only enlarged it. It occupied a fertile oasis, well watered, and abounding in palm-trees. Barren and naked mountains overlook it from the west, and to the east and south stretches the illimitable sandy desert. P. was, in the Solomonic age, a bulwark of the Hebrew kingdom against the wandering hordes of Beduins; but its early history is obscure and insignificant. After the fall of Seleucia, it became a great centre of commercial intercourse between the east and the west of Asia. Its commercial importance, wealth, and magnificence greatly increased after the time of Trajan, who subjected the whole country to the Roman empire. In the 3d c., Odenathus, a Syrian, founded here an empire, which, after his murder, rose to great prosperity under his wife, Zenobia (q. v.), and included both Syria and Mesopotamia; but this was not of long duration, for the Roman Emperor Aurelian conquered it in the year 275, and the city was soon after almost entirely destroyed in revenge for the slaughter of a Roman garrison. It never recovered from this blow, although Justinian fortified it anew. The Saracens destroyed it in 744. A village called Tedmor, inhabited by a few Arab families, now occupies the site. The ruins of the ancient city, white and dazzling in the Syrian sun, excite at a little distance the admiration of all beholders; but when examined in detail, they are said to be far from imposing, though in regard to this latter point opinions differ. They were visited by English merchants resident at Aleppo in 1691, and again by Messrs Wood and Dawkins in 1751, and since then by a vast number of travellers. The ruins of a temple of Baal, the sun god, are, however, confessedly magnificent. The language of ancient Palmyrene appears, from inscriptions which remain, to have been an Aramaic language. See Murray's or Baedeker's *Handbook for Syria and Palestine*; Vogué's *Syrie Centrale*.

PALMYRA PALM (*Borassus flabelliformis*), a species of palm with a magnificent crown of fan-shaped leaves, a native of the East Indies. The stem attains a height of 25–40, or even 60 feet, and tapers slightly upwards. The leaves are about four feet long, with stalks of about the same length, the stalks spiny at the edges; each leaf having 70–80 rays. The fruit is somewhat triangular, about the size of a child's head; having a thick, fibrous, and rather succulent yellowish-brown or glossy black rind, and containing three seeds each as large as a goose's egg. The P. P. is the most common palm of India, growing spontaneously in

many districts, cultivated in others, and reaching as far north as lat. 30°. It is of slow growth; and the wood near the circumference of the stem in old trees is very hard, black, heavy, durable, susceptible of a high polish, and valuable, easily divided in a longitudinal direction, but very difficult to cut across. The *P. P.* abounds greatly in the north of Ceylon, forming extensive forests; and the timber is exported to the opposite coast of India, being of superior quality to that which is produced there. It is much used in house building. The stalks of the leaves are used for making fences, &c. The leaves are used for thatching houses; for making baskets, mats, hats, umbrellas, and large fans; and for writing upon. Their fibres are employed for making twine and small rope; they are about two feet long, and very wiry. A fine down found at the base of the leaf-stalks is used for straining liquids, and for stanching wounds. The *P. P.* yields palm-wine, and of course also arrack and sugar (*jaggery*). It furnishes great part of the palm-wine, sugar, and arrack of India. See ARRACK. The fruit is cooked in a great variety of ways, and used for food. The seeds are jelly-like, and palatable when young. A bland fixed oil is extracted from the fruit. The young plants, when a few inches high, are esteemed as a culinary vegetable, being boiled and eaten generally with a little of the kernel of the cocoa-nut; and sometimes they are dried and pounded into a kind of meal. Multitudes of the inhabitants of the north of Ceylon depend almost entirely on the *P. P.* for the supply of all their wants. In the 'Palmyra Regions' of the Southern Dekkan vast numbers of the people subsist chiefly on the fruit of this palm.

The Deleb Palm (q. v.), so important to the inhabitants of Central Africa, is believed to be nearly allied to the Palmyra Palm.

PALMYRA WOOD. Properly this name applies only to the wood of the Palmyra palm (*Borassus flabelliformis*), but it is generally used for all kinds of palm-tree wood imported into this country, amongst which very much is the wood of the cocoa-nut palm, *Cocos nucifera*, and the allied species *C. plumosa*. These woods are also called *Speckled Wood* and *Porcupine Wood* by the dealers—the former name being applied to those veneers cut transversely, and shewing the ends of numerous black fibres mixed with the lighter coloured portions; and the latter to longitudinal sections, in which the mixed black and white fibres much resemble porcupines' quills.

PALO BLANCO (*Flotovia dicanthoides*), a large tree, a native of Chili, the wood of which is white, and very useful and durable. It is remarkable as one of the few large trees belonging to the natural order *Compositae*.

PALOLO, or BALOLO (*Palolo viridis*), a dorsi-branchiate annelid, allied to the Lug-worm, extremely abundant at certain seasons in the sea above and near the coral reefs which surround many of the South Sea Islands, as the Samoa Islands and the Fiji Islands. The body is cylindrical, slightly tapering at both ends, divided into nearly equal joints, each joint with a small tuft of gills on each side. In thickness, the *P.* resembles a very fine straw; it is about three inches long, generally of a greenish colour, with a row of round black spots; but the colour varies to red, brown, and white. These annelids make their appearance in great multitudes, apparently rising out of the coral reefs, and with a periodical regularity which is very remarkable. They are eagerly sought after by the islanders, who are on the watch for their appearance, and go out in canoes early in the morn-

ing to take them by means of nets; but they often occur in such numbers that the water seems to be full of them, and they may be grasped by handfuls.

Palolo Viridis (copied from Seemann's *Viti*):

1, the entire animal, half natural size; 2, portion of body, slightly magnified; 3, magnified figure of its head, with its three frontal tentacula and eyes; 4, posterior extremity, dorsal aspect.

They are a delicacy of which the South Sea islanders are very fond. To prepare them for use, they are wrapped in bread-fruit leaves, and cooked for twelve or eighteen hours in an oven.

PALPI (from the Lat. *palpo*, I touch) are organs occurring in Insects, Crustaceans, and Arachnidans. In Insects, one or two pair of jointed appendages bearing this name are attached to the maxillæ, while one pair is attached to the labium; and in the higher Crustaceans, similar appendages are attached to the mandibles and foot-jaws. In both these classes, the palpi probably serve, through the sense of touch, to take cognizance of the qualities of the substances which are employed as food. In the Arachnidans, the palpi are attached to the maxillæ only; and vary exceedingly in form and functions. In the scorpions, for instance, they are extremely developed, and terminate in pincers which resemble the chæls (or pincers) of crabs and lobsters; while in the spiders, they terminate in a single movable claw in the female, and in the male the last joint is dilated, and acts as an accessory generative organ.

PALPITATION is the term used to signify inordinately forcible pulsations of the heart, so as to make themselves felt, and frequently to give rise to a most troublesome and disagreeable sensation. It may be either functional or a symptom of organic disease of the heart. Here we shall merely consider it as a functional disorder. Although it may be persistent, it far more frequently comes on in paroxysms, which usually terminate within half an hour, recurring afterwards quite irregularly, sometimes daily or several times a day, and sometimes not till after a long interval. The attack often comes on under some mental or physical excitement, but sometimes when the patient is quite composed, or even asleep. If the paroxysm is a severe one, the heart feels as if bounding upwards into the throat; and there is a sensation of oppression over the cardiac region, with hurried or even difficult respiration. Excluding organic diseases, the causes of this affection are either (1) an abnormally excitable

condition of the nerves of the heart, or (2) an unhealthy condition of the blood.

1. Amongst the causes of disturbed innervation may be especially noticed the abuse of tea (especially green tea), coffee, spirits, and tobacco. Any irritation of the stomach and intestinal canal may be reflected to the heart; and hence palpitation may frequently be traced to flatulence, undue acidity, and intestinal worms, especially tape-worms. Everything that causes pressure on the heart, such as tight lacing, abdominal dropsy, or an enlarged uterus, is also liable to occasion this affection.

2. If the blood is abnormally rich and stimulating it may give rise to palpitation, as in Plethora (q. v.); but the opposite condition, known as Anæmia (q. v.), is a much more common cause of this affection. In anæmia the blood is watery and deficient in fibrine, and (far more) in red corpuscles; and being thus in an unnatural state, it acts as an unnatural stimulant, and induces frequent, although not usually strong pulsations. In cases of this kind, singular murmurs (not unlike those which are heard when we apply certain shells to the ear) are heard on applying the stethoscope to the neck over the course of the great jugular veins.

The age at which palpitation most usually comes on is from 15 to 25 years; and the affection—especially if it arise from anæmia—is very much more common in the female than in the male sex.

The treatment of palpitation must entirely depend upon its cause. The use of all nervous stimulants (tea, coffee, alcohol, and tobacco) should be suspended or abandoned. If the patient is clearly plethoric, with a full strong pulse, he should take saline cathartics, and live upon comparatively low diet (including little animal food) until this condition is removed. When, on the other hand, the palpitation is due to an anæmic condition, the remedies are preparations of iron, aloetic purgatives, an abundance of animal food, bitter ale, the cold shower-bath, and moderate exercise.

PA'LSY. See PARALYSIS.

PAMIR (also aptly called *Bam-i-dunya*, 'Roof of the World'), a mountainous region in Central Asia, forming the nucleus of the Central Asian highland system. Hither converge the Hindu Kush, the Himalaya, the Kuen-lun, and the Tian-Shan Mountains. The P. is not so much a plateau or region of lofty plateaux, as a vast mountainous district some 30,000 square miles in area, broken up into ridges and valleys. The ridges rise from 6000 to 9000 feet above the valleys, and the culminating points attain in some cases the great height of 25,000 feet above sea-level.

PAMLICO SOUND, on the coast of North Carolina, U.S., is separated from the ocean by long, narrow islands of sand, an angle of the largest forming Cape Hatteras, and connected with the ocean by narrow passages; it is 80 miles long, and from 10 to 30 miles wide, and receives the Neuse and Pamlico Rivers.

PA'MPAS (in the Quichua tongue, 'a valley' or 'plain') is a term frequently employed in a general sense as a designation of Southern American plains, in contradistinction to the 'prairies' of North America. It is also used in Peru as a general designation of tracts of level land either on the coast or among the mountains. The chief pampas in Peru are those of the Sacramento. But in its more special and proper signification, the word pampas is given to the immense and partly undulating plains bounded by the Rio Negro of Patagonia, the La Plata and Paraguay, and the base of the Cordilleras. These plains during the wet season afford abundant pasture to the many herds of wild oxen and

horses which roam over them, but they become rapidly parched under the burning heat of the sun, except in the low-lying tracts, or along the banks of rivers. The most fertile of the pampas lie westwards towards the Cordilleras. From the rapid alternation of vigorous growth with parching drought, the growth of trees is impossible, and their place is accordingly supplied by sparse groups of stunted shrubs. The soil, which is in general poor, is a diluvium composed of sandy clay, and abounds in the bones of extinct mammals. Strips of waterless desert, known as *travesias*, stretch across the pampas; these *travesias* are destitute of all vegetation with the exception of a few bushes, and are markedly distinct in geological character. The soil of the pampas is more or less impregnated with salt, and saltpetre abounds in many places. The wild animals of the pampas are horses, oxen (both introduced by the Spaniards), nandous, and guanacos. The skins of the horses and oxen, and the flesh of the latter, form a most important item in the trade of this region. The half-white inhabitants of the pampas are called Guachos (q. v.). The whole area of the pampas has been estimated at about 1,500,000 square miles.

PAMPAS GRASS (*Gynerium argenteum*), a grass which covers the pampas in the south of Brazil and more southern parts of South America, and has been introduced into Britain as an ornamental plant. It is quite hardy, and its tufts have a splendid appearance. The leaves are six or eight

Pampas Grass (*Gynerium argenteum*).

feet long, the ends hanging gracefully over; the flowering stems ten to fourteen feet high; the panicles of flowers silvery white, and from eighteen inches to two feet long. The herbage is too coarse to be of any agricultural value. The male and female flowers are on separate plants; in panicles; the spikelets 2-flowered, one floret stalked, and the other sessile; the paleæ of the female florets elongated, awn-shaped, and woolly.—Another species

of the same genus, *G. saccharoides*, also a Brazilian grass, yields a considerable quantity of sugar.

PAMPELUNA, or **PAMPLONA**, a fortified city of Spain, capital of Navarre, of which it is the key, occupies an eminence not commanded by any neighbouring height, on the left bank of the Arga, a tributary of the Ebro, 111 m. N.N.W. of Zaragoza by railway, and 200 miles north-north-east of Madrid. The citadel, overlooking the river and commanding the plain, is a regular pentagon, each side being 1000 feet in extent, and is connected with the city by an esplanade or glacis. Magnificent views of the Pyrenees on the north are obtained from the citadel, and there are several very pleasant promenades. The *Cuenca* (plain) of P. is about 30 miles in circumference; and although the climate is somewhat chilly and damp, the gardens are fruitful and the meadows verdant. The city is well built and clean; water is brought from hills about nine miles distant, by means of an aqueduct built after the solid Roman style by Ventura Rodriguez, and a portion of which, 2300 feet in length, is supported on 97 arches, 35 feet in span, and 65 feet in height. The town contains a number of squares with fountains, a theatre, and the regular *plaza de toros*—bull arena—capable, it is said, of containing 10,000 people. Agriculture, the wine trade, and the manufacture of linens and leather, are the only noteworthy branches of industry. P. was blockaded by the Carlists in 1874. Pop. (1877) 25,630.

P. was called by the ancients *Pompeipolis*, from the circumstance of its having been rebuilt by the sons of Pompey in 68 B.C. It was taken by the Goths in 466, by the Franks under Charlebert in 542, and again under Charlemagne in 778. It was subsequently for a time in possession of the Moors, who corrupted the name Pompeipolis into *Bambilonah*, whence the modern Pamplona. In later times it was seized by the French in 1808, and held by them till 1813, when it fell into the hands of the allies under the Duke of Wellington.

PAMPHLET (most probably from Latin *Pamphila*, a female historian of the first century, who wrote numerous epitomes of history. The word must have come through the medium of French, as it occurs in the *Testament of Love*, but Littré says the modern French word is borrowed from the English), a small book consisting of a sheet of paper, or a few sheets stitched together, but not bound. It generally contains a short treatise on some subject, political or otherwise, which is exciting public attention at the time of its appearance. It was not till about the middle of the 16th c. that pamphlets began to be of common use in political and religious controversy in England and France. Under the second French empire, political pamphlets used to appear from time to time, believed to be written under imperial dictation, as feelers of public opinion.

PAMPHYLIA, anciently a country on the south coast of Asia Minor, with Cilicia on the east and Lycia on the west. It was originally bounded on the inland or northern side by Mount Taurus, but afterwards enlarged, so as to reach the confines of Phrygia. P. is mountainous, was formerly well wooded, and had numerous maritime cities. The inhabitants—a mixed race of aborigines, Cilicians, and Greek colonists—spoke a language the basis of which was probably Greek, but which was disfigured and corrupted by the infusion of barbaric elements. Their coins shew that they had adopted to some extent the religion, arts, and games of the Hellenic race. Its political history is unimportant. Along with Phrygia and Lycia it fell to the share of Antigonos on the partition of the Macedonian empire. It afterwards passed successively into the

hands of the Græco-Syrian princes, the kings of Pergamus, and the Romans.

PAN, among the Greeks, the chief god of pastures, forests, and flocks. The later rationalising mythologists, misconceiving the meaning of his name, which they confounded with *pan*, 'the whole,' or 'the universe,' whereas it is more probably connected with *pas* (Lat. *pasco*), 'to feed,' 'to pasture,' represented him as a personification of the universe, but there is absolutely nothing in the myth to warrant such a notion. Pan neither in his genius nor his history figures as one of the great principal deities, and his worship became general only at a comparatively late period. He was, according to the most common belief, a son of Hermes (Mercury) by the daughter of Dryops; or by Penelope, the wife of Ulysses; while other accounts make Penelope the mother, but Ulysses himself the father—though the paternity of the god is also ascribed to the numerous wooers of Penelope in common. The original seat of his worship was the wild hilly and wooded solitudes of Arcadia, whence it gradually spread over the rest of Greece, but was not introduced into Athens until after the battle of Marathon. Homer does not mention him. From his very birth his appearance was peculiar. He came into the world with horns, a goat's beard, a crooked nose, pointed ears, a tail, and goat's feet; and so frightened his mother that she ran off for fear, but his father, Hermes, carried him to Olympus, where all the gods, especially Dionysus (Bacchus), were charmed with the little monster. When he grew up, he had a grim shaggy aspect, and a terrible voice, which bursting abruptly on the ear of the traveller in solitary places—for Pan was fond of making a great noise—inspired him with a sudden fear (whence the word *panic*). It is even related that the alarm excited by his blowing upon a shell decided the victory of the gods over the Titans. He was the patron of all persons occupied in the care of cattle and of bees, in hunting and in fishing. During the heat of the day he used to take a nap in the deep woods or on the lonely hillsides, and was exceedingly wroth if his slumber was disturbed by the halloo of the hunters. He is also represented as fond of music, and of dancing with the forest nymphs, and as the inventor of the syrinx or shepherd's flute, also called Pan's pipe. Cows, goats, lambs, milk, honey, and new wine were offered to him. The fir-tree was sacred to him, and he had sanctuaries and temples in various parts of Arcadia, at Troezena, at Sicyon, at Athens, &c. The Romans identified the Greek Pan with their own Italian god Inuus, and sometimes also with Faunus. See FAUN.

When, after the establishment of Christianity, the heathen deities were degraded by the church into fallen angels, the characteristics of Pan—viz., the horns, the goat's beard, the pointed ears, the crooked nose, the tail, and the goat's feet—were transferred to the Devil himself, and thus the 'Auld Hornie' of popular superstition is simply Pan in disguise.

PANAMA, a city and seaport of the republic of Colombia, in S. America, capital of the 'state' of the same name, at the head of the Bay of Panama, on the southern shore of the isthmus of the same name, in lat. 8° 56' N., long. 79° 31' W. It occupies a tongue of land which extends some distance out to sea in shallow waters. The harbour is safe, but vessels of more than 80 tons burden cannot approach within two miles of the shore. Large vessels anchor at a distance of three miles, near the island of Perico. The important edifices of the city include a beautiful cathedral, a college, and several convents, all of which, however, are falling into decay. There is considerable trade with

Europe in pearls, mother-of-pearl, shells, and gold-dust, obtained in the vicinity. P. is chiefly important, however, as the Pacific terminus of the Panama Railway. This railway was completed in 1855, is about 48 miles in length, and connects P. on the Pacific with Aspinwall colony on the Atlantic. By means of it the route to California was much shortened, and mails were carried over it till the completion of the Pacific Railway. Pop. (1870) 18,378. The former city of P., the seat of the Spanish colonial government established in 1518, stood six miles N.-E. of P., and is now a heap of ruins.

PANAMA, ISTHMUS OF, is that portion of the narrow ridge of mountainous country connecting Central and South America, which is bounded on the W. by the frontier of Costa Rica, and on the E. by the surveyed inter-oceanic route from the Bay of Caledonia on the N. to the Gulf of San Miguel on the S. or Pacific side. It extends in long. from 77° to 83° W. The 'State' of P., one of those which form the United States of Colombia, is co-extensive with the isthmus of the same name. Area, 29,756. Pop. (1870) 220,542. P. contains the provinces of Panama, Azuero, Chiriqui, and Veraguas. The Isthmus is traversed throughout by a chain of mountains, forming the barrier between the Atlantic and Pacific Oceans, and of which the highest peak is that of Picacho (7200 feet) in the west. Numerous streams, the largest of which is the Tuira (162 miles long, and navigable for 102 miles), fall into both oceans. On the Pacific shores are numerous beautiful islands, among which Las Perlas, so called from their pearl fisheries, and the island of Coiba, are the chief. On the north coast, the principal harbours are the Chiriqui Lagoon, San Blas, and Caledonia; on the south shore, Damas in the island of Coiba, the Bay of San Miguel, and Golfo Dulce. Gold, which in ancient times was obtained here in great quantities, is still found, and mines of salt, copper, iron, coal, &c., are worked. The climate is unhealthy, except in the interior and on the flanks of the mountains. Almost all the plants of the torrid zone may be raised here, but maize, rice, plantains, &c. (grown for the purpose of supplying the transit), are the chief crops. The imports amount annually to about £500,000, and the exports to the same value.—In 1855 a railway across the isthmus, from Aspinwall city on the Atlantic to Panama on the Pacific, was opened. The summit of the railway is 250 feet above the level of the sea; and the average value of the goods that annually pass over it is estimated at £11,000,000. The interoceanic canal promoted by M. Lesseps, also between Limon or Aspinwall and Panama, is in the main parallel to the railway. It is a level cutting, without locks, the cost being estimated at £33,000,000. Work was begun in 1881. The name, Isthmus of P., is generally used as interchangeable with Isthmus of Darien (q. v.).

PANATHENÆA, the most famous festival of Attica, celebrated at Athens in honour of Athene, patron goddess of the city, and intended to remind the people of Attica of their union into one community by the mythical Theseus. Before the time of Theseus, or—to speak more critically—before the formation of the Attic confederacy, this festival was only for the citizens of Athens, and was called simply *Athenæa*. According to tradition, the Athenæa owed its origin to King Erichthonius about 1506 or 1521 B.C. The later Panathenæa appears to have been a double festival. All writers who mention it, speak of a Lesser and Greater Panathenæa, the former held annually, the latter every fourth year. Both took place in the month *Hea-*

tombæon (July), and lasted several days. The Lesser Panathenæa was celebrated with gymnastic games, musical competitions, declamations, and a torch race in the evening, the whole concluding with the sacrifice of an ox. The prize of the victors was a vessel filled with oil from the sacred tree on the Acropolis. The Greater Panathenæa only differed from the Lesser in being more solemn and magnificent. Rhapsodists sang the Homeric poems; dramatic representations were given; and a splendid procession took place to the temple of Athene Polias, on the last day of the festival, to present the goddess with a *peplus* or embroidered robe, of crocus colour, woven by the maidens (*ergastinai*) of the city. Not alone the Athenians, but the whole population of Attica poured forth on this occasion. The procession is grandly sculptured on the frieze of the Parthenon by Phidias and his disciples.

PAN'AX. See GINSENG.

PAN'CAKE. This article of food is prepared by pouring a rich batter of flour, eggs, and milk into a frying-pan, so as to cover it about half an inch in thickness; the pan having been previously heated, and well supplied with butter, lard, or olive oil. A quick fire is necessary to cook it well, and when the under side is done, a dexterous cook by jerking the frying-pan manages to reverse the cake, so as to bring the upper side downward to be cooked in its turn. It is now a common practice to make pancakes rather smaller than the bottom of the pan, and frequently to add minced apples and other materials to vary and flavour them; these are, however, better known under the name of Fritters.

This dish is particularly associated with Shrove Tuesday, but the origin of the connection is by no means clear. Perhaps it is the relic of a heathen custom. The Saxons called February, *Solmonath*, 'which,' says a writer in *Notes and Queries* (First Series, vol. v. p. 491), 'Dr Frank Sayers, in his *Disquisitions*, says is explained by Bede, *Menais Placentarum*, and rendered by Spelman, in an inedited MS., "Pancake month," because, in the course of it, pancakes were offered by the pagan Saxons to the sun.'

PANCHATANTRA (literally, the five books) is the name of the celebrated Sanscrit fable-book of the Hindus whence the *Hitopadesa* (q. v.) was compiled and enlarged. Its authorship is ascribed to a Brahman of the name of Vishn'us'arman, who, as its introduction in a later recension relates, had undertaken to instruct, within six months, the unruly sons of Amaras'akti, a king of Mahil'aropya or Mihil'aropya, in all branches of knowledge required by a king, and for this purpose composed this work. If the latter part of this story be true, it is more probable, however, as Professor Benfey assumes, that Vishn'us'arman was merely the teacher of the princes, and that the existing work itself was composed by some other personage; for an older recension of the work does not speak of his having brought his tales into the shape of a work. The arrangement of the P. is quite similar to that of the *Hitopadesa*. The fables are narrated in prose, and the morals drawn from or connected with them are interwoven with the narrative in verse; many such verses, if not all, being quotations from older works.—On the history of the P., and its relation to the fable-books and fables of other nations, see the excellent work of Professor Theodor Benfey, *Panchatantra: fünf Bücher indischer Fabeln, Märchen und Erzählungen* (2 vols., Leip. 1859), the first volume containing his historical and critical researches on, and the latter

his literal translation into German of, the *Pan-chalantra*.

PANCREAS (from the Gr. *pan*, all, and *kreas*, flesh) is a conglomerate gland, lying transversely across the posterior wall of the abdomen, varying in

The under surface of the Stomach and Liver, which are raised to shew the Duodenum and Pancreas :

st, stomach; p, its pyloric end; l, liver; g, gall-bladder; d, duodenum, extending from the pyloric end of the stomach to the front, where the superior mesenteric artery (sm) crosses the intestines; pa, pancreas; sp, spleen; a, abdominal aorta.

length from 6 to 8 inches, having a breadth of about an inch and a half, and a thickness of from half an inch to an inch. Its usual weight is about three ounces. The head of the pancreas lies in the concavity of the duodenum.

The secretion of this gland, or the pancreatic fluid, is conveyed from its various parts by means of the pancreatic duct to the duodenum. This gland is found in all mammals, birds, reptiles, amphibians, and osseous fishes, and in some cartilaginous fishes.

The physical and chemical characters of the pancreatic fluid, and its uses in the animal economy, are sufficiently noticed in the article **DIGESTION**.

The diseases of the pancreas are few, and do not signify their existence by any very marked symptoms. The presence of undigested fat in the stools has been frequently observed in cases in which after death the pancreas has been found to be diseased; and if Bernard's views regarding the saponifying power of the pancreatic juice on fatty matters (described in the article already referred to) be correct, the reason why the fat should appear in the evacuations in these cases is sufficiently obvious. The most common form of disease is cancerous deposit in the head of the gland, which frequently induces jaundice by obstructing the common biliary duct near its opening. An accurate diagnosis of disease of this organ is extremely difficult, but fortunately is of comparatively little importance, as it cannot lead to efficient treatment; all that can be done in these cases being to palliate the most distressing symptoms.

The pancreas of ruminating animals is a favourite article of food under the name of sweetbread. That of the calf is most highly esteemed, but that of the lamb is often substituted for it. Dr Edward Smith questions whether the very high price often paid for calf's sweetbread is warranted by its nutritive qualities, or even by its flavour; although he allows that the flavour is perhaps the most delicate of any meat we are acquainted with. It is either boiled or fried. The thyroid and sublingual glands are also used as sweetbread.

PANCSOVA, an active trading town in the south of Hungary, inhabited by Servians and Germans, 70 miles S.S.W. of Temesvar, and close to the mouth of the Temes in the Danube, which is here a mile wide. It is a military station, contains

several churches, a high school, and a quarantine establishment. Silk spinning, brandy distilling, and an active trade with Servia in cattle, pigs, and corn, are carried on. Pop. (1880) 17,127.

PANDA (*Ailurus fulgens*), a quadruped of the family *Ursidæ* (see **BEAR**), a native of the Himalaya, the only known species of its genus, which has a very short muzzle, small rounded ears, a moderately long tail, covered with long hair, semi-retractile claws. The P. is about the size of a large cat. It dwells chiefly in trees, preying much on birds, but it also eats small quadrupeds and large insects. It has a thick, fine, woolly covering, adapting it to a cold climate, concealed by long, soft, glistening, and richly coloured hair, mostly chestnut brown, which passes into black on the sides and legs, and into white on the head. The P. is said to excel all other animals in the brilliancy of its fur, which, however, has not yet

Panda (*Ailurus fulgens*).

acquired any commercial value. The soles of the feet are thickly covered with woolly hair. The P. is also called *Wah* and *Chit-wa*, from a peculiar cry which it utters.

PANDANACEÆ, a natural order of endogenous plants, constituting a remarkable feature in the scenery of many tropical countries, but unknown in the colder regions of the globe. They are trees or bushes, often sending down adventitious roots, sometimes weak and decumbent, or climbing. There are two sections of the order, one (*Pandanææ*) including the genera *Pandanus*, *Freyinetia*, &c., having long, simple, imbricated leaves, usually spiny on the back and margin, their base embracing the stem, their spiral arrangement often notably visible; the other (*Cyclanthææ*) containing the genera *Cyclanthus*, *Nipa* (q. v.), *Carludovica*, *Phytelphas*, &c., having pinnate or fan-shaped leaves, and in general appearance much resembling palms, with which they have been often ranked. The two sections, however, are very similar in their flowers and fruit, in which they not a little resemble the humbler *Araceæ* and *Typhaceæ*. The flowers are mostly unisexual, naked, or with only a few scales, arranged on a spadix, and wholly covering it. The stamens are numerous; the ovaries usually clustered, one-celled, each crowned with a stigma; the fruit consists of fibrous, one-seeded drupes, collected or almost combined, or of berries with many seeds.—There are not quite 100 known species. Some are valuable for the fibre of their leaves, some for their edible fruit, &c. See **SCREW PINE**, **KIEKIE**, and **NIPA**. The unexpanded leaves of *Carludovica palmata* furnish the material of which *Panama hats* are made. The tree which

yields **VEGETABLE IVORY** (q. v.) is another of the palm-like section of this order.

PĀNDĀVAS, or the descendants of Pān'd'u (q. v.), is the name of the five princes whose contest for regal supremacy with their cousins, the Kurus, the sons of Dhṛitarāshṭra, forms the foundation of the narrative of the great epic poem, the *Mahābhārata* (q. v.). Their names are *Yudhisht'hira*, *Bhīma*, *Arjuna*, *Nakula*, and *Sahadeva*—the former three being the sons of Pān'd'u, by one of his wives, *Prithā*; and the latter two, by his other wife, *Mādrī*. But though Pān'd'u is thus the recognised father of these princes, the legend of the *Mahābhārata* looks upon him, in truth, merely as their father by courtesy; for it relates that *Yudhisht'hira* was the son of *Dharma*, the god of justice; *Bhīma*, of *Vāyu*, the god of wind; *Arjuna*, of *Indra*, the god of the firmament; and *Nakula* and *Sahadeva*, of the *As'vins*, the twin-sons of the sun.

PANDECTS (Gr. *Pandecton*, all receiving; from *pan*, all, and *dechomai*, I receive), one of the celebrated legislative works of the Emperor Justinian (q. v.), called also by the name *Digestum*, or *Digest*. It was an attempt to form a complete system of law from the authoritative commentaries of the jurists upon the laws of Rome. The compilation of the Pandect was undertaken after that great collection of the laws themselves which is known as the *Codex Justinianus*. It was intrusted to the celebrated *Tribonianus*, who had already distinguished himself in the preparation of the *Codex*. *Tribonianus* formed a commission consisting of 17 members, who were occupied from the year 529 till 533 in examining, selecting, compressing, and systematising the authorities, consisting of upwards of 2000 treatises, whose interpretation of the ancient laws of Rome was from that time forward to be adopted with the authority of law. A period of ten years had been allowed them for the completion of their work; but so diligently did they prosecute it, that it was completed in less than one-third of the allotted time; and some idea of its extent may be formed from the fact that it contains upwards of 9000 separate extracts, selected according to subjects from the 2000 treatises referred to above.

The Pandects are divided into 50 Books, and also into 7 Parts, which correspond respectively with Books 1—4, 5—11, 12—19, 20—27, 28—35, 36—44, and 45—50. Of these divisions, however, the latter (into Parts) is seldom attended to in citations. Each Book is subdivided into Titles, under which are arranged the extracts from the various jurists, who are 39 in number, and are by some called the classical jurists, although other writers on Roman law confine that appellation to five of the number, *Papinian*, *Paulus*, *Ulpian*, *Gaius* (q. v.), and *Modestinus*. The extracts from these indeed constitute the bulk of the collection; those from *Ulpian* alone making one-third of the whole work, those from *Paulus* one-sixth, and those from *Papinian* one-twelfth. Other writers besides these 39 are cited, but only indirectly, i. e., when cited by the jurists whose works form the basis of the collection. The principle upon which the internal arrangement of the extracts from individual writers was made had long been a subject of controversy. The question seems now to be satisfactorily solved; but the details of the discussion would carry us beyond the prescribed limits. Of the execution of the work, it may be said that although not free from repetition (the same extracts occurring under different heads), and from occasional inaptness of citation, and other inconsistencies, yet it deserves the very highest commendation. In its relations to the history and literature of ancient Rome it is invaluable; and

taken along with its necessary complement the *Codex*, it may justly be regarded (having been the basis of all the medieval legislation) as of the utmost value to the study of the principles not alone of Roman, but of all European law.

PANDŌRA (i. e., the 'All-endowed'), according to Grecian myth, was the first woman on the earth. When Prometheus had stolen fire from Jupiter, Zeus instigated Hephaestus to make woman out of earth to bring vexation upon man by her graces. The gods endowed her with every gift necessary for this purpose, beauty, boldness, cunning, &c.; and Zeus sent her to Epimetheus, the brother of Prometheus, who forgot his brother's warning against receiving any gift from Zeus. A later form of the myth represents P. as possessing a vessel or box filled with winged blessings, which mankind would have continued to enjoy if curiosity had not prompted her to open it, when all the blessings flew out, except Hope.

PANDOURS, a people of Servian origin who lived scattered among the mountains of Hungary, near the village of Pandour in the county of Sohl. The name used to be applied to that portion of the light-armed infantry in the Austrian service which is raised in the Slavonian districts on the Turkish frontier. The P. originally fought under the orders of their own proper chief, who was called *Harūn-Basha*, and rendered essential service to the Austrians during the Spanish War of Succession, and afterwards in the Seven Years' War. They originally fought after the fashion of the 'free lances,' and were a terror to the enemy whom they annoyed incessantly. Their appearance was exceedingly picturesque, being somewhat oriental in character, and their arms consisted of a musket, pistols, a Hungarian sabre, and two Turkish poniards. Their habits of brigandage and cruelty rendered them, however, as much a terror to the people they defended as to the enemy. Since 1750 they have been gradually put under a stricter discipline, and are now incorporated with the Austrian frontier regiments. The name is now obsolete.

PĀND'U, literally, 'white,' is the name of the father of the Pān'd'avas (q. v.), and the brother of Dhṛitarāshṭra. Although the elder of the two princes, he was rendered by his 'pallor'—implying, perhaps, a kind of disease—incapable of succession, and therefore obliged to relinquish his claim to his brother. He retired to the Himalaya Mountains, where his sons were born, and where he died. His renunciation of the throne became thus the cause of contest between the Pān'd'avas, his sons, and the Kurus, or the sons of Dhṛitarāshṭra.

PANEL (through Fr. from Lat. *pannus*, a piece

Panels.

of cloth, a patch), a space or compartment of a wall, ceiling, woodwork, &c., enclosed by beams, mouldings, framing, and so forth. It is generally sunk under the plane of the surrounding styles. In

woodwork, panels are thinner parts used to fill in strong framing, as in doors, shutters, &c. These are sometimes highly ornamented with tracery, shields, &c. (as in figs. 2 and 3). In late Gothic architecture, the panel is very often carved into the 'linen pattern' (fig. 1). Panelling is a style of ornament greatly used in Elizabethan architecture. The ceilings and walls are covered with it, and every piece of furniture is cut up into panels of every variety of form. Panels are said to be 'fielded' when the centre of the panel is raised with mouldings, &c.

PANEL (properly the alip or 'pane' of parchment on which the names of the jurors are written) is, in the practice of the English law, used to denote the body or set of jurors, consisting of 12 men, who try a cause, civil or criminal. In Scotch criminal law, the prisoner is usually called the panel.

PANGÉ LINGUA (Lat. 'Proclaim, O Tongue'), one of the most remarkable of the hymns of the Roman Breviary, and like its kindred hymn, *Lauda Sion*, a most characteristic example as well of the medieval Latin versification as of that union of theology with asceticism, which a large class of these hymns present. The Pangé Lingua is a hymn in honour of the Eucharist, and belongs to the service of the Festival of Corpus Christi. It is from the pen of the great angelic doctor, Thomas Aquinas (q. v.), and consists of six strophes of verses in alternate rhyme. Besides its place in the office of the Breviary, this hymn forms part of the service called Benediction with the Blessed Sacrament, and is sung on all occasions of the exposition, procession, and other public acts of Eucharistic worship.

PANGOLIN, or **PENGOLIN**, a name sometimes extended to all the species of *Manis* (q. v.), but originally belonging to *M. pentadactyla*, also called **SHORT-TAILED MANIS**, and in some parts of India **BAJGERKIT**; this species being a native of most parts of the East Indies, and P., its Malayan name, derived from a word which signifies to roll up; the animal having the habit of rolling itself up, on

Pangolin (*Manis pentadactyla*).

apprehension of danger, into a compact ball, the head in the centre, and its muscular mail-covered tail enfolding all. The food of the P. consists chiefly of ants, and like the rest of the genus, it is entirely destitute of teeth, and has a round, extensible tongue. Its claws are long and strong; it doubles them up like the American ant-eaters when it walks. It resides in burrows, which it excavates to the depth of seven or eight feet in the ground. It is capable of climbing trees, and the tail is prehensile. The whole length of the animal, including the tail, is almost five feet, the tail being not quite half the length of the body.

It is a gentle animal, easily tamed, and of an affectionate disposition.

PANIC is where fear, whether arising from an adequate or inadequate cause, obtains the mastery over every other consideration and motive, and urges to dastard extravagance, or hurries into danger, or death. An inexplicable sound causes a rush from a church, a vague report in the marketplace causes a run on a bank, and precipitate the very events that are dreaded. This emotion either differs from natural apprehension, or presents so intense and uncontrollable a form of the feeling, that it is propagable from one person to another, and involves alike the educated and ignorant—those who act from judgment as well as those who act from impulse. There are, besides this feature, several grounds for believing that such manifestations of involuntary terror are of morbid origin, and should be regarded as moral epidemics. They have generally arisen during, or have followed, seasons of scarcity and physical want and disease, the ravages of war, or periods of great religious fervour and superstition. The dancing mania, the retreat of the French army from Moscow, and recent and familiar commercial panics afford illustrations of certain of these relations. The most notable instance of universal panic, and that which demonstrates most aptly the connection here indicated, is the dread of the approaching end of the world which pervaded all minds, and almost broke up human society in the 10th century. The empire of Charlemagne had fallen to pieces; public misfortune and civil discord merged into misery and famine so extreme that cannibalism prevailed even in Paris; superstitious and vague predictions became formalised into a prophecy of the end of all things and universal doom in the year 1000. This expectation suspended even vengeance and war. The 'truce of God' was proclaimed, enormous riches were placed upon the altars. Worship and praise never ceased. The fields were left uncultivated; serfs were set free; four kings and thousands of nobles retired to the cloister; and all men, according to their tendencies, prepared to die.

It is worthy of note that during all pestilences there have arisen epidemic terrors, not so much of the devastations of disease, as of plots and poisonings directed by the rich against the poor. Even where these epidemic terrors are legitimately traceable to local and physical causes, as in the case of the singular affection timoria, which occurs in the marshy and unhealthy districts in Sardinia, the tremor and trepidation, and other phenomena, are ascribed to the magical influence of enemies. For the origin of the name, see **PAN**.

PANICLE, in Botany, a mode of inflorescence (q. v.) in which the floral axis is not only divided, but also subdivided more or less frequently. The panicle may thus be regarded as a Raceme (q. v.), of which the branches (or flower-stalks) are branched. The panicle is a very common kind of inflorescence. Most of the grasses exhibit it, and many other plants, both endogenous and exogenous. The common lilac affords a good example of it. The panicle, variously modified as to its form, and the arrangement and relative lengths of its branches and branchlets, becomes a Cyme (q. v.), Thyrsus (q. v.), &c.

PANICUM. See **MILLET**.

PĀNINI, the greatest known grammarian of ancient India, whose work on the Sanscrit language has up to the present day remained the standard of Sanscrit grammar. Its merits are so great, that P. was ranked among the Rishis (q. v.), or

inspired seers, and at a later period of Sanscrit literature, was supposed to have received the fundamental rules of his work from the god Śiva himself. Of the personal history of P., nothing positive is known, except that he was a native of the village Śālatura, situated north-west of Attock, on the Indus—whence he is also surnamed Śālāturiya—and that his mother was called Dākahl, wherefore, on his mother's side, he must have been a descendant of the celebrated family of Dakṣha. A tale-book, the *Kathāsaritsāgara* (i. e., the ocean for the rivers of tales), gives, indeed, some circumstantial account of the life and death of P.; but its narrative is so absurd, and the work itself of so modern a date—it was written in Cashmere, at the beginning of the 12th c.—that no credit whatever can be attached to the facts related by it, or to the inferences which modern scholars have drawn from them. According to the views expressed by Goldstücker (*Pānini, his Place, in Sanscrit Literature*: London, 1861), it is probable that P. lived before Śākyamuni, the founder of the Buddhist religion, whose death took place about 543 B.C., but that a more definite date of the great grammarian has but little chance of ascertainment in the actual condition of Sanscrit philology.—The grammar of P. consists of eight *Adhyāyas*, or books, each book comprising four *Pādas*, or chapters, and each chapter a number of *Sūtras* (q. v.), or aphoristical rules. The latter amount in the whole to 3996; but three, perhaps four, of them did not originally belong to the work of Pānini. The arrangement of these rules differs completely from what a European would expect in a grammatical work, for it is based on the principle of tracing linguistic phenomena, and not concerned in the classification of the linguistic material, according to the so-called parts of speech. A chapter, for instance, treating of a prolongation of vowels, will deal with such a fact wherever it occurs, be it in the formation of bases, or in conjugation, declension, composition, &c. The rules of conjugation, declension, &c., are, for the same reason, not to be met with in the same chapter or in the same order in which European grammars would teach them; nor would any single book or chapter, however apparently more systematically arranged—from a European point of view—such as the chapters on affixes or composition, suffice by itself to convey the full linguistic material concerned in it, apart from the rest of the work. In a general manner, P.'s work may therefore be called a natural history of the Sanscrit language, in the sense that it has the strict tendency of giving an accurate description of facts, instead of making such a description subservient to the theories according to which the linguistic material is usually distributed by European grammarians. Whatever objections may be raised against such an arrangement, the very fact of its differing from that in our grammars makes it peculiarly instructive to the European student, as it accustoms his mind to survey language from another point of view than that usually presented to him, and as it must induce him, too, to question the soundness of many linguistic theories now looked upon as axiomatic truths. As the method of P. requires in a student the power of combining many rules scattered all over the work, and of combining, also, many inferences to be drawn from these rules, it exercises, moreover, on the mind of the student an effect analogous to that which is supposed to be the peculiar advantage of the study of mathematics. The rules of P. were criticised and completed by Kātyāyana (q. v.), who, according to all probability, was the teacher, and therefore the contemporary, of Patanjali; and he, in his turn, was criticised by Patanjali (q. v.),

who sides frequently with Pānini. These three authors are the canonical triad of the grammarians of India; and their works are, in truth, so remarkable in their own department, that they exceed in literary merit nearly all, if not all, grammatical productions of other nations, so far as the two classes are comparable. The rules of P. were commented on by many authors. The best existing commentary on them is that called the *Kaśikā-vṛtti*, by Vāmana Jayāditya, which follows these rules in their original order. At a later period, attempts were made to arrange the rules of P. in a manner which approaches more to the European method; the chief work of this category is the *Siddhānta-Kaumudī*, by Bhaṭṭoji-dikṣita. P. mentions, in his *Sūtras*, several grammarians who preceded him, amongst others, Śākatāyana. Manuscripts of a grammar ascribed to a grammarian of this name exist in the Library of the India Office in London, and in the Library of the Board of Examiners at Madras. On the ground of a few pages only of the latter an attempt has been very recently made to prove that this grammar is the one referred to by P., and therefore older than the work of the latter. But the facts adduced in proof of this hypothesis are so ludicrously weak, and the reasoning upon them so feeble and inconclusive, whereas the evidence in favour of the comparatively recent date of this work is so strong, that no value whatever can be attached to this hasty hypothesis. For the present, therefore, P.'s work still remains the oldest existing grammatical work of India, and probably of the human race. The *Sūtras* of P., with a modern commentary by two native pandits, and with extracts from the *Vārtikas* of Kātyāyana and the *Mahābhāṣya* of Patanjali, were edited at Calcutta in 1809. This edition, together with the modern commentary, but with garbled extracts from the extracts mentioned, was reprinted at Bonn in 1839—1840 by Dr O. Boehtlingk, who added to it remarks of his own and some indices.—For the literature connected with P., see Colebrooke's preface to his *Grammar of the Sanscrit Language* (Calc. 1805), and Goldstücker's *Pānini*, &c., as mentioned above.

PANIPUT, the chief town of the district Kur-nal, in the division of Delhi, Punjab, is situated 54 miles (by road 78 miles) north by west from Delhi, in a fertile tract, the resources of which are largely developed by artificial irrigation. Pop. (1863) 25,276. Being a station on the great military road between Afghanistan and the Punjab, and to some extent an outpost of Delhi, it has been at various times the scene of strife between the inhabitants of India and invaders. The first great battle of P. was fought in 1526, and gained by Mirza Baber, the ex-ruler of Ferghana, at the head of 12,000 Mongols, over Ibrahim the emperor of Delhi, whose unwarlike array numbered 100,000 men, with 1000 elephants. This victory seated Baber on the throne of Hindustan as the first of the 'Great Mogul' dynasty. The second great battle was fought, in 1556, by the Mongols under Akbar, grandson of Baber, and third of the Mogul emperors, against Hemu, an Indian prince who had usurped the throne of Delhi. Hemu's army was defeated with great slaughter, and himself slain. The third battle was fought on the 14th of January 1761, between Ahmed Abdali, ruler of Afghanistan, and the till then invincible Mahrattas. The Jats, who had been forced to join the Mahrattas, deserted to the Afghans at a time when victory seemed to be declaring for the former; and this act of treachery, together with the loss of their leaders, threw the Mahrattas into confusion, and in spite of their most resolute valour they suffered a total defeat.

They left 50,000 slain on the field of battle, including all their leaders except Holkar, and 30,000 men were killed in the pursuit, which was continued for four days. The Mahrattas never recovered this crushing blow. It was at Kurnaul, a town a little to the north of P., that Nadir Shah of Persia, in 1739, won the celebrated battle over the Mogul emperor, which placed North-Western India at his feet.

PANIZZI, SIR ANTONIO, principal librarian of the British Museum from 1856 to 1866, was born on 16th Sept. 1797, at Brescello, in the *ci-devant* duchy of Modena. For his education he was sent first to the public school of Reggio, and afterwards to the university of Padua, where, in 1818, he took the degree of Doctor of Laws, with a view to practising at the bar. Early in life his sympathies were enlisted on behalf of the friends of Italy, as opposed to domestic tyranny and foreign intrusion, and when, in 1821, the popular revolution broke out in Piedmont, the young advocate became one of its leaders. The attempt, however, failed; and P., who had been denounced by a pretended friend, was arrested at Cremona. Having by some means contrived to escape, he took refuge in Lugano, and from thence in a short time found his way to Geneva. Meanwhile, during his absence, he was tried at home *per contumaciam*, as it is called, and sentenced to death, with confiscation of property. Nor was he allowed to remain at Geneva. The governments of Austria and Sardinia demanded from the Swiss Confederation the expulsion of all concerned in the recent outbreak, and among these P. was obliged to depart. Forbidden to pass through France, he reached England by way of Germany and the Netherlands. He now resided for about a month in London, whence he proceeded to Liverpool, with an introduction from Ugo Foscolo to Roscoe the historian, who received him with the utmost hospitality. At Liverpool, where he was introduced into the best circles by Mr Roscoe, he taught Italian, and continued to reside in that town until 1828, when he came to London again, and was chosen professor of Italian in the university of London, just then opened for students. In 1831, through the instrumentality of Lord Brougham, he was appointed one of the assistant-librarians in the British Museum; and upon the retirement of the Rev. Mr Baber, in 1837, from the office of Keeper of the Printed Books, P. was appointed his successor. In the previous year there had been a parliamentary committee on the state of the British Museum, before which P. gave valuable evidence, and likewise urged the adoption of measures for the improvement and augmentation of the library, which, upon becoming keeper, he was in a still better position to advocate. In 1838 he superintended the removal of the printed books from the old suite of rooms in Montague House to the new library; and in the same year, in conjunction with some of his assistants, he drew up the well-known 91 rules for the formation of a new catalogue of the library. These rules were approved by the trustees, and the first volume of a catalogue framed after them was printed and published in 1841. No other volume has been since published, and P., before a royal commission of inquiry into the Museum in 1847, justified the suspension of the printing until the whole catalogue should be finished. In 1845, P. drew up an elaborate report of the deficiencies existing in the library, in consequence of which the trustees applied to the Lords of the Treasury for 'an annual grant of £10,000 for some years to come, for the purchase of books of all descriptions.' This grant having been obtained, the library rapidly increased in numbers, to such a degree that in 1849 the books

amounted to 435,000, as compared with 235,000, the ascertained number in 1838. The number of volumes is now estimated at considerably over 1,000,000. Upon the resignation of Sir H. Ellis, in 1856, P. was appointed to the post of principal librarian of the British Museum. In a literary capacity, P. is known by his editions of Boiardo's *Orlando Innamorato*, and Ariosto's *Orlando Furioso* (1830-34), the minor poems of Boiardo (1835), and reprints of the first four editions of the *Divina Commedia* (1858). His pamphlet, *Chi era Francesco da Bologna*, proved the identity of the typefounder employed by Aldus, and the inventor of the well-known Aldine or Italic type, with the painter Francesco Francia. P. wrote occasional articles for the reviews. He retired on a pension in 1866, in 1869 received the order of K.C.B., and died 8th April 1879. He had the friendship of many of the most eminent men of his time. He had long maintained an active correspondence with Prosper Mérimée, whose letters have been published by Mr Fagan, P.'s unhappily having been burned during the Paris Commune. See L. Fagan's *Life of Sir A. P.* (2 vols. 1880).

PANJIM. See GOA.

PANNAH, or PUNNAH, a decayed town of India, in the district of Bundelcund, stands on the north-eastern slope of a plateau, 115 miles south-west of Allahabad. It was formerly a large, thriving, and well-built town; but whole streets are now desolate, or are tenanted only by monkeys, which, posted on the roof or at the windows, view the town's-people without alarm. The palace of the rajah is a beautiful building, surmounted by elegant kiosks, but is in many places ruinous. The source of the former prosperity of P. was its rich diamond mines. Owing to the diminished value of the gem, however, and the increased tax upon the produce of the mines, this branch of industry has much fallen off. The diamonds are generally tinted with colour; very few of them being of first-water, or completely colourless. This town is the chief place of a territory of the same name, which is bounded on the north by the British district of Banda, and on the south by the British district of Nerbudda. See BUNDELCUND.

PANNELS, in Artillery, are the carriages upon which mortars and their beds are conveyed on a march.

PANNO'NIA, a province of the ancient Roman empire, bounded on the N. and E. by the Danube, on the W. by the mountains of Noricum, and on the S. reaching a little way across the Save; and thus including part of modern Hungary, Slavonia, parts of Bosnia, of Croatia, and of Carniola, Styria, and Lower Austria. It received its name from the Pannonians, a race of doubtful origin, but who at first dwelt in the country between the Dalmatian Mountains and the Save, in modern Bosnia, and afterwards more to the south-east in Moesia. The Roman arms were first turned against them and their neighbours, the Iapydes, by Augustus in 35 B.C., and after the conquest of Segestica or Siscia (Siszek) he subdued them. An insurrection took place in 12 B.C., which Tiberius crushed after a long struggle; and a more formidable one of the Dalmatians and Pannonians together in 6 A.D., which was suppressed by Tiberius and Germanicus, but not till 8 A.D. Fifteen legions had to be assembled against the Pannonians, who mustered 200,000 warriors. Hereupon the Pannonians settled in the more northern countries, which received their name, and of which the former inhabitants, the Celtic Boii, had been in great part destroyed in Caesar's time. The country was now formed into a Roman

province, which was secured against the inroads of the Marcomanni and Quadi by the Danube, and on its other frontiers had a line of fortresses. Military roads were constructed by the conquerors, who also planted in the country many colonies and municipia, and thus gave it a rough coating of civilisation. Great numbers of the Pannonian youth were drafted into the Roman legions, and proved, when disciplined, among the bravest and most effective soldiers in the imperial army. P. was subsequently divided into Upper (or Western) and Lower (or Eastern) P., and under Galerius and Constantine underwent other changes. Upper Pannonia was the scene of the Marcomannic war in the 2d century. In the 5th c. it was transferred from the Western to the Eastern Empire, and afterwards given up to the Huns. After Attila's death, in 453, the Ostrogoths obtained possession of it. The Longobards under Alboin made themselves masters of it in 527, and relinquished it to the Avari upon commencing their expedition to Italy. Slavonian tribes also settled in the south. Charlemagne brought it under his sceptre. In the reigns of his successors, the Slavonians spread northward, and the country became a part of the great Moravian kingdom, till the Magyars or Hungarians took it in the end of the 9th century. In the time of the Romans, Siscia (Siszek), Vindobona (Vienna), Carnuntum (near Haimburg), and Arrabo (Raab) were among its principal towns.

PANORAMA (Gr. *pan*, all, *orama*, a view), a pictorial representation of the whole surrounding landscape as seen from one point. The invention of the panorama is claimed by the Germans for Professor Breisig of Danzig, but it does not appear that he ever constructed one. The real inventor was Mr Barker, an ingenious artist of Edinburgh, to whom the idea occurred while taking a sketch of the city from the top of Arthur Seat. After surmounting numerous difficulties—one of which was the invention of a new kind of perspective for the horizontal lines—he succeeded in producing an effective panoramic view of Edinburgh, which was exhibited in that city in 1788, and in London in the following year. The next panorama executed by Barker was a view of London from the top of the Albion Mills. A large building was now erected in Leicester Square for the exhibition of such views. On Mr Barker's death in 1806, he was succeeded by his son, in partnership with a pupil, Mr Burford, the painter of the chief modern panoramas. The first step in the construction of a panorama is to obtain sketches of the entire region to be represented; each sketch is a representation of a portion of the landscape in the form of a sector of a circle, with the sketcher's position as a centre, and the horizon for circumference. The canvas to which the sketches are to be transferred is hung round the sides of a circular room, and forms the surface of a cylinder, on the inside of which the panorama is painted. The canvas, brushes, &c., are of the finest description manufactured, and the painting and colouring are elaborated in the most careful manner, in order to render the optical illusion—which every one who has seen a good panorama must have experienced—as complete as possible. The stage from which the picture is viewed is placed in the centre of the room, about 30 feet on every side from the picture; the picture itself is fastened above to a strong circular hoop, and, hanging down, has its lower edge fastened to a similar hoop, which is heavily weighted to keep the picture steady. The light is admitted by an aperture in the roof, which is concealed by an awning from the spectators on the stage. Notwithstanding important defects in the panorama, one of which is

that the light more strongly illumines the upper than the lower parts of the picture—thus throwing the foreground comparatively into shade—many cases are on record of spectators being for the time completely under the influence of mental illusion. One of the best instances of this occurred during the exhibition of the third panorama in London. Part of the view consisted of a representation of the wreck of a ship's boat, with sailors struggling in the waves; and at sight of this, a dog belonging to one of the spectators at once leaped over the handrail to the rescue of the supposed drowning men. Panoramas, though frequently exhibited in France, Germany, and other European countries, have met with little success out of Great Britain. The most popular panorama ever executed was that of the Battle of Waterloo, the exhibition of which brought in ten thousand pounds. There are many modifications of the panorama, but that above described is the most important.

PANSLAVISM. This term is applied to the movement lately set on foot, and generally ascribed to Russian influence, for the amalgamation of all races of Slavonic descent into one body, having one language, one literature, and one social polity. The writings of Adam Gurowski and Kollar, and the anonymous pamphlet which appeared at Leipzig in 1837, under the title of *Die Europäische Pentarchie*, have exercised a very widespread influence in this direction among all the Slavonic people of the German states; and although the other nations of Europe have hitherto had no reason to anticipate any practical results from a movement towards Pan Slavism, the Slavonians of the Austrian empire have always taken occasion to shew that they regarded themselves as standing apart from German interests in times of public disturbance. Thus, in 1848, instead of taking part with their fellow-citizens in the election of representatives to the German parliament at Frankfurt, the leading promoters of Pan Slavism summoned a Slavonic congress at Prague, which was attended by Slavonians from Bohemia, Moravia, and Silesia, and by Slavonic Poles, Croats, Servians, and Dalmatians, who appeared in their national costumes. The impracticability of the grand schemes promulgated in the manifestoes of the conclave, had been sufficiently shewn ere the congress was interrupted by a democratic rebellion, which was suppressed with much bloodshed. Since 1860, when questions of nationality began to come more into the foreground, P. has exercised some direct influence on Austrian affairs: both northern and southern Slavs tending towards united action in opposition to the centralistic and dualistic aims of Germans and Magyars respectively. In 1867 a great Slavonic congress was held at Moscow without result. Pan Slavistic tendencies contributed to the great changes that took place in 1877-78 in the Balkan peninsula.

PANSY. See VIOLET.

PANTAGRAPH (Gr. *panta*, all, *graphein*, to delineate), an instrument by the aid of which any engraving may be copied on paper, though its use is in practice restricted to the copying of maps and plans. The copy can be drawn to any scale. The instrument consists of four rods, AB, AC, DF, and EF, jointed together, as in the figure; the points D and E are so taken that AD is equal to EF, and AE to DF, and consequently ADEF is always a parallelogram. If O be a determinate point near the end of the rod AE, and any line, CHB, be drawn cutting the other three rods, the triangles BAC and BDH are similar; so that when the point B is fixed, the points C and H, which can, from the structure of the instrument,

move in any direction, will describe similar figures different in size; that described by O being to that described by H in the proportion of OB to HB. The practical working of the instrument is as follows: The points H and B are determined by the ratio BH to BC, which is the proportion the scale of the copy bears to that of the original; a socket, which

slides along the arm, is fastened exactly at B on the under side; below this is placed a heavy weight, with a stalk fitting into the socket, thus rendering B the centre of motion of the instrument, if the weight be heavy enough. A pencil is fitted into another socket at H, and a rod of metal with a sharp point, called the *tracer*, is fastened at C, and the instrument is fitted with castors at various points underneath, to allow of its being moved freely. The operator then passes the tracer over the outline to be copied, and simultaneously the pencil at H makes the copy on the required scale. If a copy on a scale nearly as large as the original be required, the fulcrum must be placed in DF, and the pencil in DB; while if a magnified copy be required, the pencil and tracer must exchange the positions assigned them in the first case. The defects of this instrument are its weight and the difficulty of rendering it perfectly mobile, both of which prevent that steady motion of the tracer which is necessary for making an accurate copy.

To remedy these defects, the pantagraph has been constructed in a variety of forms, all of which, however, like the one described, depend upon the principle that the two triangles which have for their angular points, the fulcrum the pencil-point and a joint, and the fulcrum the tracer-point and a joint, must always preserve their similarity.

PANTELLARIA, a volcanic island in the Mediterranean, 36 miles in circumference, and lying 60 miles S.W. of the Sicilian coast. The chief products are wine, oil, cotton, and fruit.

PANTHAYS, a Mohammedan community occupying the province of Yun-nan in the south-west of China, who asserted their independence in 1855. In 1859 they captured Talifoo, the second city of the province, and in 1858, the capital. Their leader Wen-soai (King Suleiman) established his authority over about 4,000,000 of people, of whom not above a tenth were Mohammedans. In 1866 the Chinese government recognised the independence of the P., and in 1872 their king sent his son Hassan on a mission to Europe. Meanwhile the Chinese again attacked the P., defeated them utterly, and finally suppressed their empire. P. is an anglicised form of *Pan-si*, the name by which the Mohammedans called themselves.

PA'NTHEISM (Gr. *pan*, all, and *theos*, God), the name given to that system of speculation which, in its spiritual form, identifies the universe with God (*akosmism*), and in its more material form, God with the universe. It is only the latter kind of pantheism that is logically open to the accusation of Atheism (q.v.); the former has often been the expression of a profound religiosity. The antiquity of pantheism is undoubtedly great, for it is prevalent in the oldest known civilisation in the world—the Hindu. Yet it is a later development of thought than Polytheism (q.v.), the natural instinctive creed of primitive races, and most probably originated in the attempt to divest the popular system of its grosser features, and to give it a form that would satisfy the requirements of philosophical speculation. Hindu pantheism as *akosmism* is taught especially by the Upanishads (q.v.), the Vedānta (q.v.), and Yoga (q.v.) philosophies, and by those poetical works which embody the doctrines of these systems; for instance, the Bhagavadgītā, which follows the Yoga doctrine. It is poetical and religious, rather than scientific, at least in its phraseology; but it is substantially similar to the more logical forms developed in Europe. The Hindu thinker regards man as born into a world of illusions and entanglements, from which his great aim should be to deliver himself. Neither sense, nor reason, however, is capable of helping him; only through long continued, rigorous, and holy contemplation of the supreme unity (Brahma) can he become emancipated from the deceptive influence of phenomena, and fit to apprehend that he and they are alike but evanescent modes of existence assumed by that infinite, eternal, and unchangeable Spirit who is all in all. Hindu pantheism is thus purely spiritual in its character; matter and (finite) mind are both alike absorbed in the fathomless abyss of illimitable and absolute being.

Greek pantheism, though it doubtless originated in the same way as that of India, is at once more varied in its form, and more ratiocinative in its method of exposition. The philosophy of Anaximander (q.v.) the Milesian may almost, with equal accuracy, be described as a system of atheistic physics or of materialistic pantheism. Its leading idea is, that from the infinite or indeterminate (*to apeiron*), which is 'one yet all,' proceed the entire phenomena of the universe, and to it they return. Xenophanes (q.v.), however, the founder of the Eleatic school, and author of the famous metaphysical *mot*, *Ex nihilo, nihil fit*, is the first classical thinker who promulgated the higher or idealistic form of pantheism. Denying the possibility of creation, he argued that there exists only an eternal, infinite One or All, of which individual objects and existences are merely illusory modes of representation; but as Aristotle finely expresses it—and it is this last conception which gives to the pantheism of Xenophanes its distinctive character—'casting his eyes wistfully upon the whole heaven, he pronounced that unity to be *God*.' Heraclitus (q.v.), who flourished a century later, reverted to the material pantheism of the Ionic school, and appears to have held that the 'All' first arrives at consciousness in man, whereas Xenophanes attributed to the same universal entity, intelligence, and self-existence, denying it only personality. But it is often extremely difficult, if not impossible, to draw or to see the distinction between the pantheism of the earlier Greek philosophers and sheer atheism. In general, however, we may affirm that the pantheism of the Eleatic school was penetrated by a religious sentiment, and tended to absorb the world in God, while that of the Ionic school was thoroughly materialistic, tended to absorb God in the world,

and differed from atheism rather in name than in fact. But the most decided and the most spiritual representatives of this philosophy among the Greeks were the so-called 'Alexandrian' *Neo-Platonists* (q. v.), in whom we see clearly, for the first time, the influence of the East upon Greek thought. The doctrines of Emanation, of Ecstasy, expounded by Plotinus (q. v.) and Proclus (q. v.), no less than the fantastic Dæmonism of Iamblichus (q. v.), point to Persia and India as their birthplace, and in fact differ from the mystic teaching of the Vedanta only by being presented in a more logical and intelligible form, and divested of the peculiar mythological allusions in which the philosophy of the latter is sometimes dressed up.

During the middle ages, speculation was, for the most part, held in with tight reins by the church, and in consequence we hear little of pantheism. Almost the only philosopher who advocated, or who even seems to have thought about it, is John Scotus Erigena (see ERIGENA), who was probably led to it by his study of the Alexandrians, but his speculations do not appear to have been thought by him incompatible with a Christian faith; and in point of fact there are several profoundly mystical expressions employed in the New Testament, especially in the Epistles of John, in which the soaring spiritualism of Christianity culminates in language that has at least a pantheistic form; e. g., 'God is love; and he that dwelleth in love dwelleth in God, and God in him.' Erigena is regarded as the link that unites ancient and modern pantheism. We find in him now a reflection of the East and of Greece, and now a foreshadowing of the doctrines of Schelling and Hegel. His opinions were, with some scholastic modifications, introduced, in the 12th and 13th centuries, into theology by Amalric or Amaury de Chartres (a disciple also of Abelard), and his pupil David de Dinant, who were condemned as heretics by a council held at Paris.

Modern pantheism first shows itself in Giordano Bruno (q. v.), burned at Rome for his opinions in 1600. In Bruno reappear the speculations of the Eleatics and of the Neo-Platonists, but with a still more definite recognition than we meet with in them of an absolutely perfect supreme spirit. The universe, in the eyes of the unfortunate Italian, is not, properly speaking, a creation, but only an emanation of the Infinite mind—the eternal expression of its infinite activity; and hence the Infinite mind penetrates and fills, with different degrees of consciousness, all the heights and depths of the universe. To see God everywhere, to realise that He alone is, and that all else is but a perishable phenomenon or passing illusion—that there is but one intelligence in God, man, beast, and what we call matter—this should be the aim of all true philosophy. Spinoza (q. v.) comes next among pantheists in the order of time, but he is perhaps the greatest, certainly the most rigorous and precise of the whole class that either the ancient or the modern world has seen. His system is based, like the geometry of Euclid, on certain definitions and axioms, and he claims to have given it as conclusive and mathematical a demonstration as the latter. None will deny the keenness and cogency of his ratiocination. But human beings will not be forced into pantheistic convictions by any mere logical goad, however sharp; and the system, impregnable as it seems, has never had a formal adherent. The principal result at which, after a long, firm-linked chain of reasoning, Spinoza arrives, is, that there is but one substance, infinite, self-existent, eternal, necessary, simple, and indivisible, of which all else are but the modes. This substance is the self-existent God. To call Spinoza an atheist is ridi-

culous. The extravagant phrase of Schleiermacher, 'a God-intoxicated man' (*ein gott-trunkener mann*), would be greatly nearer the truth, for no human system of philosophy whatever exhibits such an all-controlling and even overwhelming sense of the omnipresent God. Many critics have said that he was far more of an old Hebrew in his system than he dreamed. Although he had no direct followers, he exercised great influence on the development of metaphysical speculation in Germany, where, with the exception of Kant (q. v.), the three greatest philosophers of recent times—Fichte (q. v.), Schelling (q. v.), and Hegel (q. v.)—have all promulgated systems of a thoroughly pantheistic and ideal character. Neither England, France, nor America has produced a single great pantheistic philosopher (unless Mr Emerson be regarded as such); but there is an immense amount of pantheistic sentiment floating about in the poetry, criticism, theology, and even in the speculative thinking, in these and all European countries in the present age. This is attributable to the ravages made by biblical criticism, and the progress of the physical sciences in the region of religious beliefs. Multitudes of men are puzzled what to think and what to believe. They do not like to face the fact that they have actually lost faith in revelation, and are no longer relying for help and guidance on the Spirit of God, but on the laws of nature; so they take refuge from the abhorred aspect of the naked truth that they are 'atheists' in a cloud of rose-coloured poetical phrases, which, if they mean anything, mean pantheism.

PANTHEON, a Greek or Roman temple dedicated to all the gods. The 'Pantheon' of Rome

Half Section of Pantheon (from Fergusson).

now the church of Santa Maria Rotonda, is the only ancient edifice in Rome that has been perfectly preserved. The P. is lighted through one aperture in the centre of its magnificent dome. It was erected by Agrippa, son-in-law of Augustus, 27 B.C.

PANTHER (*Felis pardus*), one of the largest *Felida*, now supposed to be identical with the Leopard (q. v.), or a mere variety of it, differing only in its larger size and deeper colour. Cuvier distin-

guishes the P. from the leopard, but without stating any characters other than those of colour. The

American Panther or Puma (*Felis concolor*).

name P. (vulg. 'Painter') is given to the Puma (q. v.) in America.

PANTHER, in Heraldry, is borne gardant, and incensed, i. e., with fire issuing from his mouth and ears.

PANTOMIME, among the ancient Romans, denoted not a spectacle but a person. The pantomimes were a class of actors who (as the name implies) acted not by speaking, but wholly by mimicry—gesture, movements, and posturings—corresponding therefore pretty closely to the modern ballet-dancers. When they first made their appearance in Rome cannot be ascertained; probably the *histriones* (Etrusc. *hister*, a dancer) brought from Etruria to Rome 364 B. C. were pantomimes; but the name does not once occur during the republic, though it is common enough from the very dawn of the empire. Augustus shewed great favour to this class of performers, and is consequently supposed by some writers to have been himself the inventor of the art of dumb acting. The most celebrated pantomimes of the Augustan age were Bathyllus (a freedman of Mæcenas), Pylades, and Hylas. The class soon spread over all Italy and the provinces, and became so popular with the Roman nobles and knights (who used to invite male and female performers to their houses to entertain their guests), that Tiberius reckoned it necessary to administer a check to their vanity, by issuing a decree forbidding the aristocracy to frequent their houses, or to be seen walking with them in the streets. Under Caligula they were again received into the imperial favour; and Nero, who carried every unworthy weakness and vice to the extremity of caricature, himself acted as a pantomime. From this period they enjoyed uninterrupted popularity as long as paganism held sway in the empire.

As the pantomimes wore masks, no facial mimicry was possible; everything depended on the movements of the body. It was the hands and fingers chiefly that spoke; hence the expressions, *manus loquacissima*, *digiti clamosi*, &c. To such perfection was this art carried, that it is said the pantomimes could give a finer and more precise expression to passion and action than the poets themselves. The subjects thus represented in dumb show were always mythological, and consequently pretty well known to the spectators. The dress of the actors was made to reveal, and not to conceal the beauties of their person; and as, after the 2d c., women began to appear in public as pantomimes, the effect, as

may easily be supposed, of the æsthetical costume was injurious to morality. Sometimes these pantomimic actresses even appeared quite naked before an audience—a thing which could never have happened had the Roman communities not become thoroughly base, sensual, and impure. It was quite natural, therefore, that pantomimic exhibitions should have been denounced by the early Christian writers, as they even were by pagan moralists like Juvenal.

Under **HARLEQUIN** is described the character of the modern pantomimes, which word denotes not the performers, but the pieces performed. A few additional facts are here given to complete that notice. The Christmas Pantomime, or Harlequinade, is, in its present shape, essentially a British entertainment, and was first introduced into this country by a dancing-master of Shrewsbury named Weaver, in 1702. One of his pantomimes, entitled *The Loves of Mars and Venus*, met with great success. The arrival, in the year 1717, in London of a troupe of French pantomimists with performing dogs gave an impetus to this kind of drama, which was further developed in 1758 by the arrival of the Grimaldi family, the head of which was a posture-master and dentist. Under the auspices of this family, the art of producing pantomimes was greatly cultivated, and the entertainment much relished. Joseph Grimaldi, the son of the dentist, was clever at inventing tricks and devising machinery, and *Mother Goose*, and others of his harlequinades, had an extended run. At that time the wit of the clown was the great feature; but by and by, as good clowns became scarce, other adjuncts were supplied, such as panoramas or dioramic views; and now the chief reliance of the manager is on scenic effects, large sums of money being lavished on the *mise en scene*. This is particularly the case as regards the transformation scene—i. e., the scene where the characters are changed into clown, harlequin, &c.—as much as £1000 being frequently spent on this one effort. In London alone, a sum of about £40,000 is annually expended at Christmas time on pantomimes. The *King of the Peacocks*, a pantomime produced at the London Lyceum Theatre during the management of Madame Vestris, cost upwards of £3000. Even provincial theatres, such as those of Manchester or Edinburgh, consider it right to go to considerable expense in the production of their Christmas pantomime.

PA'OLI, PASCAL, a famous Corsican patriot, was born in 1726, at Morosaglia, in Corsica. His father, having taken a leading part in the unsuccessful insurrection of the islanders against the Genoese and their French allies, was obliged to retire to Naples in 1739, taking his son with him. Here P. received an excellent education. In July 1755, he was summoned by the supreme magistracy to Corsica, and was elected captain-general of the island, and the chief of a democratic government, possessing all the power of a king, but without the title. He energetically and successfully applied himself to the reformation of the barbarous laws and customs of the island, and at the same time to the expulsion of the Genoese, who, notwithstanding the aid they received from an influential section of the islanders, were deprived of nearly all their strongholds, their fleet was defeated, and they were finally obliged to seek help from France. After the withdrawal of the French troops, they were again speedily deprived of the places they had recaptured, and in 1768 they ceded the island to France. P. refused all the advantageous offers by which the French government sought to bribe him, as he had before refused those of the Genoese, and continued to struggle for the independence of his country.

but he was signally defeated by the Comte de Vaux, at the head of the French troops, and the French became masters of the island. After one year's struggle, P. was compelled to take refuge on board of a British frigate, in which he sailed for England, where he was treated with general sympathy. Twenty years afterwards, the French revolution of 1789 recalled him to Corsica, and as a zealous republican he entered into the schemes of the revolutionary party; but during the anarchy of France in 1792—1793, he conceived a scheme for making Corsica an independent republic. Until this time he had been on the best terms with the Bonaparte family, but they now joined the Jacobin party whilst he allied himself with Britain, favoured the landing of 2000 British troops in the island in 1794, and joined them in driving out the French. He then surrendered the island to George III., but becoming dissatisfied with the government, he quarrelled with the British viceroy, whilst many of his countrymen were displeased with the course he had adopted in allying himself with the British. He therefore retired from the island in 1796, and spent the remainder of his life in the neighbourhood of London. P. died near London, February 6, 1807.

PAPA, a large market town in the west of Hungary, stands in a beautiful district on the Tapolca, an affluent of the Marczal, 60 miles south-south-east of Presburg. It contains a stately castle, with a beautiful garden, handsome Catholic and Lutheran churches, a Catholic gymnasium, Reformed college, and an hospital. Stoneware, cloth, and pipes are manufactured, and a trade in wine is carried on. Pop. (1880) 14,654.

PAPA, the Latin form of the title now, in the Western Church, given exclusively to the Bishop of Rome. Originally, however, meaning simply 'father,' it was given indiscriminately to all bishops. Tertullian (*De Pudicitia*, cxiii.) so employs it. Dionysius, a priest of Alexandria, calls his bishop Papa Heraclius. St Cyprian, in the letters of his clergy, is addressed *Beatissimo Papa Cypriano*. The same form is employed towards him by the clergy of Rome itself. Even Arius so addresses his own bishop Alexander. In the next century, St Jerome addresses the same title to Athanasius, to Epiphanius, and most of all to Augustine. Indeed it would appear certain that down to the time of Gregory of Tours it was used not uncommonly of bishops in the Western Church. And there are evidences of its being occasionally applied to the inferior clergy, for whom, however, some adjunct was employed, in order to distinguish them from bishops. Thus, we sometimes read of *papas pisinni*, minor popes; and the tonsure was called by the name *papa letra*. In the Greek Church, as is well known, whether in Greece Proper or in Russia, *papa* is the common appellation of the clergy. The circumstance of its having been originally of general application, is acknowledged by all learned Roman Catholic controversialists and historians.

PAPACY. See POPE.

PAPAL STATES (Italian, STATI DELLA CHIESA, or STATI PONTIFICI), a territory, or rather group of states in Central Italy, formerly united into one sovereignty, with the pope for its head. It was of an irregular form, resembling the letter Z, the upper portion lying to the east of the Apennines, the lower to the west of that range, these two being connected by a third strip, which crossed the peninsula from east to west. The P. S. were bounded on the N. by the Po, on the S. by Naples, on the E. by the Gulf of Venice and Naples, and on the W. by Modena, Tuscany, and the Tyrrhenian Sea.

Detached portions, as Benevento and Pontecorvo, lay within the Neapolitan territory. The country is traversed by the Apennines, which attain their highest elevation in the Monte della Sibilla, which is about 7402 feet above sea-level. Owing to this range, which traverses the peninsula in the direction of its length, lying so much nearer the east than the west coast, the streams to the east of it have a short course and little volume, being, in fact, mere mountain torrents; while on the west side a few of the rivers are of considerable size. Of the latter, the Tiber (q.v.) is the largest. The eastern coast is bold and rugged, and destitute of proper harbours, that of Ancona alone excepted; towards the north, at the mouth of the Po, it gradually subsides into a low, level, marshy tract, with numerous lagoons. The country west of the Apennines is traversed by ranges of hills parallel to them, and gradually decreasing in elevation as they approach the sea. The coast itself is almost wholly flat, sandy, or marshy, with no deep bays and few good harbours besides Civita Vecchia. There are numerous small lakes, principally in the northern portion of the country, the chief of which are Lake Bolsena, Lake Perugia, and Lake Bracciano, the last an old crater, situated almost 1000 feet above sea-level.

The country was divided into 20 districts: 1 Comarca, including Rome and the Agro Romano; 6 Legations, Bologna, Ferrara, Forlì, Ravenna, Urbino, Velletri; and 13 Delegations, Ancona, Ascoli, Benevento, Camerino, Civita Vecchia, Fermo, Frosinone, Macerata, Orvieto, Perugia, Spoleto, Rieti, Viterbo; with a total area in 1859 (the year before the disruption began) of 15,774 English square miles, and a population of above 3,000,000. The Legations of Bologna, Ferrara, Forlì, and Ravenna constituted the *Romagna*; Spoleto and Perugia were known as *Umbria*; and Ancona, Fermo, Macerata, and Ascoli constituted the *March of Ancona*. The inhabitants, with the exception of 16,000 Jews, were Italian, and Roman Catholics. The only provinces which latterly remained under the papal rule were, Rome with the Comarca, the legation of Velletri, and the delegations of Civita Vecchia, Frosinone (excepting Pontecorvo), and Viterbo, with a total area of 4493 English square miles, and a population of about 700,000. The chief cities and towns in the territory were, Rome (the capital), Viterbo, Velletri, Alatri, and Civita Vecchia.

Climate and Products.—The climate of the P. S. is one of the finest in the world, and the heat of summer is tempered by the mild and cooling sea-breezes; but in the flats south of the Po and in the Campagna of Rome, the noxious atmosphere produced by the exhalations from the marshes is most destructive of human life. Fever and ague are very prevalent among the inhabitants of the neighbouring districts, and notwithstanding the attempts to remedy the deadly influence of the marshes by drainage and cultivation, it has hitherto been undiminished (see MAREMMA). Violent siroccos are occasionally experienced on the west coast. The northern portion, from its elevation, is exposed to severe cold during winter. The soil of the P. S. is in general extremely fertile; but the higher mountain districts are either quite barren, or only adapted for pasture; and not more than one-third of the whole surface is under cultivation. The practice of agriculture is in its most primitive state, notwithstanding the fact that agriculture, as a science, originated here, and was practised for many centuries before it was introduced into the other countries of Europe; but the many political changes and revolutions which have convulsed the country, have acted as a bar to all

PAPAL STATES.

enterprise. It must, however, be mentioned, that the present pope has, by salutary enactments, and by the establishment of agricultural societies, done much for the improvement of this branch of industry. The products are similar to those of the rest of Italy. The manufactures are comparatively unimportant—silks, woollens, and leather are the chief; but plate-glass, rope, sailcloth, cotton goods, paper, artificial flowers, wax-candles, soap, stoneware, &c., are also manufactured in various places. The fisheries are important. The chief minerals are alum, vitriol, saltpetre, sulphur, coal, rock-salt, marble, and alabaster.

Many of the manufactured goods, and wine, olive oil, wool, hemp, tobacco, bread-stuffs, catgut, &c., were exported, the total exports amounting to about £2,600,000, while the imports reached nearly £14,000,000. The statistics were latterly very unreliable, but the fact that the P. S. are now no more, renders details of trade under pontifical rule a matter of little importance. Indeed, no information on such topics was issued under the latest years of the political power of the pope.

Government.—The pope possessed absolute and unlimited power, but the members of the college of cardinals, who elected him, generally kept the chief offices of state in their own hands, and assisted the pope in the government of his states, as well as in the affairs of the church. The secretary of state was at the head of political affairs, and was nominated by the pope. He presided over both the ministerial council and the council of state. The former council, which consisted of five or more ministers, heads of departments, selected by the pope, had a voice in legislation, and also the right of authoritative interpretation of the laws; the latter, which consisted of thirteen members, also nominated by the pope, had, in matters of legislation and finance only the right of giving advice; but it settled any question of competency that might arise between the various branches of the administration. After 1850, there was also a separate *finanz-consiglio* for the regulation of financial affairs. The Comarca, which was more directly under the central government, was ruled by a cardinal-president; the Legation was ruled by a cardinal-legate, aided by a provincial chamber of deputies. There were civil and criminal courts in all the provinces, minor courts in the communes, with courts of appeal in all the chief cities, and a central tribunal at Rome. All the proceedings of these courts were public, except trials for political offences.

The papal army, which formerly amounted to 20,000 men, in June 1863, numbered only 8513 men, infantry, cavalry, artillery, &c. included, and a considerable portion of the papal territory was garrisoned by French troops, without whose aid the pope's power could not have been maintained.

The income and expenditure for 1859, the last year of the entirety of the P. S., were respectively 14,453,325 scudi (£3,126,028), and 15,019,346 scudi (£3,248,038); but the three succeeding years shewed a widely different result; the expenses being largely increased by the cost of the war, while from the rebellious provinces scarcely any taxes were collected. The income and expenditure for these three years were nearly as follows:

	Expenditure.	Income.
1860	£4,730,809	£1,716,658
1861	4,391,644	1,716,658
1862	2,145,823	1,072,911

The finances continued in the same deplorable condition, and the national debt amounted to about £17,000,000. The tax known as 'Peter's pence,' which was collected from all the Roman Catholic

countries, had produced at the beginning of 1863 about £1,080,000.

History.—During the rule of the Goths and Lombards in Italy, the inhabitants of Rome and all who desired to live free from the barbarian yoke, feeling that the Greek empire was incapable of protecting them, and at the same time observing the pertinacity and energy with which the pope asserted the importance and dignity of Rome, naturally looked up to him as in some sort a protector; and it is to the gradual growth and spread of this feeling that the important position subsequently taken by the popes as authorities in temporal matters is chiefly due. About 720 A.D., Gregory III., having quarrelled with the Emperor Leo the Isaurian, declared the independence of Rome. In 726, Pepin le Bref compelled the Lombard king to hand over Ravenna, Rimini, Pesaro, Fano, Cesena, Urbino, Forlì, Comacchio, and fifteen other towns, to the pope, who now assumed the state of a temporal sovereign. Pepin's example was followed by his son Charlemagne; but, notwithstanding, the pope's sovereignty was more nominal than real, as the towns were not in his possession, and he only obtained a small share of their revenues. In the 11th c., the Normans greatly aided to increase the papal temporal authority, and in 1053 the duchy of Benevento was annexed. In 1102, the Countess Matilda of Tuscany left to the pope her fiefs of Parma, Mantua, Modena, and Tuscany; but these were immediately seized by the German emperor, and of this magnificent bequest only a few estates came into the pope's hands. Between this period and the end of the 13th c., the popes succeeded, often by unscrupulous means, in obtaining from many of the free towns of Italy an acknowledgment of the superiority of the Roman see over them; and in 1278 the Emperor Rodolf I. confirmed the popes in the acquisitions thus obtained, defined authoritatively the boundaries of the P. S., and acknowledged the pope's exclusive authority over them, by absolving their inhabitants from their oath of allegiance to the empire. The P. S. at this time included Perugia, Bologna, Bertinoro, the Duchy of Spoleto, the Exarchy of Ravenna, and the March of Ancona; but many of the towns were either republics or hereditary principalities, and in none did the pope possess real authority. Sixtus IV., in the end of the 15th c., managed to annex the Romagna to his dominions; in effecting which he is accused of having employed intrigue, perjury, and murder. His successors, Alexander VI. and Julius II., increased the P. S. by the addition of Pesaro, Rimini, Faenza, Parma, Placentia, and Reggio. By the victory of the French at Marignan (1515), the very existence of the papal power was threatened; but the able policy of Leo X. averted the threatened danger. In 1545, Paul III. alienated Parma and Placentia, and erected them into a duchy for his son, Pietro Luigi Farnese; but this loss was partly made up by the acquisitions of Gregory XIII. In 1598, the possessions of the House of Este, viz., Ferrara, Comacchio, and a part of the Romagna, were seized by Pope Clement VIII.; and the P. S. received their final additions in Urbino (1623), Ronciglione, and the duchy of Castro (1650). The Romagna was seized by Napoleon in 1797, and incorporated in the Cisalpine Republic; and in the following year, Rome was taken by the French, and the P. S. erected into the *Roman Republic*. Pius VII., in 1800, obtained possession of his states, but they were almost immediately retaken by the French, and finally (1809) incorporated with France, Rome being reckoned the second city of the empire. In 1814, the pope returned to his dominions, and was formally reinstated by the treaty of Vienna, mainly

through the exertions of the *non-Roman Catholic* powers, Russia, Prussia, and Britain; but the clerical misgovernment contrasted so strongly with the liberal administration of France, that in 1830 the people of Ancona and Bologna rose in rebellion. They were put down by the aid of an Austrian army, but the abuses in the administration were so flagrant, that even Austria urged the necessity for reform. Her remonstrances, however, were not attended to, and the Bolognese again rebelled. This second revolt supplied Austria with a pretext for occupying the northern Legations, and the French at the same time garrisoned Ancona. Occasional risings took place from time to time up to 1846, when the late pope, Pius IX., assumed the tiara, and burst upon the astonished world in the new character of a reforming pope. His projects were of a most liberal character, and were put in force with great energy, despite the opposition of Austria; but, alarmed at the spread of revolution in Europe during 1848, he halted in his career, just at the critical moment when to halt was to be lost. The people rose, and Pius IX. fled to Gaeta, whilst Rome was proclaimed a republic. He was restored, and his subjects reduced to submission, by the arms of France, Austria, Naples, and Spain. The Austrians held the Legations in subjection to the pope's authority till 1859; and the French occupied Rome in his behalf for ten years more. In July 1859, the four northern Legations (the Romagna), taking advantage of the withdrawal of the Austrian troops, quietly threw off the papal authority, and proclaimed their annexation to Sardinia, which was formally acknowledged by Victor Emmanuel in March 1860. The pope now raised a large body of troops, appointing Lamoricière, an eminent French general, to command them, for the purpose of resisting any further encroachments on his dominions; but the news of Garibaldi's success in Sicily and Naples produced revolt in the Legation of Urbino and in the Marches, the people proclaiming Victor Emmanuel. The Sardinians accordingly marched into the P. S., defeated Lamoricière in two encounters, and finally compelled him to retire into Ancona, where, after a siege of seven days, he was compelled to surrender with his whole army. The revolted provinces of Umbria, Urbino, and the Marches were immediately annexed to Sardinia; and the isolated provinces of Benevento and Pontecorvo (a part of Frosinone), which were situated within the kingdom of Naples, shared the same fate. In October 1870, the French having withdrawn, the remnant of the P. S. voted for annexation to the kingdom of Italy.

PAPAVERACEÆ, a natural order of exogenous plants, herbaceous or half shrubby, usually with a milky or coloured juice. The leaves are alternate, without stipules; the flowers on long one-flowered stalks. The fruit is pod-shaped or capsular; the seeds numerous. The order is distinguished for narcotic properties. Opium (q. v.) is its most important product. The juice of *Celandine* (q. v.) is very acrid. A number of species are used in their native countries for medicinal purposes. The seeds yield fixed oil, which, with the exception of that obtained from *Argemone Mexicana*, is quite bland. See **POPPY**. The flowers of many species are large and showy, most frequently white or yellow, sometimes red. Several kinds of Poppy and *Eschscholtzia* are frequent in our gardens. There are in all about 130 known species, natives of all quarters of the world, and of tropical and temperate climates, but they abound most of all in Europe.

PAPAW' (*Carica Papaya*), a South American tree of the natural order *Papayaceæ*—of which

order about 30 species are known—which has now been introduced into many tropical and subtropical countries. It grows to the height of 15–30 feet, with leaves only at the top, where also the fruit grows close to the stem. The leaves are 20–30 inches long. The fruit is of a green colour, very similar in appearance to a small melon, and with a somewhat similar flavour. It is eaten either raw or boiled. The seeds are round and black, and when chewed, have in a high degree the pungency of cresses. The powdered seeds and the juice of the unripe fruit are most powerful anthelmintics. A constituent of this juice is *Fibrine*, otherwise unknown in the vegetable kingdom, except in the Fungi. The milky juice of the tree is very acrid. The leaves are used by negroes instead of soap to wash linen. The juice of the fruit and the sap of the tree have the singular property of rendering the toughest meat tender in a short time. Even

Papaw Tree (*Carica Papaya*).

the exhalations from the tree have this property; and joints of meat, fowls, &c., are hung among its branches to prepare them for the table. It is a tree of extremely rapid growth, bears fruit all the year, and is exceedingly prolific. The fruit is often cooked in various ways.—The *Chamburu* (*C. digitata*), another species of the same genus, a native of Brazil, is remarkable for the extremely acrid and poisonous character of its juice, and the disgusting stercoraceous odour of its flowers.—In the middle and southern states of America the name *P.* is given to the *Uvaria* (or *Asimina triloba*, a small tree of the natural order *Anonaceæ*, the fruit of which, a large oval berry, three inches long, is eaten by negroes, but not generally relished by others. All parts of the plant have a rank smell.

PA'PENBURG, a small town of Hanover, in the bailiwick of Osnabrück, on a canal navigable for sea-going vessels, 27 miles south-south-east of Emden, on Dollart Bay, by the Emden and Hanover Railway. It originated in a small colony which sprung up here, and was supported principally by peat-cutting, an employment for which the fens and moors of the vicinity afford abundant facilities. The town is cleanly built, after the Dutch model; its houses stretch along the canal banks. It possessed, in 1881, about 190 ships, and carries on manufactures of

sail-cloth and ropes. Its commerce is considerable. Pop. (1830) 6736.

PAPER. This well-known fabric is usually composed of vegetable fibres minutely divided and recombined in thin sheets, either by simple drying in contact, or with the addition of size or some other adhesive material. Probably the earliest use of paper was for the purpose of writing upon, and its earliest form was the Papyrus (q. v.) of the Egyptians. The stems of the papyrus plant, which are often eight or ten feet long, are soft and green, externally like the common rush; and the interior consists of a compact cellular tissue or pith. At the bottom of each stem the portion immersed in the mud and water is whiter and more compact; and under the outer skin a number of thin pellicles lie one above the other. These were removed, and laid side by side with their edges overlapping each other, and crosswise upon these was placed one or more similar layers, until the sheet was sufficiently thick; pressure was then applied for a time, and afterwards the sheet was dried in the sun. The width of such sheets, of course, depended upon the length of the portion of papyrus stems taken; but they could be made any length by joining a number of the squares end to end by glue or any other adhesive material. The *scapus*, or roll, usually consisted of about 20 of them.

Owing to the fact that the various layers of the papyrus decrease in thickness as they are nearer to the centre of the stem, the makers were enabled to produce papers of different qualities; and in the time of the Romans many varieties were known, which differed as to the quality of the material, and the size of the pieces of which the sheets were composed. The finest quality was made from the innermost layer of membrane, and was called *Hieratica*, or paper of the priests. This was made for the Egyptian priests, who interdicted its sale until covered with sacred writing. In this state it was, however, an article of trade, and the Romans found a means of removing the writing, and sold the palimpsest sheets in Rome under the name of *Augustus* paper, used as a Latin equivalent for its former Greek name of *hieratica*. It was, however, supposed by many that it was named after the Emperor Augustus, and in consequence a second quality was called after his wife, *Livinia*; and the original name of the first quality came in time to be applied to the third quality. The next quality was called *Amphitheatrica*, it is supposed, from its having been made in the vicinity of the Alexandrian amphitheatre. This last, when imported to Rome, was partly remanufactured by Q. Remmius Fannius Palemon, the schoolmaster and paper-maker, who, by a peculiar process of his own, reduced its thickness, and rendered it equal to the first quality, when it was sold under the name of *Fanniana*. There were other inferior qualities, of which one called *Emporetica* was used as shop-paper.

Pliny, from whom we get these very interesting particulars, tells us that all these kinds were manufactured in Egypt, and required the Nile water for their formation. He says, that 'when it is in a muddy state it has the peculiar qualities of glue, and the various kinds of paper are made on a table where they are moistened with this water. The leaves or sheets of membrane are laid upon it lengthwise, as long indeed as the papyrus will admit of, the jagged edges being cut off at either end; after which a cross layer is placed over: the same way, in fact, that hurdles are made. When this is done, the leaves are pressed together, and dried in the sun.' The idea of the adhesive quality of the Nile water is erroneous, but it is very probable the Egyptian manufacturers encouraged the error.

It is obvious the whole merit consisted in using the membranes fresh, whilst their own natural gum was in proper condition to make them adhere together.

In India and China, the art of writing with a style or sharp point upon dried palm and other leaves, and also some kinds of bark, is common even at the present day, especially in Ceylon, where we find it common to employ the leaves of the talipot and other palms as paper. Perhaps it was from the employment of these materials, or it is even possible from watching the operations of the paper-making wasps and other insects, that the manufacture of larger pieces, by pulping the materials and spreading them out to a greater extent, was suggested. Whatever was the true origin of the art, it is now lost in the vista of time.

It is known that the Chinese were acquainted with the art of making paper from pulp artificially prepared as early as the commencement of the Christian era; and it is thought that they used the bark of various trees, the soft parts of bamboo stems, and cotton. In the 7th c., the Arabians learned the art of making it of cotton from the Chinese, and the first manufactory was established, about 706 A.D., at Samarcand. From thence it was transplanted to Spain, where, under the Moors, paper was made not only of cotton, but it is thought also of hemp and flax. The exact time of the introduction of paper made of linen rags is very uncertain; but the best evidence is offered by the Arabian physician Abdollatiph, who writes, in an account of his visit to Egypt in the year 1200, 'that the cloth found in the catacombs, and used to envelop mummies, was made into garments, or sold to the scribes to make paper for shopkeepers;' and as there is no doubt that these mummy-cloths were linen, it proves that the use of this material is of no mean antiquity. Of the use of linen rags in Europe, the earliest proof is in the celebrated document found by Ichwandner in the monastery of Goss, in Upper Styria, which purports to be a mandate of Frederick II., emperor of the Romans, and is dated 1242. It is written on paper which has been proved to be made of linen. The practice of making a distinctive water-mark on the paper, by means of an impression on the fine sieve of threads or wires upon which the floating pulp is received (fig. 4), was also of very early date, as MSS. as old as the 13th c. bear it. But there is really no satisfactory information respecting the exact time or place of the introduction of paper-making into Europe; by some it is supposed that Spain was the first to receive the art, and that thence it spread to France and Holland, and afterwards to England. It is quite certain that England was a long time behind these countries. As a proof of this, we find that the first patent for paper-making was taken out in 1665, by one Charles Hildeyard, but it was for 'The way and art of making blew paper used by sugar-bakers and others.' The second was in 1675, by Eustace Barneby, for 'The art and skill of making all sorts of white paper for the use of writing and printing, being a new manufacture, and never practised in any way in any of our kingdoms or dominions.' This, then, was the first commencement of the making of writing and printing paper; but that it did not equal the manufactures of other countries is shewn by the specification of another patent, taken out by John Briscoe in the year 1685, which is thus expressed: 'The true art and way for making English paper for writing, printing, and other uses, both as good and as serviceable in all respects, and especially as white as any French or Dutch paper.' As a general rule, it was the custom of paper-makers to employ linen rags for fine papers, but a great variety of other materials have been in use

PAPER.

from its first introduction; for, as early as 1690, Nathaniel Bladen took out a patent for 'An engine method and mill, whereby hemp, flax, linnen, cotton, cordage, silke, woollen, and all sorts of materials' might be made into paper and paste-board; and from that time innumerable efforts have been made to prepare other materials than cotton and linen rags for the manufacture of paper. The following is a summary of the patents which have been taken out in Britain for making paper from various materials, with the dates, which will shew to those engaged in this investigation in what directions the inquiry has been previously conducted. The arrangement is alphabetical, and consequently not in the order of dates.

Materials.	Names of Inventors, and Dates of Patents.
Aloe Fibre, . . .	Berry, 1838; D'Harcourt, 1838; Small, 1838; May, 1852; Burke, 1855.
Asbestos, . . .	Maniere, 1853.
Bagging or Sacking, . . .	Stiff, 1853; Wheeler and Co., 1854; Roester and Co., 1854; Smith and Co., 1855.
Banana Fibre, . . .	Berry, 1838; Ldly, 1854; Jullion, 1855; Burke, 1855; Hook, 1857.
Barks of various kinds, . . .	Koops, 1800; Balmano, 1838; Nerot, 1846; Couplier, 1853; Johnson, 1855; Kelk, 1855; Lotteri, 1855; Niven, 1856; Broad, 1857; Hope and Co., 1857.
Bass or Bast, . . .	Ruck and Touche, 1856; Touche, 1857.
Bean-stalks, &c., . . .	D'Harcourt, 1838; Brooman, 1856.
Cane (Sugar), . . .	Berry, 1838; Couplier, 1852; Johnson, 1855; Jullion, 1855; Ruck and Touche, 1856; Hook, 1857.
Cocoa-nut Fibre, . . .	Newton, 1852; Holt and Forster, 1854.
Cocoa-nut Kernel, . . .	Diaper, 1854.
Clover, . . .	Coupland, 1854; Holt and Fraser, 1854; Plunkett, 1857.
Cotton, . . .	Bladen, 1692; Williams, 1833; Couplier, 1852; Crossley, 1854; Siblet, 1857.
Dung, . . .	Jones, 1805; Zander, 1839; Lloyd, 1852; Hill, 1854.
Esparto or Alfa, . . .	Routledge, 1856.
Flax, . . .	Bladen, 1692; Koops, 1800; Jones, 1805; Ball, 1817; Berry, 1838; Gibbs, 1833; De la Garde, 1825; Couplier, 1852; Collins, 1853; Pownal, 1852; Coupland, 1854; Broad, 1857.
Flax, New Zealand, . . .	Berry, 1838; Gibbs, 1833 and 1857; Gillman, 1854.
Fresh-water Weeds, . . .	Archer, 1855.
Fur, . . .	Williams, 1832.
Grasses, . . .	Stiff, 1853; Evans, 1854; Clift, 1854; Coupland, 1854; Jeyes, 1854; Crossley, 1854; Jackson, 1854; Johnson, 1855; Fraser, 1855; Gilbee, 1855; Holt and Fraser, 1854; Pariset, 1856.
Gutta-percha, . . .	Hancock, 1846.
Hair, . . .	Williams, 1832.
Hay, . . .	Koops, 1800; Castelain, 1854; Pariset, 1856.
Heath, . . .	Crossley, 1854.
Hemp, . . .	Bladen, 1692; Hooper, 1790; Koops, 1800; De la Garde, 1825; Gibbs, 1833; Couplier, 1852; Collins, 1853; Barguano, 1853; Jackson, 1854; Helin, 1854; Broad, 1857; Ball, 1817.
Hops and Hop-lines, . . .	De la Garde, 1825; D'Harcourt, 1838; Balmano, 1838; M'Guaran, 1839; Sheldon, 1843; Barling, 1854; Crossley, 1854; Holt and Fraser, 1854; Taylor, 1854; Broad, 1857; Plunkett, 1857.
Husks of Grain, . . .	Wilkinson, 1852.
Jute, . . .	Calvert, 1846; Nerot, 1846; Couplier, 1852; Helin, 1854; Jackson, 1854; Smith and Hollingworth, 1856.
Leather, . . .	Hooper, 1790; Trappe, 1854; Ooks, 1856; Van den Hout, 1856; Lichtenstadt, 1857.
Leaves, . . .	Balmano, 1838; Warner, 1853; Vivien, 1853; Johnson, 1855; Moll, 1855; Ruck and Touche, 1857.

Materials.	Names of Inventors, and Dates of Patents.
Maize, Husk, and Stems, . . .	D'Harcourt, 1838; Balmano, 1838; Ruck and Touche, 1857.
Manilla Hemp or Plantain Fibre, . . .	Newton, 1852.
Moss, . . .	Nesbitt, 1834; Bellford, 1854; Johnson, 1855.
Nettles, . . .	Jones, 1805; De la Garde, 1825; Clift, 1854.
Old Writing Paper, . . .	Koops, 1800.
Pea Stalk, . . .	D'Harcourt, 1838.
Peat or Turf, . . .	Ley, 1852; Clarke, 1853; Lallemande, 1853; Crossley, 1854; Hemming, 1857; Westerman, 1852.
Roots of various kinds, . . .	Balmano, 1838; De la Bortoehe, 1855; Johnson, 1855; Ackland, 1854; Barling, 1855; Dubus, 1857.
Sawdust, . . .	Wilkinson, 1852; Johnson, 1855.
Sea-weeds, . . .	Martenoll de Martonell, 1855; Archer, 1855.
Silk, . . .	Bladen, 1692; Bull, 1817; Williams, 1832.
Straw, . . .	Koops, 1800; Lambert, 1824; Zander, 1839; Couplier, 1852; Stiff, 1853; Poole, 1853; Helin, 1854; Fraser, 1855; Chanchard, 1856; Castelain, 1854; Broad, 1857; Wheeler, 1857.
Tan (Spent Bark), . . .	Crossley, 1854; Jeyes, 1854; Holt and Forster, 1854; Horton, 1855; Roester and Bishop, 1854.
Thistle-down, . . .	Bellford, 1854.
Thistles, . . .	Koops, 1800; Lord Berridale, 1854; Lalle, 1854.
Tobacco-stalks, . . .	Adcock, 1854.
Wood, . . .	Koops, 1801; Desgrand, 1838; Brooman, 1853; Swindells, 1854; Newton, 1855; Johnson, 1855; Kelk, 1855; Martin, 1855; Pradeval, 1855; De Frontur, 1855; Chanchard, 1856; Amyot, 1856; Newton (Voelter), 1857; Poiset, 1857; Couplier, 1852.
Wool, . . .	Bladen, 1692; Williams, 1832; Dickenson, 1807; Crossley, 1854.
Wrack Grass or Zostera, . . .	Spooner, 1857.

But whatever the material employed, the process for nearly all is the same. The rags, bark, fibres, or other substance, have to be reduced with water into a fine smooth pulp. This, in the early stages of the manufacture, was accomplished by macerating and boiling the material, until, in the case of bark, fibres, or other raw material, the fibres could be drawn out from the cellulose matter, after which it was beaten with mallets, or with pestles in mortars, or stampers moved by some power. Water is generally used, but in Holland wind-mills do this work. The beating is continued until the material is reduced to a very smooth pulp. The pulping, in our machine paper-mills, is much more rapidly accomplished by boiling the linen or cotton rags, or other material, in a strong lye of caustic alkali. This effectually cleans the rags, and other vegetable fibres

Fig. 1

are softened and separated in a remarkable manner by it; they are then put into a machine called the washing-machine (fig. 1), which washes out dirt

and everything but the pure vegetable fibre. This machine (figs. 1, 2, and 3) is a large cast-iron vessel, usually about 10 feet in length, 4½ feet in width, and 2½ feet in depth. In the middle, occupying about two-thirds of its length, is a partition, always cast with it, called the mid-feather, *a* (figs. 1 and 2), to support the axle or driving-shaft, *b*

Fig. 2.

(figs. 1 and 2). This turns the cylinder *c* (fig. 1), which has a large number of teeth or ridges running across it, which grip and tear the rags, or other materials, as they are drawn under it by the current formed by its revolutions. In order to facilitate this, a peculiar form is given to the bottom of the part in which the cylinder works, as seen in fig. 3. The rise, *a* (fig. 3), is called the back-fall, and the

Fig. 3.

materials are drawn up to, and through the narrow space at *b*, by the current; then, as they pass over the ridged surface, *c*, they come in contact with the ridged surface of the cylinder, and are thus violently ground and drawn through, the stream carrying them round and round until they are thoroughly washed and partly pulped; or, as it is technically called, *broken in*. The washing-machine is supplied with a continued flow of clean water, and the soiled water as regularly escapes through a fine gauze screen, in the ends of the cylinders, in which is an ingenious arrangement for raising it and carrying it away through the axis, which is hollow. The contents of the washing-machine are then allowed to flow out through a large valve, opening downwards into the draining-chest. Here the water is drained away, and the *stuff* is then placed in the bleaching vats, which are made of stone, and each calculated to contain a hundredweight of stuff, which is here submitted to the action of a strong solution of chloride of lime for about twenty-four hours, and frequently agitated; after which it is transferred to a hydraulic press, and pressed so as to remove the greater portion of the liquid and chloride of lime. It is then placed in another washing-engine, and for

an hour is submitted to the same process as in the first; by which all vestiges of the bleaching materials are removed, and the stuff so much more broken down as to be called *half-stuff*. From this engine it is let out by a valve, and finds its way into the *beating-engine*, which is placed at a lower level so as to receive it. Here the arrangement is nearly the same as in the washing and intermediate engines; but the ridges on the bars below the cylinder, and on the cylinder itself, are much sharper, and the disintegration of the fibres is carried on with great rapidity until they are quite separated; and the flow of the water in a rapid current, as it passes the cylinder, draws them out and arranges them in the water in much the same way as wool or cotton is laid on the carding-cylinders of a carding-machine. This operation takes about five hours, at the end of which time the materials have been worked up with the water into an almost impalpable pulp. This is then let out into the pulp vat, where it is kept continually agitated by a wooden wheel revolving in it, called a *hog*, and from this the hand-workman or machine is supplied.

We will now suppose the pulp formed and ready for use in the vat, and will first describe the process of hand-making, as formerly practised in all countries, and still in use, more or less, in all paper-making countries. The workman or vatman

takes an implement called a *mould*, which consists of a sheet of very fine network, attached to a frame, as in fig. 4. In Europe, this network was always made of very fine wire; but in India, China, and Japan it is usually made of

Fig. 4.

fine fibres of bamboo, which the workmen of these countries split and weave with remarkable skill. There are usually two kinds of moulds employed. In one, as in fig. 4, the wires are woven across each other, forming a very fine gauze, and paper made with them is known as *woove*. In the other, there are several cross-bars in the frame, and straight wires are laid from side to side, and about four or five to each half sheet are laid across them lengthwise, to keep them in position; the transverse wires are about twenty to the inch; the longitudinal ones are a little more than an inch apart. Paper made on such moulds is called *laid*, and is easily known by the impression of the wires upon it. Whichever

kind of mould is used, another implement called the *deckle* (fig. 5) is required. It is a thin frame, which exactly corresponds to

Fig. 5.

the frame of the mould, and the workman first places the deckle on the mould, and then dips them into the pulp; the deckle forms a ridge which retains just enough of the liquid pulp for the sheet of paper. The water of the pulp speedily drains through the wire gauze, and after it has stood in an inclined position for a few minutes, another workman, called the *coucher*, applies the

face of the sheet of pulp to a piece of felt or flannel cloth stretched on a board, called the *couch*, and the sheet thus pressed, leaves the mould, and is left on the *couch*. Every successive sheet is similarly treated, and they are piled one on another, with a sheet of felt between each, until from four to eight quires, or a *post*, as it is called, is formed. Each post is put in a press, and under pressure parts with nearly all the moisture in the sheets of paper. The felts are then removed, and after several pressings, and other minor operations, the paper is hung on hair ropes, called *tribles*, in the drying-loft; and when dried, resembles blotting-paper, and cannot be written upon. This is remedied by dipping it in a weak solution of hot size, sometimes tinged with colour, after which it is pressed, dried, folded, and made up into quires. Hot pressing and glazing are done by passing the sheets through hot and polished iron rollers.

In Britain very little paper is now made by hand, the paper-machine having changed the character of the manufacture. It is usually stated that Louis Robert, a Frenchman, invented the paper-machine, and that it was brought to this country by Didot of Paris in an imperfect state, but received improvements from Fourdrinier. But it must not be overlooked that Bramah took out a patent in 1805, rather more than a year before Fourdrinier, for very similar improvements to those described in Fourdrinier's specification. The object of all was to cause an equal supply of the pulp to flow upon an endless wire-gauze apron, which would revolve and carry on the paper until it is received on an endless sheet of felt, passing around and between large couching cylinders. These machines have now been brought to such perfection, that paper can be made in one continuous web of any length; and before leaving the machine, is sized, dried, calendered, hot-pressed, and cut into sheets. Different engineers have contrived variations of construction in the paper-machine, but the general principles of all are the same. We therefore select for illustration the machine which was exhibited by Mr George Bertram of Edinburgh, and which was universally acknowledged to be by far the most complete and perfect which was presented in the International Exhibition of 1862. Since then no very important improvements have been made in the main part of the machine, but the drying portion has been greatly extended.

Fig. 6 is a side view of the machine, and fig. 7 a vertical one. The principle of the machine is very simple; it contains a pulp vat, A (figs. 6 and 7), with a hog or wheel inside to agitate the pulp, and an arrangement for pouring the pulp over the wire-gauze mould, B, B, B, B, which instead of being in single squares, as in the hand-process, is an endless sheet moving round two rollers, *a, b*, which keep it stretched out and revolving when in operation. Under the part which receives the pulp there is a series of small brass rollers, *d* (fig. 6), these, being nearly close together, keep it perfectly level, which is a most necessary condition; besides which, there is a shallow trough, *ee* (fig. 6), called the *save all*, which catches and retains the water, which always escapes with some pulp in suspension; and an arrangement of suction boxes and tubes, *f, f, f* (fig. 6), worked by air-pumps, which draw much of the water out as the pulp passes over them. The pulp is kept from running over the sides by straps called the *deckles*, which are also endless bands, usually of vulcanised India-rubber, carried round moving rollers, so that they travel with the wire-gauze, and therefore offer no resistance to it. In addition to all this, the framework on which the surface of the wire-gauze rests

has a shogging motion, or side-shake, which has an important effect in working the fibres together before the pulp finally settles down. When it reaches the *couching-rolls*, which press out most of the remaining moisture, and carry it forward to the first and second series of press-rolls by means of an endless web of felt which passes round them, the speed of these rollers and the travelling sheet of felt, CC (figs. 6 and 7), is nicely calculated, so as to prevent a strain upon the still very tender web of paper. Sometimes the upper rollers of these two series are filled with steam, in order to commence drying the web. The paper is now trusted to itself, and passes on, as indicated by the arrows, from the second press-rolls to the first set of *drying cylinders*, DD (figs. 6 and 7), where it again meets with a felt sheet, which keeps it in close contact with the drying cylinders, which are of large size, and filled with steam. Around these it passes, drying as it goes; is then received between the two *smoothing-rolls*, or damp calenders, which press both surfaces, and remove the marks of the wire and felt, which are until then visible on the paper. This is necessarily done before the drying is quite completed; and from the *smoothing-rolls* it passes to the second series of drying cylinders, E (figs. 6 and 7), where the drying is finished, and thence to the calenders, which are polished rollers of hard cast-iron, so adjusted as to give a considerable pressure to the paper, and at the same time a glossiness of surface. For writing-papers, the paper passes through a shallow trough of size after leaving the drying cylinders, and

Fig. 6.

Fig. 7.

then passes over another series of skeleton cylinders, with fans moving inside, by which it is again dried without heat, and afterwards passes through the calenders. Printing and other papers are usually sized by mixing the size in the pulp, in which stage the colouring materials—such as ultramarine for the blue tint of foolscap—are also introduced. Still following the paper web in the drawing (fig. 6), it is seen to pass from the calenders to another machine, F; this slits the web into widths, which are again cross cut into sheets, the size of which is regulated at will. The water-mark is impressed on machine-made paper by means of a fine light-wire cylinder with a wire-woven pattern; this is placed over the wire-gauze sheet upon which the pulp is spread, but near the other end of it, so that the light impression of the marker may act upon the paper just when it ceases to be pulp, and this remains all through its course. There are many other interesting points about the paper-machine, but their introduction here would rather tend to confuse the reader. Its productive power is very great; it moves at a rate of from 30 to 70 feet per minute, spreading pulp, couching, drying, and calendering as it goes, so that the stream of pulp flowing in at one end is in two minutes passing out finished paper at the other. It has been computed that an ordinary machine, making webs of paper 54 inches wide, will turn out four miles a day, and that the total production of all the mills in Britain is not less than 6,000,000 of yards, or 3400 miles daily.

For very obvious reasons, the manufacture of paper has been localised on the banks of streams that afford an abundant supply of pure water for washing and pulping. Kent is celebrated for its paper-mills and for the fine quality of its paper, and is the chief county in this respect. Next follow Hertfordshire (where it was first commenced in England in 1490 by John Tate of Stevenage, of whom it is said in a book printed by Caxton,

Which late hathe in England doo make thya paper thynne,
That now in our Englyssh thys booke is printed inne;

and the same John Tate is mentioned in Henry VII.'s Household Book, under dates May 25, 1493 and 1499, 'for a rewarde geven at the paper-mylne,' and 'geven in rewarde to Tate of the mylne, 6s. 8d.'). Buckinghamshire, Oxfordshire, and Lancashire. It was introduced into Scotland in the year 1695, when a company was formed for carrying it on under 'Articles' signed at a general meeting held in Edinburgh, which articles are now in the Library of the British Museum. It has become a very important branch of manufacture; and not only is paper of a very fine quality made from rags and the new material Esparto, Alfa, or Spanish Grass (the *Lygeum Sparteum* of botanists), but also the manufacture of paper-machines is carried on most successfully both for foreign and home use. Both of these manufactures are carried on in the immediate neighbourhood of Edinburgh. Since the introduction of the penny postage, penny papers, and other economical measures, especially the abolition of the excise-duty, an enormous impetus has been given to this branch of our home-manufacture, and considerable difficulty has been found in supplying the makers with raw material: this difficulty has been much increased by the export duties laid by other countries upon the export of rags. The greatest relief has been experienced by improved methods for preparing paper pulp from straw, and from the introduction of the Esparto, which yields half its weight of paper. Of this material our imports have risen to 190,000 tons per annum, which represents 95,000 tons of paper. The imports of

rag, notwithstanding the foreign impediments, are also very large. During the five years ending in 1875, they were as follows: 1871, 26,868 tons; 1872, 22,254 tons; 1873, 16,151 tons; 1874, 17,232 tons; 1875, 15,879 tons. In 1880, the 29,642 tons imported were valued at £451,782. Judging from good data, this manufacture has more than trebled since the abolition of the paper-duty, at which time it was very nearly 100,000 tons, a quantity so vast, that it will remove all surprise at the difficulty of supplying the raw materials.

The following are the principal varieties of ordinary paper, and the sizes of the sheets given in inches:

1. *Writing and Printing Papers*.—*Pot* (so named from its original water-mark, a tankard), 12½ by 15; *Double Pot*, 15 by 25. *Foolscap*, 16½ by 13½; *Sheet-and-third Do.*, 22½ by 13½; *Sheet-and-half Do.*, 22½ by 13½; *Double Do.*, 27 by 17. *Post* (so called from its use in letter-writing; one of its original water-marks was a postman's horn), 18½ by 15½; *Large Do.*, 20½ by 16½; *Medium Do.*, 18 by 22½; *Double Do.*, 30½ by 19. *Copy*, 20 by 16½. *Double Crown*, 20 by 30. *Demy*, 20 by 15; *Printing Do.*, 22½ by 17½; *Medium Do.*, 22 by 17½; *Medium Printing Do.*, 23 by 18½. *Royal*, 24 by 19; *Printing Do.*, 25 by 20; *Super-royal*, 27 by 19; *Super-royal Printing*, 21 by 27. *Imperial*, 30 by 22. *Atlas*, 34 by 26. *Columbier*, 34½ by 23½. *Elephant*, 28 by 23; *Double Do.*, 26½ by 40. *Antiquarian*, 53 by 31: this is generally, if not always, hand-made.

These sizes are somewhat lessened by ploughing and finishing off the edges previous to sale.

2. *Coarse Papers for wrapping and other purposes*.—*Kent-cap*, 21 by 18; *Bag-cap*, 19½ by 24; *Havon-cap*, 21 by 16; *Imperial-cap*, 22½ by 29. *Double 2-lb.*, 17 by 24; *Double 4-lb.*, 21 by 31; *Double 6-lb.*, 19 by 28. *Cartridge*, *Casing*, and *Middle-hand*, &c., 21 by 18. *Lumber-hand*, 19½ by 22½; *Royal-hand*, 20 by 25; *Double Small-hand*, 19 by 29.

Purple papers of a soft texture, unsized, are used in very large quantities by sugar-refiners, of the following sizes: *Copy-loaf*, 16½ by 21½; *Powder-loaf*, 18 by 26; *Double-loaf*, 16½ by 23; *Single-loaf*, 21½ by 27; *Lump*, 23 by 33; *Hambro'*, 16½ by 23; *Tiller*, 29 by 35; *Prussian*, or *Double Lump*, 32 by 42.

Blotting and Filing Paper.—This is unsized paper, made of good quality, and usually coloured pink or red, and of the same size as demy.

Besides these, which are well-known trade definitions, there are very many others, amounting, if we include *paste* and *mill boards*, to at least twelve or fifteen hundred, so that even paper-manufacturers require the aid of a treatise upon the subject of the sizes, qualities, &c., and such a treatise is in common use.

Even as regards materials, varieties are endless. In an old German book by Jacob Christian Schäffers, published at Regensburg in 1772, there are no less than eighty-one samples of different kinds of paper bound up and forming part of the book, and innumerable others have been made since.

Rice paper is a beautiful material imported from China, about which numberless errors have been written. It is now known to be formed of thin slices of the pith of the plant called *Aralia papyrifera*. This pith can be obtained from the stems in beautiful cylinders, from one to two inches in diameter, and several inches in length. The Chinese workmen apply the blade of a sharp, straight knife to these cylinders of pith, and, turning them round dexterously, pare them from the circumference to the centre, making a rolled layer of equal thickness throughout. This is unrolled, and

weights are placed upon it until it is rendered perfectly smooth and flat. Sometimes a number are joined together to increase the size of the sheets. It will be seen that this more nearly resembles the ancient papyrus than modern paper; but it is more beautiful than the former, being a very pure pearly white, and admirably adapted to the peculiar style of painting of the Chinese.

The ordinary papers of the Chinese, Japanese, and East Indians have much resemblance to each other, which arises from the manufacture and material being similar; the bark of the paper mulberry (*Broussonetia papyrifera*) being chiefly used. The Chinese and Japanese are the most skilful paper-makers in the world, and some of the East Indian papers surpass the European manufactures completely.

Some useful kinds of paper are the result of manipulations subsequent to the paper-maker's work. Thus:

Lithographic Paper is prepared from good printing-paper by laying on one side of the sheets a preparation consisting of six parts of starch, one of alum, and two of gum-arabic dissolved in warm water, and applied whilst hot with a proper brush. Generally a little gamboge is added, to give it a slight yellow colour.

Copying Paper, for manifold-writers, is made by applying a composition of lard and black-lead to one side or both of sheets of writing-paper; and after leaving it on for a day or so, it is carefully and smoothly scraped off and wiped with a soft cloth.

Tracing Paper is good printing-paper rendered transparent by brushing it over with a mixture of Canada balsam and oil of turpentine, or nut oil and turpentine. In either case it must be carefully dried before using.

There are two distinct classes of coloured papers. In one, the colour is introduced into the pulp, and is consequently in the body of the paper; in the other, the colours are mixed with size, and applied to the surface. There have been many ingenious and tasteful inventions for decorating the surface of paper, such as by giving it a marbled and even a beautiful iridescent appearance, but they are too numerous for the limits of this article.

Paper is subject to much adulteration. China-clay and gypsum are generally used for the white sorts, and the heavy ferruginous ochres for the coarse and brown kinds.

PAPER-BOOK, in English Law, is the name given to the pleadings on both sides in an action at law, when the issue is one, not of fact, but of law.

PAPER-HANGINGS. This name is applied to the webs of paper, *papiers peints* of the French, usually decorated, with which interior walls are often covered. Previous to the invention of the paper-machine, sheets of paper of the size called *Elephant*, 22 by 32 inches, were pasted together, to make 12 yard lengths, before the pattern was imprinted; but this is now rendered unnecessary by the facility of making webs of any length. Upon the paper it is usual first to spread a ground-colour, with proper brushes, taking care to produce a perfectly smooth surface. The colours employed are opaque, and are mixed with size, and sometimes also with starch, and most of the ordinary pigments are used. In the early stages of the art, it was usual to have the patterns stencilled (see **STENCILLING**) on the ground-colour. The stencilling plates were usually pieces of pasteboard, one being required for every differently-coloured portion of the pattern. Afterwards, wooden blocks were adopted, similar to those used in calico-printing, made of pear or poplar wood, generally the width of the paper,

forming, indeed, huge woodcuts, on which the pattern is in high relief. As many blocks are required as there are colours in the pattern, each bearing only so much of the pattern as is represented by the colour to which it is assigned. Of course, the whole beauty of the work depends upon the nice adjustment of one portion of the pattern to another; and this is determined by guide-pins in the blocks, which are so managed as not to disfigure the surface with their points. The pattern-block, being coated with its particular colour from the colour-tub, is laid on the paper, which is stretched out for the purpose on a table, and a lever is brought to bear upon it with sufficient pressure to make the whole of the block bear equally upon the paper. When one block has been printed the whole length of the paper by a succession of impressions, the piece is taken to the drying-room, and dried, previous to receiving the next colour; and it often happens that the same operations have to be repeated a dozen different times before the pattern is completed. This process is now being rapidly superseded by the cylinder printing-machines, which are of the same kind as are used in printing textile fabrics. In these machines, the pattern is engraved on a series of copper cylinders, and each part or colour has a separate cylinder, and an arrangement for keeping it constantly supplied with colour when working. The cylinders are so arranged as, by the sum of their revolutions, to make the pattern complete; so that as the web of paper passes the first, it receives the colour for one portion of the pattern, and reaches the second in exact time to have the next colour applied in the right places. In this way the entire piece only occupies a few seconds in receiving the complete decoration.

The polished or glazed papers have the ground prepared with gypsum or plaster of Paris, and the surface dusted with finely-powdered steatite, or French chalk. When perfectly dry, this is rubbed hard with a burnishing-brush, until the whole is evenly polished. This is generally done before the pattern is printed, but in some cases pattern and ground are both polished. In making the *flock-papers*, the printing is done in the same way as in the block-printing, only, instead of coloured material, a composition called *encaustic* is printed on. It consists of linseed-oil, boiled with litharge, and ground up with white-lead; sufficient litharge is used to make it dry quickly, as it is very adhesive. The flock is prepared from the shearings of woollen cloths from the cloth-mills, by washing and dyeing the shearings to the various colours, then stove-drying and grinding them in a peculiar mill, which, in their brittle state, after leaving the stove, breaks them short. After this they are sifted, to obtain various degrees of fineness. By nice management, the prepared flock is so sprinkled over the whole of the printed surface as to coat the encaustic, and adhere evenly and firmly to it. The same adhesive material is used for printing in gold and other metals. The pattern being printed with the encaustic, gold or other metallic leaf is applied, and when it is properly fixed, the loose metal is brushed away with a hare's-foot or other soft brush. Some of the finest French papers have much of the pattern actually painted in by hand, a process which, of course, renders them very costly.

PAPER MULBERRY. See MULBERRY.

PAPER NAUTILUS. See ARGONAUT.

PAPHLAGONIA, anciently a province of Asia Minor, extending along the southern shores of the Black Sea, from the Halys on the east, to the Parthenius on the west (which separates it from Bithynia),

and inland on the south to Galatia. Its limits, however, were somewhat different at different times. The Paphlagonian mountains were covered with forests, and the inhabitants were famous as hunters. Croesus made P. a part of the kingdom of Lydia, and Cyrus united it to Persia; it subsequently became part of the empire of Alexander the Great, and afterwards of the kingdom of Pontus, was included in the Roman province of Galatia, and in the 4th c. of the Christian era was made a separate province by Constantine. Its capital was Sinope. The Paphlagonians are supposed to have been of Syrian, or at least of Semitic origin, like the Cappadocians. They were proverbially rude, coarse, and deficient in understanding, but this probably refers only to the country-people in the interior.

PAPHOS, anciently the name of two cities in the isle of Cyprus. The older city, sometimes called *Palapaphos* (now *Kuklos* or *Konuklia*), was situated in the western part of the island, about 1½ miles from the coast. It was probably founded by the Phœnicians, and was famous, even before Homer's time, for a temple of Venus, who was said to have here risen from the sea close by, whence her epithet *Aphrodite*, 'foam-sprung,' and who was designated the Paphian goddess. This was her chief residence, and hither crowds of pilgrims used to come in ancient times.—The other Paphos, called *Neopaphos* (now *Baffa*), was on the sea-coast, about seven or eight miles north-west of the older city, and was the place in which the apostle Paul proclaimed the gospel before the proconsul Sergius.

PAPIAS, Bishop of Hierapolis in Phrygia, was a Christian writer, who flourished in the 2d century. According to Irenæus, he was a disciple of the apostle John; but Eusebius, who quotes (*Historia Ecclesiastica*, chap. 39) the words of Irenæus, immediately subjoins a passage from P. himself, in which the latter distinctly states that he did not receive his doctrines from any of the apostles, but from the 'living voice' of such followers of theirs as 'are still surviving.' He was, however, an 'associate' of Polycarp, a bishop in the same province of proconsular Asia; and as the latter was a disciple of the apostle John, it is probable that Irenæus—a somewhat hasty writer—inferred that his companion must have been the same. The *Paschal or Alexandrian Chronicle* states that he suffered martyrdom at Pergamus, 163 A.D. Eusebius describes P. as 'well skilled in all manner of learning, and well acquainted with the Scriptures;' but a little further on, he speaks of him as a man 'of limited understanding' (*smilerte en tèn nodn*), and a very credulous chronicler of 'unwritten tradition,' who had collected 'certain strange parables of our Lord and of his doctrine, and some other matters rather too fabulous.' The work in which these were contained was entitled *Logion Kurikên, Ewangelis Biblia B'*. (Five Books of Commentaries on the Sayings of our Lord). It is now lost, but certain fragments of it have been preserved by Irenæus, Eusebius, Maximus Confessor, and other writers. These fragments are extremely interesting, because of the light which they throw on the origin of the New Testament Scriptures, and their importance may be estimated from the fact, that they contain the earliest information which we possess on the subject. It is P. who is our authority for the statement, that the evangelist Matthew drew up a collection of our Lord's sayings and doings (*ta logia*) in the Hebrew (probably Syro-Chaldaic or Aramaic) dialect, and that every one translated it as he was able. There can be no doubt that this is a perplexing statement, suggesting as it does the delicate question: 'If Papias is correct, who wrote our present Matthew, which is in Greek,

and not in Hebrew?' (For a consideration of this point, see MATTHEW.) P. also tells us, either on the authority of John the Presbyter, or more probably on that of one of his followers, that the evangelist Mark was the interpreter (Hermeneutes) of Peter, and wrote 'whatsoever he [Peter] recorded, with great accuracy.' But the passage is far from implying that Mark was a mere amanuensis of Peter, as some have asserted, but only, as Valesius has shewn, that Mark listened attentively to Peter's preaching, culled from it such things as most strictly concerned Christ, and so drew up his gospel. P., it remains to be said, was an extreme millenarian. See MILLENNIUM.

PAPIER-MÂCHÉ (Fr. mashed or pulped paper). This manufacture has certainly been in use for more than a century in Europe; but it is not improbable that it was first suggested by some of the beautiful productions of Sindé and other parts of India, where it is employed in making boxes, trays, &c., as well as in China and Japan. Its first application, as far as we know, was to the manufacture of snuff-boxes by a German named Martin, in 1740, who learned it of a Frenchman named Lefevre; but the French say that he learned the art in England. Properly speaking, papier-mâché is paper-pulp moulded into shape, and it has been used, not only to make small articles, such as boxes, trays, &c., but in the interior decoration of houses for cornices, ceilings, &c. The ceilings in Chesterfield House, and some other fine Elizabethan structures, are made of this material, which at one time, owing to a combination of the stucco-workers to raise the price of their labour, took the place almost entirely of stucco in house ornamentation. At present, a combination of both stucco and paper is similarly employed under the name of *Carton-pierre*. From the extension of the applications of papier-mâché to the manufacture of a number of light and useful articles, modifications have taken place in its composition, and it is now of three kinds—1st, the true kind, made of paper-pulp; 2d, sheets of paper pasted together after the manner of pasteboard, but submitted to far greater pressure; and 3d, sheets of thick millboard cast from the pulp are also heavily pressed. The term papier-mâché is in trade held to apply rather to the articles made of the pulp than to the pulp itself; and a vast manufacture has sprung up during the present century, particularly in Birmingham, in which a great variety of articles of use and ornament are made of this material. They are coated with successive layers of asphalt varnish, which is acted upon by heat in ovens until its volatile parts are dissipated, and it becomes hard, and capable of receiving a high polish. Mother-of-pearl is much used in their decoration, for which purpose, when several layers of the varnish still remain to be applied, thin flakes of the shell of the form of the pattern are placed on the varnish, and are covered by the succeeding layers, giving rise to elevations where they are hidden by the coats of varnish. The surface is then ground down smooth and polished, and the grinding down brings to light the pieces of mother-of-pearl shell, which thus present the appearance of inlaid patterns. The fine surface which can be given to the asphalt varnish, also permits of burnished gilding and other decorative applications with excellent effect.

PAPILIO. See BUTTERFLY.

PAPILIONACEÆ, a suborder of the natural order of plants generally called *Leguminosæ* (q. v.).—The plants of this suborder are the only plants known which have flowers of the peculiar structure called *papilionaceous*, and of which the Pea and

Bean afford familiar examples. The name is derived from Lat. *papilio*, a butterfly. Papilionaceous flowers have five petals, imbricated in estivation (bud), one of which, called the *vexillum*, or *standard*, is superior, turned next to the axis, and in estivation folded over the rest; two, called the *alæ*, or *wings*, are lateral; and two are inferior, which are often united by their lower margins, forming the *carina*, or *keel*. The number of the P. is very great—about 4800 species being known. They are found in all parts of the world, abounding in the tropics. Many have superb and beautiful flowers; many are plants of beautiful form and foliage, trees, shrubs, or herbaceous plants; many possess valuable medicinal properties; and many are of great importance as furnishing food for man and for domestic animals, others as furnishing dyes, fibre, timber, &c. See BROOM, LABURNUM, CLOVER, BEAN, PEA, LUCERNE, LIQUORICE, INDIGO, SANDAL-WOOD, &c.

PAPILLÆ. This term is applied by anatomists to minute, elongated, conical processes, projecting from the surface of the true skin into the epidermis, highly vascular and nervous in their character, and taking an active part in the sense of touch. Their form and structure are described in the article SKIN. The mucous membrane of the tongue also contains three varieties of papillæ, which are described in the article TASTE, ORGAN AND SENSE OF.

PAPIN, DENIS, a celebrated French physicist, was born at Blois, 22d August 1647, and studied medicine in Paris, where, after receiving his degree, he practised for some time as a physician. He now became acquainted with Huyghens—an incident which strengthened in him an original predilection for physical science; and from this time, he devoted himself almost exclusively to his favourite study. Before P.'s time, the intense force which can be generated in water, air, &c., under the action of heat, was well known, but he was one of the first to indicate the principal features of a machine by which this property could be made of practical utility. He soon acquired a wide reputation; and on visiting England, was received with open arms by the philosophers of that country, and became a member of the Royal Society in 1681. While in England, P. and Boyle (q. v.) together repeated their experiments on the properties of air, &c.; but in 1687, P. was called to the chair of Mathematics in the university of Marburg in Hesse-Cassel. In 1696 he went to live in the town of Cassel; and in 1707 he came to London. He died in poverty and neglect in 1712. The French Academy of Sciences, withholding from P. the honour of 'associate,' enrolled him among its 'correspondents'—a proceeding on the part of the Academy which has, with reason, excited the astonishment of F. Arago. To P. undoubtedly belongs the high honour of having first applied steam to produce motion by raising a piston; he combined with this the simplest means of producing a vacuum beneath the raised piston—viz., by condensation of aqueous vapour; he is also the inventor of the 'safety-valve,' an essential part of his 'Digester' (q. v.). By this latter machine, P. shewed that liquids in a vacuum can be put in a state of ebullition at a much lower temperature than when freely exposed to the air. P.'s sagacity led him to many other discoveries; he discovered the principle of action of the siphon, improved the pneumatic machine of Otto de Guericke (q. v.), and took part against Leibnitz in the discussion concerning 'living' and 'dead' forces. Unfortunately for science, P.'s numerous writings have not yet been collected, but many of them will be found in the *Philosophical Transactions*, *Acta Eruditorum*, and the *Recueil de Diverses Pièces*. He

published two works—one being an explanation of the construction and uses of his 'digester' (Lond. 1681), afterwards (1682) translated into French, and his experiments entitled *Nouvelles Expériences du Vide* (Paris, 1674). It was not till nearly a century after that the great value of P.'s discoveries was perceived. See his Life by Gerland (Berlin, 1881).

PAPINIANUS, **ÆMILIUS PAULLUS**, the most celebrated of Roman jurists, was born towards the middle of the 2d c.; and during the reign of the Emperor Severus (q. v.), whom he succeeded as *Advocatus Fisci*, and whose second wife is said to have been P.'s relative, he held the office of *Libellorum Magister*, and afterwards that of *Præfectus Prætorio*. After the death of Severus, his son and successor, Caracalla, dismissed P. from his office, and soon afterwards caused him to be put to death on various pretexts, the real reason, however, appearing to be that the emperor was afraid the influence of a man so able and upright would be dangerous to his power. P.'s works consist chiefly of 37 books of *Questiones*, 19 of *Responsa*, 2 of *Definitiones*, two works, *De Adulteriis*, and a Greek fragment; and from these works there are in all 595 excerpts in the Digest (q. v.). The pupils of P. include the most famous names in Roman jurisprudence, such as Ulpian, Paullus, Pomponius, Africanus, Florentinus, and Modestinus, but the master stands superior to them all. The high reputation he enjoyed among his contemporaries and successors may be gathered from the epithets *Prudentissimus*, *Consultissimus*, *Disertissimus*, bestowed upon him by various emperors, and from the first book of the Codex Theodosii, *De Responsis Prudentum*, in which, after declaring the works of P., Paullus, Caius, Ulpian, Modestinus, and four others, to be authority for a judge's decision, it is declared that should these jurists be equally divided in opinion, that opinion which was maintained by P. was to be considered right; while his commentator, the celebrated Cujacius (q. v.), goes so far as to declare 'that Papinianus was the first of all lawyers who have been, or are to be,' and that 'no one ever will equal him.' His high reputation as a jurist was much enhanced by the strong moral feeling and stern unbending honesty which were equally characteristic of him, and which have stamped his works with an ineffaceable impress. P.'s works were studied both before and after Justinian's time by Roman legal students of the third year, who were for this reason denominated Papinianists. The fragments of P.'s works which now remain are somewhat obscure, and the excerpts from them in the Digest are in general so brief, that the aid of a commentator is required.

PAPIST (Lat. *papista*, an adherent of the pope) is a name applied, generally with some admixture of contempt, to members of the Roman Church. Of itself, it implies nothing more than that they are adherents of the pope; but in its popular use it includes all the distinctive doctrines of Roman Catholics, and especially those which are supposed to be peculiarly cherished by the supporters of the papal authority. It is therefore in many cases held to be synonymous with the profession of the extremest opinions permitted in the Church of Rome, and even those which are popularly regarded as superstitious. Understood literally, no consistent Roman Catholic would disclaim it; but in the imputed signification explained above, it is held to be offensive.

PAPPENHEIM, **GOTTFRIED HEINRICH**, COUNT VON, an imperial general of great note in the Thirty Years' War, was born at Pappenheim, in Middle Franconia, Bavaria, 29th May 1594, of a very ancient Swabian family, in which the dignity

of Marshal of the Empire became hereditary about the 13th or 14th c., and many of whose members had greatly distinguished themselves in the wars of the middle ages. When about 20 years of age, P. went over to the Roman Catholic Church, and thenceforth signalled himself by his fiery zeal in its cause. After serving under the king of Poland in his wars with the Russians and Turks, P. joined the army of the Catholic League, and in the battle of Prague (1620) stayed the flight of the Austrian cavalry, and by a well-timed and furious charge turned the tide of battle against the Bohemians. In 1623, he received from the emperor the command of a cavalry regiment of the famous 'Pappenheimer Dragoons'; and in 1625, became general of the Spanish horse in Lombardy; but in 1626 re-entered the Austrian service, and after suppressing a dangerous revolt of the peasants of Upper Austria, in which 40,000 of the peasants perished, he joined the army which was opposed to the Protestant league, and, in association with Tilly, carried on many campaigns against the Danes, Swedes, and Saxons. It was P. who urged and induced Tilly to take Magdeburg by assault, and himself led and directed the attack. Moreover, it is he, rather than Tilly, who was to blame for the ferocious massacres which followed. His reckless bravery involved Tilly, against his will, in the disastrous battle of Breitenfeld; but to some extent he retrieved his character by his strenuous efforts to remedy the loss, and protect the retreat of the army. After Tilly's death, he was associated with Wallenstein, who detached him with eight regiments to protect Cologne, but on hearing of the advance of Gustavus, sent an urgent order for his return. P. arrived at Lützen at the moment when Wallenstein's army was on the point of being completely routed, and at the head of his cuirassiers, charged the left wing of the Swedes, throwing it into confusion, and almost changing the fortune of the battle by his extraordinary bravery. He was mortally wounded in the last charge, and died a few hours afterwards at Leipzig, November 7, 1632, with a smile on his countenance, after learning that Gustavus Adolphus had died before him. 'God be praised!' he said; 'I can go in peace, now that that mortal enemy of the Catholic faith has had to die before me.'

PAPPUS, in Botany, an appendage of the fruit of plants belonging to certain natural orders, of which the great natural order *Compositæ* is the chief.

It consists either of simple (figs. 1 and 4) or feathery (figs. 2 and 5) hairs, sessile or stalked, arising from the summit of the fruit, and is produced by a development of the tube and limb of the persistent calyx. Its object appears to be to waft the ripened seed to the new situation in which it is to grow. *Thistle-down* is the pappus of the thistle. — The pappus is sometimes represented by mere teeth or scales.

PAPPUS of Alexandria, one of the later Greek geometers, of whose history nothing is known; he is said by Suidas to have lived during the reign of Theodosius the Great, emperor of the East (379–395). Some writers are of opinion that he lived two centuries earlier, but the former is much the more probable opinion. The chief work of P.

Pappus:
1 and 2, sessile; 3, scale-like;
4 and 5, stalked.

is his *Mathematical Collections*, of which the last six, out of eight books, are extant. The *Collections*, as their name implies, are an assemblage into one book of scattered problems and theorems, the work of Apollonius, Archimedes, Euclid, Theodosius, &c., to which he has joined his own discoveries. The first two books are supposed (on insufficient grounds) to have treated of arithmetic and arithmetical problems, but only a small fragment of the second book is extant: the third book is a collection of problems, mostly of solid geometry: the fourth treats of curves other than the circle, according to the method of pure geometry: the fifth contains problems of maxima and minima: the sixth treats of the geometry of the sphere: the seventh, which is by far the most important to modern geometers, as it is almost the sole authority we possess on the subject of the history and methods of the Greek geometrical analysis, treats principally of analysis; it also contains the proposition now known as 'Guldinus' Theorem,' which was plagiarised from P. by Father Guldin: the eighth and last book treats of machines. P. was the author of several other works which are lost, excepting only a fragment of his *Commentary on Four Books of Ptolemy's Syntaxis*. P., as an independent investigator, enjoys a high reputation, and is considered by Des Cartes as one of the most excellent geometers of antiquity. Some of his problems have been looked upon with high interest by all succeeding geometers. The first complete editions of the *Collections* of P. were those of Commandine (Pesaro, 1588) and Manolissius (Bologna, 1660). The best edition is that published at Berlin in 1876-78, by Friedrich Hultsch, *Pappi Alexandrini Collectionis quæ supersunt*.

PAPUA, or NEW GUINEA, is, with the exception of Australia, the largest island on the globe. It lies in lat. $0^{\circ} 30'$ — $10^{\circ} 40'$ S., and long. 131° — $150^{\circ} 30'$ E., and is about 1500 miles in length from north-west to south-east, with a varying breadth of from 200 to 400 miles, and an area estimated at 250,000 square miles. (The name *Papia* means 'frizzly haired.') In outline the island is very irregular, the western part being nearly insulated by Geelvink Bay on the north, and McClure's Inlet from the west. The head of Geelvink Bay is separated from the south coast by an isthmus only 35 miles in breadth. Eastward from this, the island increases to its greatest breadth, and terminates in the south-east, in a narrow peninsula of lofty mountains. East of Torres Strait is a deep bay, called the Great Bight of New Guinea, its eastern shore being bold and rocky, with extensive coral reefs; its western, flat and marshy, covered with dense forests, and intersected with countless fresh-water canals. The Fly, the largest river of the island, empties into it. The nearest point to Australia is about 90 miles distant.

The island seems to have been first sighted by Portuguese navigators in 1526 and in 1528. In 1545, a Spanish captain sailed 250 miles along its northern coast, and gave it the name of New Guinea, from a fancied resemblance it bore to the Guinea coast of Africa. In 1606, a Spanish frigate under Captain de Torres, sailed along the southern shore to the strait that bears his name. In 1676, the Dutch captains, Schouten and Le Maire, landed on the island to obtain fresh water, and were attacked by the natives. M. De Bougainville, in 1768, also made the south coast of the island, and worked to windward along it. The English navigators, Cook in 1770, and Forrest in 1774, Edwards in 1791, and the following year Captain Bligh, of *Bounty* notoriety, saw portions of the south coast. Flinders, in 1799, visited the island, and added a few facts to our scanty information. In the course of

the voyage of the French ship *Astrolabe*, under the command of J. Dumont d'Urville, the distinguished naturalists, Quoi and Gaymard, studied the natural history of the island, and more especially its zoology. A Dutch expedition in 1828 added to the information of the western coast. In 1845, Captains Blackwood and Owen Stanley, of Her Majesty's ships *Fly* and *Bramble*, surveyed part of the southern coast; and between 1846 and 1850, the last-named officer surveyed the southern shores of the eastern peninsula. In 1853, the Dutch government sent a surveying expedition in the steamer *Etna* to the north and north-west coasts. In 1869, attention was called to our lack of information on P., and to the fact that so little had been done to explore this great and fertile island, which lay almost within sight of Australia, and might be looked on as belonging to that continent. Sir Charles Nicholson especially directed the attention of our Australian colonists to the importance of their becoming acquainted with the island, lying, as it does, on the highway to India and China, and believed to be rich in minerals and commercial products. In 1871, a Russian steam corvette left on the north-east shores the naturalist, Miklukho Maclay, who lived for 15 months there, and has repeatedly visited P. since. Meyer, and the Italian travellers Beccari and D'Albertis, have added much to our knowledge of the interior. The agents of the London Missionary Society have also extended our knowledge of the country. Early in 1873, H.M.S. *Basilisk*, Captain Moresby, was sent to suppress the system of kidnapping natives in the neighbourhood of Torres Strait; and this being accomplished, Captain Moresby employed his time in continuing the survey of the eastern coasts commenced by Captain Owen Stanley. He found the eastern part of the island different in form from the representations as given on our maps, inasmuch as a considerable portion of the eastern promontory consisted of islands with deep channels between, instead of being a continuous line of coast. But little is known of the geography of the island beyond the coast. The northern side is hilly and densely covered with wood, whilst such portions of the southern coasts as have been visited are low, and apparently swampy, but still densely wooded. A range of mountains, the Charles Louis Mountains, commences on the south coast near Geelvink Bay, and extends due east, rising gradually to a height of nearly 17,000 feet, where it is lost sight of at a distance of 100 miles from the coast; but it is not improbable that this range continues through, and subdivides the island until it joins the high land of the eastern peninsula, where a succession of mountains, from 14,000 to 5000 feet high, continue to the eastern extreme. A large island, Frederick Henry Island, 100 miles long by about 60 broad, on the south-west coast, was supposed to be part of the mainland until a Dutch officer passed through the strait that separated it. The northern coast from East Cape to the boundary of the Dutch territory, a distance of nearly 1000 miles, was surveyed by Dr Finckh, in the steamer *Samoa*, in 1884. Numerous expeditions have been despatched in recent years by the Australian colonies or by England, but perhaps the explorations of Mr Chalmers and Mr Forbes have contributed the most to our knowledge of the island. Two Melbourne newspapers have taken an honourable part in the work, and a scientific expedition was despatched by the Geographical Society of Australasia in 1886. The whole of the south-eastern coast to the eastern extreme of the island, and on to the Louisiade Archipelago beyond, is fringed with dangerous coral reefs. China Strait, at the south-east point of the main island, is, however, navigable for large ships.

The tides, however, at springs, run at the rate of 5 or 6 knots, but more careful and elaborate surveys will doubtless render navigation more safe and expeditions in these waters.

There cannot be a doubt that in an island of such vast extent as P., not only does the character of the human family greatly diverge, but there may possibly exist several distinct races. With our little knowledge, two distinct races are admitted, viz., the Papuans, so called from the Malayan 'frizzled hair,' and the Haraforas. The Papuans are said to resemble the Australian aborigines, but, as a rule, are stouter. The Haraforas are distinguishable from the Papuans by lighter colour and straighter hair; they also exhibit greater activity of body.

Except in the swampy districts, the climate is not unhealthy, though the temperature varies greatly, the thermometer sometimes indicating 95° F. by day, and falling to 75° by night. On the south-west coast, the east monsoon or rainy season begins about the middle of April, and ends in September; the dry season is from September to April, and on the north coast they are just reversed.

The island is everywhere clothed with the most luxuriant vegetation, cocoa-nut, betel, sago, banana, bread-fruit, orange, lemon, and other fruit-trees lining the shores; while in the interior are abundance of fine timber trees, as the iron-wood, ebony, canary-wood, the wild nutmeg, and the massoi, the fragrant bark of which is a leading article of export from the south-west coast. In the districts of the Arfak and Amberbakin Mountains the sugar-cane, tobacco, and rice are cultivated.

The natural history of the western part of P. has been recently examined by Mr Wallace. This naturalist established the fact that a deep channel in the bed of the ocean, running west of Celebes, and east of the great islands of Java and Borneo, now known as Wallace's Line, separates two regions, in which the islands rise from shallow waters, and which are totally unlike each other in their botany and zoology. The islands on either side of this line he supposes to be the relics of submerged continents. Those on the west, or the Great Malay Islands, belong to the continent of Asia, and have its plants and animals. Those to the east of the line, on the other hand, including P., have a flora and fauna resembling those of Australia. The latter island has a dry climate and stunted vegetation. P., on the contrary, has a warm and moist climate, pre-eminently fitted to produce a varied, luxuriant vegetation; and it is clothed from end to end with magnificent forests. Insect life is, as might be expected, abundant and varied; the Papuan species being remarkable for fine forms and beautiful colours. Still more interesting to the naturalist is the variety of birds, of which 120 species are singers, 30 parrots, and 28 pigeons. Those of land species which have been examined belong to 108 genera, 29 of which are found exclusively in Papua. The beautiful birds of paradise are peculiar to the island, and distinguish it from all other regions. In contrast to this variety of birds is the small number of mammals. The great pachyderms and quadrumana of the Malay Islands are wanting, and the mammals are 2 bats, 1 pig, 10 marsupials, 1 cetacea, and 1 carnivora. There is one true kangaroo similar to those of Australia. The climbing kangaroos take the place of the monkeys of the Asiatic area. It is believed that Wallace's Line, or one nearly coincident with it, separates two varieties of the human race, the Malays and the Papuans, or rather areas in which one of these races predominates.

Mr Alfred Wallace, in his *Malay Archipelago*, says of the Papuans: 'There has been much difference of opinion about the races of the Oceanic region,

but it is generally admitted that they belong to four different types—those of (1) the Malays; (2) the Negritos or Papuans; (3) the Polynesians; (4) the Australians. The most distinguished of recent ethnologists class the Malays with the Mongols; the Negritos or Papuans, and the Polynesians, with the negroes of Africa; and distinguish widely the Australians from both. They do not recognise any fundamental distinction between the dark Papuans and the light-complexioned Polynesians. The western parts of the island are inhabited by the former, the eastern parts by the latter. The Papuans are well made, have regular features, intelligent black eyes, small white teeth, curly hair, thick lips, and large mouth; the nose is sharp, but flat beneath, the nostrils large, and the skin dark brown. They are,' Mr Wallace says, 'superior in stature to average Europeans, but have long and thin legs, and the splay foot of the negro.' He thinks the Papuans superior to the Malays in intelligence. In the western parts, they are divided into small distinct tribes, frequently at war with each other. The men build the houses, hollow the trunks of trees into canoes, hunt and fish; while the women do all the heaviest work, cultivating the fields, making mats, pots, and cutting wood. Their food consists of maize, sago, rice, fish, birds, the flesh of wild pigs, and fruits, &c. 'They are copper coloured, of a light active build, often with very good features, which they paint; but the men's teeth and mouths are much disfigured by constant use of betel-nut. The hair is usually worn frizzled out into a huge mop. The women's hair is always cut short. Their weapons appear to be spears, swords, clubs, and stone hatchets, but no bows and arrows were seen amongst them. Occasionally human jaw and spinal bones are worn as bracelets and ornaments. They appeared to take pleasure in making us understand that they had eaten the original owners of the bones; but these bones, as well as the few skulls exhibited in their villages, appeared to be of an ancient date. The houses are built after the Malay fashion, on poles raised 5 or 6 feet above the ground, and consist of one large apartment.' The natives of Humboldt's Bay have a temple in every village, though nothing is known of their religion.

In the eastern part of the island, the negro type of the inhabitants passes into that of the Polynesians. Captain Moresby says of them, that they have the light complexion and in all respects the appearance of the Polynesians, typically represented by the New Zealanders, that they are a friendly and intelligent people, and gladly received the English seamen at their villages, where they mixed freely with them. They practise several useful arts, such as pottery, and possess extensive, well-fenced plantations. In the north-eastern part of the island, their villages are terraced and cultivated to a great height, in a manner which a Chinaman might envy. Captain Moresby believes them to be a fine, promising race, and thinks that, with the aid of civilising influences, a prosperous future is in store for them.

The Dutch scientific expedition of 1858 appended to their report a vocabulary of the Myfore language, of about 1200 words, collected by Ottow and Geisler, missionaries at Doreh, on the west of Geelvink Bay. It is, however, known to differ greatly from languages spoken in other parts; and natives of the South Sea Islands have a facility in communicating with the Papuans on the Torres Strait. The London Missionary Society has therefore begun to Christianise them through Samoan teachers directed by British missionaries. The first chapel, on Murray Island, was opened in 1875.

The population of P. and the immediately

adjacent islands has been very variously estimated. Mr Chalmers believes that it cannot be more than 2,500,000. The exports are massoi bark, trepang or béche-de-mer, tortoise-shell, pearls, nutmegs, birds of paradise, crown-pigeons, ebony, resin, &c.

The inhabitants seem to be divided into a great number of petty tribes, quite independent of each other. No native government is known to extend over a great part of the island. The Dutch acquired the rights of their tributary, the sultan of Tidore, and it was partly to assert them that an expedition was undertaken in 1828. At this time, the Dutch built a fort called Du Bus, in Triton Bay, 3° 46' S. lat., and 134° E. long., and declared the whole island west of a line running from Cape Bonpland in the north, along 141° E. long., to Torres Strait, to belong to the Netherlands, but the settlement was abandoned. In 1858, the Dutch made another attempt to establish a colony. The *Etna* was fitted out for that purpose. The expedition visited a great part of the north-western coast. Recent attempts of parties of miners to tap the metallic treasures of P. have not as yet met with success.

That a great future is open to this vast territory is undoubted. Rich in natural products and mineral wealth to an extent of which we can have no conception, situated in such close contiguity to one of our largest possessions, and between it and China, Japan, and India, it is of immediate consequence to England; the western part may be regarded as under the Dutch power. In 1883, the government of Queensland annexed the eastern portion of P., but its action was not sanctioned by the imperial government, and it was not till the close of 1884 that the area of this protectorate was defined. Immediately afterwards, the Australian colonies were startled by the news that the German flag had been hoisted at several places along the north-east coast and on many of the adjacent islands. The boundaries since agreed upon give an area on the German side of about 67,000 sq. miles; on the English, of 63,000 sq. miles; and nearly approaches the water-parting line or natural boundary.

PAPULÆ AND PAPULAR DISEASES.

Papulae, or pimples, constitute one of the eight orders of Bateman and Willan's classification of cutaneous diseases. They occur as little elevations of the cuticle, of a red colour, containing neither pus nor any other fluid, and ending usually in a scurf. They are generally supposed to denote inflammation of the papillæ of the skin; but Erasmus Wilson believes that they represent an inflammatory condition of the secretory orifices, whether sudoriferous or sebaceous. The diseases regarded as papular are Strophulus, Lichen, and Prurigo; but there are other diseases in which the first external symptom is a papular eruption, as, for example, small-pox, in which the papula speedily develops itself into a pustule.

PAPYRI. Rolls made of the paper of the papyrus plant are commonly known as *papyri*, corresponding to the Greek *biblia*. These rolls are of a very remote antiquity, some of the still remaining Egyptian papyri being certainly as old as the 6th dynasty, and others as old as the 12th, or from about 2000 B.C. This is owing to their mode of preservation, and to the peculiarly dry character of Egypt. These rolls have been found deposited in different ways, those of a religious nature being placed upon the bodies of mummies, at the feet, arms, or even in the hands, sometimes, indeed,

packed or laid between the bandages, or even spread over the whole bandages, like a shroud. At the time of the 19th and 20th dynasties (1320—1200 B.C.), they were often deposited in hollow wooden figures of the god Ptah Socharis Osiris, or of the god Osiris, which were placed near the mummies. Papyri of a civil nature were deposited in jars or boxes, which were placed near the mummies, or have been found in the remains of ancient libraries. The following are the principal kinds of Egyptian papyri: 1. Hieroglyphical papyri, always accompanied by pictures or vignettes, and consisting of three classes: 1. Solar litanies or texts, and pictures relating to and describing the sun's passage through the hours of the night, when that luminary was supposed to enter the Egyptian Hades or Hell. 2. Books of the empyreal gate, or heaven, with vignettes of deities, and other representations referring to the genesis of the cosmos or universe. 3. The so-called Ritual, consisting of a series of sacred or hermetic books, some of a very remote antiquity, accompanied with rubrical titles and directions as to their efficacy and employment, and comprising various formulas ordered to be placed on the coffins, amulets, and other furniture of the dead, for the better preservation of the souls of the dead and of the mummies in the future state. In this book, chapters giving an account of the future judgment, of the *makheui*, or boat of the dead, of the Elysian Fields, and of the Halls through which the dead had to pass, are also found. The work was considered by the Egyptians themselves mystic, and parts were supposed to be written by the god Thoth himself. A copy more or less complete, according to the wealth of the deceased, was deposited with all the principal mummies; and from the blank spaces left for the name, which were afterwards filled up, it is evident they were kept ready made.

—II. Hieratic papyri, written in the hieratic or cursive Egyptian hand, comprising a more extensive literature than the hieroglyphic papyri. This handwriting being used for civil as well as religious purposes, the papyri found in it differ considerably from one another, and comprise rituals of the class already mentioned, principally in use about the 26th dynasty, or the 6th c. B.C., but found also on some few papyri of a remote period; a book called the *Lamentations of Isis*; magical papyri, containing directions for the preparation of charms and amulets, and the adjuration of deities for their protection; civil documents, consisting of the examination of persons charged with criminal offences, the most remarkable of which are that of an offender charged with the practice of magic in the 19th dynasty, another of a criminal charged with various crimes, in the reign of Sethos I., the examination of a conspiracy in the palace of Rameses II., and the *procès-verbal* of an offender charged with violating the sepulchres of the kings in the reign of Rameses IX. Besides these, there are several letters of various scribes upon subjects connected with the administration of the country and private affairs; laudatory poems of Egyptian monarchs, one describing the campaign of Rameses II. against the Khita or Hittites; historical documents, the journeys in foreign parts; the endowment of temples by Rameses III.; works of fiction, one of the adventures of two brothers, the death of the younger, owing to the false accusation of the wife of the elder, his revival, and transformation into a bull and a Persea tree; another, the story of a doomed prince, and the adventures of different persons. Works on plants and medical subjects, books of proverbs, lists of kings, historical accounts, are amongst these documents.—III. The last class of Egyptian papyri, those written in the demotic or enchorial

character, consist of rituals, contracts for the sale of mummies and lands, accounts and letters, and miscellaneous documents. These papyri are often bilingual, sometimes accompanied with hieratic or Greek versions. Many of these papyri have been translated by De Rougé, Chabas, Heath, Goodwin, Birch, and others. Many Greek papyri have been found belonging to the archives of the Serapeion, referring to the administration of that temple, the orations of Hypereides, and some of the books of Homer. At all times in the history of Egypt, libraries of papyri seem to have existed, and, under the Ptolemies, are said to have contained as many as 700,000 rolls.

Another class of ancient papyri, those of Pompeii and Herculaneum, are of considerable interest, as shewing the condition and arrangement of a Roman library. The papyri of Herculaneum are from $8\frac{1}{4}$ to $12\frac{1}{2}$ inches wide, and are rolled up in a cylindrical roll, *volumen*, upon a stick or inner roll, *bacillus*, *umbilicus*, having a stud at the end, *cornu*. They had their titles written on a strip, *lorum*, in red letters, and the writing was either on blind lines, or else on lines ruled with lead. About 1800 papyri were discovered at Herculaneum, in 1753, in the library of a small house, charred to a cinder, and some of these, by the greatest skill and care, have been unrolled by a very laborious process at Naples. Unfortunately, they have not answered the literary expectations formed of them, consisting of the works of philosophers of the Epicurean school, which the proprietor of the library seems to have collected. Some of the papyri were in Latin, and more difficult to unroll. Many of them have been published. They are only written on one side. When a small number were required, they were placed in a cylindrical bronze chest (*cista*), packed tightly in a perpendicular position, and were taken out single, and read by unrolling from one end. These papyri were of various prices; old ones, like old books, being of immense value, but those containing the works of contemporary authors were not dearer, perhaps, than modern books. Many extensive private and public libraries existed in Greece and Rome, but all have perished except those exhumed from Herculaneum.

Bd. i. 1; Chabas, *Pap. d'Harris* (Chalon, 1860); *Papyrus Hieratiques* (8vo, Chalon, 1863); *Voyage d'un Egyptien* (1866); Pleyte, *Papyrus de Turin* (1869—1874); *Cambridge Essays* (1858), p. 227; De Rougé, *Rev. Contemp.* xxvii. p. 389; Devens, *Papyrus Judicione de Turin* (1868); *Trans. Soc. Bibl. Arch.* (1874).

PAPYRUS, a genus of plants of the natural order *Cyperaceæ*, of which there are several species, the most important being the EGYPTIAN P. or *Papyrus* of the ancients (*P. antiquorum*, *Cyperus papyrus* of Linnaeus); a kind of sedge, 8 to 10 feet high; with a very strong, woody, aromatic, creeping root; long, sharp-keeled leaves; and naked, leafless, triangular, soft, and cellular stems, as thick as a man's arm at the lower part, and at their upper extremity bearing a compound umbel of extremely numerous drooping spikelets, with a general involucre of 8 long filiform leaves, each spikelet containing 6—13 florets. By the ancient Egyptians it was called *papu*, from which the Greek *papyrus* is derived, although it was also called by them *byblos* or *deltos*. The Hebrews called it *gomé*, a word resembling the Coptic *gom*, or volume; its modern Arabic name is *Berdé*. So rare is the plant in the present day in Egypt, that it is supposed to have been introduced either from Syria or Abyssinia; but it has been seen till lately in the vicinity of the Lake Menzaleh, and specimens sent to England;

and as it formerly was considered the emblem of Northern Egypt, or the Delta, and only grown there if introduced, it must have come from some country

Papyrus (*P. antiquorum*).

lying to the north of Egypt. It has been found in modern times in the neighbourhood of Jaffa, on the banks of the Anapus, in the pools of the Liane, near Syracuse, and in the vicinity of the Lake Thrasymenus. It is represented on the oldest Egyptian monuments, and as reaching the height of about ten feet. It was grown in pools of still water, growing ten feet above the water, and two beneath it, and restricted to the districts of Sais and Sebennytus. The P. was used for many purposes both ornamental and useful, such as crowns for the head, sandals, boxes, boats, and cordage, but principally for a kind of paper called by its name. Its pith was boiled and eaten, and its root dried for fuel. The papyrus or paper of the Egyptians was of the greatest reputation in antiquity, and it appears on the earliest monuments in the shape of long rectangular sheets, which were rolled up at one end, and on which the scribe wrote with a reed called *kash*, with red or black ink made of an animal carbon. The process of making paper from the papyrus is described in the article PAPER. When newly prepared, it was white or brownish white and lissom; but in the process of time, those papyri which have reached the present day have become of a light or dark brown colour, and exceedingly brittle, breaking to the touch. While papyrus was commonly used in Egypt for the purposes of writing, and was, in fact, the paper of the period, although mentioned by early Greek authors, it does not appear to have come into general use among the Greeks till after the time of Alexander the Great, when it was extensively exported from the Egyptian ports under the Ptolemies. Fragments, indeed, have been found to have been used by the Greeks centuries before. It was, however, always an expensive article to the Greeks, and a sheet cost more than the value of a dollar. Among the Romans, it does not appear to have been in use at an early period, although the Sibylline books are said to have been written on it, and it was cultivated in Calabria, Apulia, and the marshes of the Tiber. But the staple was no doubt imported from Alexandria, and improved or adapted by the Roman manufacturers. So extensive was the

Alexandrian manufactory, that Hadrian, in his visit to that city, was struck by its extent; and later in the empire, an Egyptian usurper (Firmus, 272 A.D.) is said to have boasted that he could support an army off his materials. It continued to be employed in the Eastern and Western Empire till the 12th c., and was used amongst the Arabs in the 8th; but after that period, it was quite superseded by parchment. At the later periods, it was no longer employed in the shape of rolls, but cut up into square pages, and bound like modern books.

As a matter of scientific interest, experiments on the manufacture of paper from the P. have been made in recent times by Landolina, Seyffarth, and others.—Another species of P. (*P. corymbosus* or *P. Pangorei*) is much used in India for making mats. See INDIAN GRASS MATTING.

PAR, or PARR, a small fish, also called BRANDLING and FINGERLING in different parts of Britain, inhabiting rivers and streams, and at one time believed to be a distinct species of the genus *Salmo*, but now almost universally regarded as the young of the salmon. The question will be noticed in the article SALMON. It may here, however, be mentioned, that it is difficult to discriminate the young of different species of this genus. The par rises with extraordinary readiness to the artificial fly; and until it began to receive protection as the fry of the salmon, vast numbers were killed both by youthful and adult anglers.

PARA', or BELEM, a thriving city and seaport of Brazil, capital of the province of the same name, stands on the east bank of the river Para, 80 miles from its mouth. Lat. 1° 28' S., long. 48° 28' W. The harbour is formed by an abrupt curve or inlet of the channel of the river, which is here 20 miles broad. Vessels of large size are admitted; but the anchorage, though safe, has of late years become increasingly difficult of access, owing to the approaches getting silted up. The streets are paved and macadamised, but are for the most part in bad repair; the houses, like those of most Brazilian towns, have whitened walls and red-tiled roofs. Among the principal buildings are the palace, the cathedral, and the churches. There are also numerous public squares, a college, and a beautiful botanic garden. The city is supplied with water by water-carts that perambulate the streets. The 'Amazon Navigation Company,' a Brazilian association, has erected large workshops, coal depôts, and wharfs; and steam navigation is rapidly extending. The imports have an annual value of about 5,000,000 dollars; the annual exports reach nearly 8,000,000 dollars, of which about 6,000,000 are for india-rubber. The imports are principally cotton manufactures, wheat and flour, outlery and hardware, wool, gold and silver wares, coins, and wine. The exports are india-rubber, coffee, sugar, raw cotton, hides, tobacco, diamonds, and cocoa. Pop. 35,000. P. is the mart through which passes the whole commerce of the Amazon and its affluents. The city was the seat of revolution during the whole of the year 1835, when a great number of lives were lost and houses destroyed, and grass grew in streets that previously had been the centre of business. It is only since the year 1848 that the city can be said to have fairly entered upon the path of orderly commercial progress; and since that period, its advance has been continuous and rapid.

PARA', an important province of the empire of Brazil, in the extreme north of the country, is bounded on the N. by Guiana and the Atlantic, on the E. by Maranhão and Goyas, on the S. by Matto Grosso, and on the W. by Amazonas. Area, 460,000

square miles; pop. (1882) 330,000. It is one of the largest provinces of Brazil—having an area nearly twice the extent of Austria—is watered by the Amazon and its great affluents the Tapajós, Xingú, and Tocantins; and forms a portion of a district—the Amazon Valley—which has been described by the most thorough explorer of this region as unequalled for richness of vegetable production and fertility of soil. The surface of the country is level, and consists of great plains, intersected by rivers, and covered with primeval forests, and in some cases with rich pasture. The climate, though warm, is not unhealthy. The precious metals, with diamonds, iron, and coal, are found, but are not worked. The timber is valuable, and the chief crops raised upon the very limited area as yet brought under cultivation are coffee, rice, millet, and cotton.

PARA', the name of the south arm of the Amazon, forming an outlet for that river into the Atlantic, on the southern side of the island of Marajo (q. v.). It is 200 miles in length, is 20 miles broad opposite the city of Para, and is 40 miles broad at its mouth. Its most important affluent, and the source whence it draws, perhaps, the great mass of its volume of waters, is the Tocantins. Formerly, the name Para, which is said to signify 'father of waters,' was applied in a general way to the river Amazon. At the time of the spring-tides, the bore rushes up the river with enormous force, forming a wave 15 feet high.

PARA', a coin of copper, silver, or mixed metal, though most generally of copper, in use in Turkey and Egypt; it is the 40th part of a piastre, is divided into 3 aspers, and varies much in value, owing to the debased and complicated condition of the Turkish coinage. Pieces of 5 paras are also in use. The para is equal to about $\frac{1}{16}$ th of a penny sterling in Turkey, and $\frac{1}{16}$ th of a penny sterling in Egypt. See PIASTRE.

PARA GRASS. See PIASSABA.

PARABLE (Gr. *parabolé*, a comparison) was originally the name given by the Greek rhetoricians to an illustration avowedly introduced as such. In Hellenistic and New Testament Greek, it came to signify an independent fictitious narrative, employed for the illustration of a moral rule or principle. This kind of illustration is of Eastern origin, and admirable examples are to be found in the Old and New Testaments, particularly in the discourses of our Lord. It is no less interesting than curious to learn that many of Christ's parables, or at least much of his parabolic imagery, are to be found in the writings of Hillel, Shammai, and other great rabbis, as, for example, the parables of the Pearl of Great Price, the Labourers, the Lost Piece of Money, the Wise and Foolish Virgins, &c. Among modern writers, the German divine Krummacher (q. v.) has greatly distinguished himself in this species of composition. The parable differs from the Fable (q. v.) in the probability or verisimilitude of the story itself, and agrees with it in the essential requisites of simplicity and brevity. In the course of time, the word parable came to lose its significance of figurative speech, and to mean speech generally. From the *parabola* of the Latin Vulgate, came the medieval Latin *parabolare*, whence the modern French *parler* and *parole*. An excellent work on the parables of the New Testament—probably the best in the English language—is that by Archbishop Trench.

PARABOLA, one of the conic sections, is produced by a plane not passing through the vertex, which cuts the cone in a direction parallel to that of a plane touching the convex surface of the cone. A little consideration will show that

a section so produced cannot be a closed curve, but its two branches, though continually widening out from each other, do not diverge so rapidly as in the Hyperbola (q. v.). The nearer the cutting plane is to that which touches the cone, the less do the two branches diverge; and when the two planes coincide, the branches also coincide, forming a straight line, which is therefore the limit of the parabola. It may otherwise be considered as a curve, every point of which is equally distant from a fixed straight line and a given point; the fixed straight line is called the *directrix*, and the given point the *focus*. Thus (see fig.) PAP' is a parabola.

The diagram shows a parabola opening to the right. The vertex is labeled A. A horizontal line segment AE represents the axis of symmetry, extending to the right from A. A point S is located on the axis to the left of A, representing the focus. A vertical line segment BN passes through S, with B at the top and C at the bottom. A point P is on the upper part of the parabola, and a point P' is on the lower part. A line segment PS connects the focus S to point P. A horizontal line segment PD is drawn from P to the vertical line BC, such that PD is perpendicular to BC. A line segment SE is drawn from the focus S perpendicular to the vertical line BC, meeting it at E. The diagram illustrates the property that PS = PD.

perpendicular from the focus to the directrix. All lines in a parabola which are parallel to the axis cut the curve in only one point, and are called *diameters*. All lines, such as PP', which cut the curve in two points, are ordinates, and the diameter to which they are ordinates, is that one which bisects them; the portion of this diameter which is intercepted between the ordinate and the curve, is the corresponding abscissa. From the property of the parabola that PS = PD, the equation to the curve may be at once deduced; for PS = PD = EN, therefore PS² (which = PN² + NS²) = EN²; hence PN² = EN² - NS² = (ES + SN)² - NS² = ES² + 2ES.SN = (since ES = 2AS) 4AS² + 4AS.SN = 4AS(AS + SN) = 4AS.AN; and calling PN, the semiordinate, y; AN, the abscissa, x; and AS, a, the equation to the parabola becomes y² = 4ax, where a (the distance of the vertex from the focus) remains the same for all points in the same curve. It is evident from the equation, as well as from the geometrical derivation of the parabola, that it must have two, and only two branches, and that the further it is extended the nearer its branches approach to the condition of straight lines parallel to the axis, though they never actually become so. The parabola has no asymptotes, like the hyperbola, but it possesses many properties which are common to it with that curve and the ellipse. In fact, the parabola is nothing more than an ellipse, whose major axis is infinitely long.

If parallel rays of light or heat fall upon the concave surface of a paraboloid (see PARABOLOID mirror), they are reflected to the focus, and conversely, if a light be placed in the focus of a paraboloid reflector, its rays will be reflected in parallel directions, and would appear equally bright at all distances did light move without deviation, and unabsorbed. Also, if a body be projected in a direction not vertical, but inclined to the direction of gravity, it would, if undisturbed by the resisting force of the atmosphere, describe accurately a

parabola whose axis is vertical, and whose vertex is the highest point reached by the body (see PROJECTILES).

The term parabola is used in analysis in a general sense, to denote that class of curves in which some power of the ordinate is proportional to a lower power of the abscissa. Thus, the curve we have just described, and which is distinguished as the *common* or Apollonian parabola, has the square of its ordinate proportional to its abscissa; the *cubical* parabola has the cube of its ordinate proportional to its abscissa; and the *semi-cubical* parabola has the cube of its ordinate proportional to the square of its abscissa.

PARABOLANI (Gr. *parabolas*, a desperate person), a class of functionaries in the early church, by some writers reckoned as members of the clergy, and included in the ranks of the minor orders, but more probably religious associations, whose duty it was to assist the clergy, especially in the more laborious and the menial offices of religion or of charity. The etymology of the name is somewhat curious, being derived or applied from that of those desperate adventurers of the arena who hired themselves for the wild-beast fights of the amphitheatre. The chief duty of the parabolani was the tending of the sick, whether in ordinary diseases or in times of pestilence. By some, the association is believed to have originated at Alexandria, and perhaps to have been peculiar to that church; but although the parabolani were certainly very numerous at Alexandria, amounting to some 500 or 600, it is beyond all question that they were also enrolled in other churches. We find them at Ephesus, at the time of the council in 449. They held the same place in regard of ministrations to the living, that the *Fossores* of Rome or the *Kopistai* of the Greeks did in relation to the burial of the dead. The parabolani are made the subject of formal legislation by Theodosius the younger. At first they were subject to the *Præfectus Augustalis*, but a later decree placed them directly under the authority of the bishop.

The name *parabolani* must not be confounded with the epithet *parabolarius*, which the pagans applied to the Christian martyrs, from the recklessness with which they gave their lives for their faith.

PARABOLOID, a solid figure traced out by a Parabola (q. v.) revolving round its principal axis. Sections of this solid parallel to the principal axis are parabolas, and those perpendicular to it, circles. The term 'paraboloidal,' for which 'parabolic' is frequently but improperly substituted, is applied either to bodies having the form of a paraboloid, or to concave surfaces which seem to have taken their peculiar hollow shape from the impress of a paraboloidal body.

PARACELSUS. About the end of the 15th c. there lived in the small town of Marien-Einsiedeln, near Zurich in Switzerland, William Bombast von Hohenheim, a physician and chemist; he was married to the lady-superintendent of the hospital attached to the convent of Einsiedeln; they had an only son, Philip Aureolus Theophrastus, born, it is thought, about 1493. The name Paracelsus, by which he is now known, is a rude rendering into Greek and Latin of his patronymic. It seems doubtful if he ever attended any regular school, but he received from his father the rudiments of Latin, and whatever else he could teach. He soon took to roaming, and even pursued his travels into Asia and Africa. How he maintained himself during his pilgrimage is unknown; probably by necromancy and quack cures—that is, proclaiming he had certain specifics, and bargaining for the amount he was to

receive if he performed a cure. He was a diligent chemist, investigating the processes of the preparation of metals, and making experiments as to their medicinal virtues; also to discover the philosopher's stone. As a chemist he lived with Sigismund Fugger, one of a family celebrated for its patronage of art and science. His cures, real or pretended, became noised abroad, and he was called to prescribe for all the great men of his day. When he was thirty-three, he boasted of having cured thirteen princes, whose cases had been declared hopeless. He was then at his zenith, and at the recommendation of Ecolampadius was appointed professor of physic and surgery at Basel. He commenced his academic career by publicly burning Galen's works, exclaiming Galen did not know as much as his shoe-latchets. 'Reading never made a physician,' he said; 'countries are the leaves of nature's code of laws—patients his only books.' His class-room at first was full to overflowing, but was soon deserted, and he fell into habits of excessive intemperance; indeed his secretary asserts he was drunk every day; never undressed, and went to bed with his famous sword by his side, which he would draw, and flourish about the room. The reason of his departure from Basel was, that a certain dignity, suffering from gout, in his agony sent for Paracelsus, and promised to give him 100 florins if he cured him. Paracelsus gave him three *laudanum* pills; the canon felt comfortable, and the doctor claimed his fee, but the churchman refused to pay. Paracelsus took him into court, but the judge decided against the professor, who lost his temper, and abused the legal functionary in such a manner that the matter was taken up by the town council, and ended in the expulsion of Paracelsus. He recommenced his wanderings. Wherever he went he excited the regular faculty to a state of violent hatred, not wholly undeserved. At Salzburg he had given offence in the usual way, and the result was, 'he was pitched out of the window at an inn by the doctor's servants, and had his neck broken by the fall.' This took place in 1541.

That a man whose life was such an incoherent medley should exert an influence for centuries after his death, may well be a matter of surprise, but he and the age were fitted for each other. He struck the weak point of the prevailing system of medicine; he appealed to the public as to whether it were not a false system that could only lead to failure, and he proposed a system of his own, which, though shrouded in absurdity and obscurity, inaugurated a new era of medicine. The prominent idea of his system is, that disease does not depend upon an excess or deficiency of bile, phlegm, or blood, but that it is an actual existence, a blight upon the body subject to its own laws, and to be opposed by some specific medicine. See the works of Paracelsus; also of Schulz (1831); Lessing (1839); Mook (1876); Russell (1861); also Browning's famous poem on P.

PARACHUTE (Fr. *chute*, a fall), a machine invented for the purpose of retarding the velocity of descent of any body through the air, and employed by aeronauts as a means of descending from balloons. It is a gigantic umbrella, strongly made, and having the outer extremities of the rods, on which the canvas is stretched, firmly connected by ropes or stays to the lower part of the handle. The handle of the parachute is a hollow iron tube, through which passes a rope connecting the balloon above with the car (in which are the aeronauts and their apparatus) beneath, but so fastened, that when the balloon is cut loose, the car and parachute still remain connected. When the balloon ascends, the parachute collapses like an umbrella; but when the balloon

rope is severed, and the car begins to descend, the parachute is extended by the action of the air, and prevents the car from acquiring a dangerous velocity of descent; the final velocity in those cases where the machine is of a size proportioned to the weight it has to support, being no more than would be acquired by a person leaping from a height of between two and three feet. But the slightest derangement of the parachute's equilibrium, such as might be caused by a breath of wind, or the smallest deviation from perfect symmetry in the parachute itself, immediately produces an oscillatory motion of the car, having the apex of the parachute as a centre, and the oscillations becoming gradually greater and more rapid, the occupants of the car are in most cases either pitched out, or are along with it dashed on the ground with frightful force. This defect in the parachute has been attempted to be remedied in various ways, but hitherto without success. The first successful experiment with the parachute was made by Blanchard at Strasburg in 1787, and the experiment has been often repeated by Garnerin and others; very frequently, however, with fatal results.

The parachute was employed by Captain Boxer, R.N., as an essential part of his patent light-ball, for discovering the movements of an enemy at night, and was so arranged as to open up when the lighted ball had attained its greatest elevation, so as to keep it for a considerable period almost suspended in the air.

PARADE (from *parare*) signified in its original sense a prepared ground, and was applied to the courtyard of a castle, or to any enclosed and level plain. From the practice of reviewing troops at such a spot, the review itself has acquired the name of parade. In its modern military acceptation, a *parade* is the turning out of the garrison, or of a regiment in full equipment, for inspection or evolutions before some superior officer. It is the boast of British troops that their line and discipline are as perfect under an enemy's fire as on the parade ground.

PARADISE. See EDEN.

PARADISE, BIRD OF. See BIRD OF PARADISE.

PARADOS—another name for Traverse—is an intercepting mound, erected in various parts of a fortification for the purpose of protecting the defenders from a rear or ricochet-fire. See FORTIFICATION.

PARADOX (Gr. *para*, beside, or beyond, and *doxa*, an opinion), a term applied to whatever is contrary to the received belief. Cicero, in his book on paradoxes, states that the Stoics called by this name all those unusual opinions which contradict the notions of the vulgar. It follows from this that a paradox is not necessarily an opinion contrary to truth. There have been bold and happy paradoxes whose fortune it has been to overthrow accredited errors, and in the course of time to become universally accepted as truths. It is, perhaps, even one of the prerogatives of genius to bring such into the world, and thereby to alter the character of an art, a science, or a legislation; but this, the highest form of paradox, which is only another name for originality of thought, or for novelty of scientific discovery, is rare. The paradox which springs from a passion for distinction, and which, in its efforts to achieve it, despises good sense and the lessons of experience, is far more frequent. It may not be at bottom a positive error in thought, but it is so exaggerated in expression, that if taken literally it actually does mislead. This is the besetting sin of the brilliant and epigrammatic class of writers,

abundant examples of which are to be found in modern French literature.

PARAFFIN is the name given to several closely-allied substances, which are composed of mixtures of polymeric hydrocarbons, of the olefant gas series (that is to say, of the formula $C_m H_{2m}$), and are obtained from the dry distillation of wood, peat, bituminous coal, wax, &c. P. is particularly abundant in beech tar, but according to Reichenbach, to whom its name (which is formed from *parum affinis*, 'little allied,' in consequence of its resisting the action of the strongest acids and alkalies) is due, and who may be regarded as its discoverer; it is also found in the tar of both animal and vegetable substances. At ordinary temperatures paraffin is a hard, white, crystalline substance, devoid of taste or odour, and resembling spermaceti, both to the touch and in appearance. The paraffin obtained from wood fuses at about 111° , but the varieties obtained from other substances have considerably higher boiling-points. When carefully heated, it sublimes unchanged at a little below 700° . It dissolves freely in hot olive oil, in oil of turpentine, in benzol, and in ether, but it is only slightly soluble in boiling alcohol, and is quite insoluble in water. It does not burn readily in the air, unless with the addition of a wick, when it evolves so brilliant and smokeless a flame that it has been applied to the manufacture of candles, which rival those made of the finest wax. Much of the paraffin of commerce is obtained in this country, from the Boghead cannel-coal, and from the bituminous shale of West Lothian and other districts. See NAPHTHA, SHALE, PETROLEUM, OIL WELLS in SUPP., Vol. X.

PARAFFIN OIL is the term applied to the oily matter which is given off in large quantity in the distillation of cannel-coal and bituminous shale. By rectification it may be separated into three portions, one of which remains liquid at very low temperatures, boils at about 420° , and is much used under a variety of names for illuminating purposes, while a mixture of the two less volatile portions (which may be regarded as composed of paraffin dissolved in a mixture of hydrocarbons of nearly the same composition as paraffin) is largely employed for the purpose of lubricating machinery, for which it is admirably adapted by its power of resisting the oxidizing action of the atmosphere, and by its very slow evaporation. See NAPHTHA.

PARAGUAY, a republic of South America. Its frontiers, previous to the war of 1865—1870, were not well defined, but on its conclusion were fixed by treaty. P. now extends from 22° to 27° 35' S. lat., and from 54° 35' to 61° 40' W. long., forming the peninsula between the rivers Paraguay and Parana. It is bounded N. and N.E. by Brazil, S.E., S., and S.W. by the Argentine Confederation, and N.W. by Bolivia. Its area is estimated at 91,970 square miles. In 1857, before the war, the population was estimated at 1,337,439, consisting of whites of Spanish descent, native Indians, negroes, and a mixture of these several races. In 1873, it had fallen to 221,079; in 1876, it was 293,844; and in 1879, exclusive of some 130,000 Indians, it was 346,048, nearly two-thirds of whom were females. A mountain-chain called Sierra Amambay, running in the general direction of from north to south, and bifurcating to the east and west towards the southern extremity, under the name of Sierra Maracayú, divides the tributaries of the Parana from those of the Paraguay, none of which are very considerable, although they are liable to frequent and destructive overflows. The northern portion of P. is in general undulating, covered by low, gently-swelling ridges, separated by large grass

plains, dotted with palms. There are mountains in the north-east and north-west corners. The southern portion is one of the most fertile districts of South America, consisting of hills and gentle slopes richly wooded, of wide savannas, which afford excellent pasture-ground, and of rich alluvial plains, some of which, indeed, are marshy, or covered with shallow pools of water (only one lake, that of Ypao, deserving special notice), but a large proportion are of extraordinary fertility and highly cultivated. The banks of the rivers Parana and Paraguay are occasionally belted with forest; but, in general, the low lands are destitute of trees. The climate, for a tropical country, is temperate, the temperature occasionally rising to 100° in summer, but in winter being usually about 45° . In geological structure, the southern part belongs generally to the tertiary formation; the north and east presenting greywacke rocks in some districts. The natural productions are very varied, although they do not include the precious metals or other minerals common in South America. Much valuable timber is found in the forests, and the wooded districts situated upon the rivers possess a ready means of transport. Among the trees are several species of dye-wood, several trees which yield valuable juices, as the India-rubber and its cognate trees; and an especially valuable shrub, called the *Maité* (q. v.), or Paraguay tea-tree, which forms one of the chief articles of commerce, being in general use throughout La Plata, Chili, Peru, and other parts of South America. The tree grows wild in the north-eastern districts, and the gathering of its leaves gives employment in the season to a large number of the native population. Many trees also yield valuable gums. Wax and honey are collected in abundance, as is also cochineal, and the medicinal plants are very numerous. The chief cultivated crops are maize, rice, coffee, cocoa, indigo, mandioc, tobacco, sugar-cane, and cotton. Nearly three-fourths of the land is national property, consisting partly of the lands formerly held by the Jesuit missions, partly of lands never assigned to individuals, partly of lands confiscated in the course of the revolutionary ordeal through which the country has passed. The national estates have, for the most part, been let out in small tenements, at moderate rents. Under the dictator Francia (1814—1840), agriculture made considerable progress, and the breed of cattle and horses was much improved, and the stock increased. The few manufactures are sugar, rum, cotton and woollen cloths, and leather. The commerce of the country is chiefly in the hands of the government, which holds a monopoly of the export of P. tea. In 1880, the total value of the exports was £252,000; of imports, somewhat less. The chief exports were maté, tobacco, hides, oranges, and bark for tanning; imports, cotton goods, wine, grain, rice, linen, silk, petroleum, &c. Till the war of 1865—1870, P. had no national debt, but its terrible losses compelled it then to contract obligations amounting to upwards of £47,000,000. Three millions were contracted in England on the security of the public lands of P., estimated at upwards of £19,000,000; but payment of interest and sinking fund ceased in 1874, and prior to that was paid directly out of the capital. The military force, which, during the five years' war, was raised to 60,000 men, has now been reduced to 500. The established religion is the Roman Catholic, the ecclesiastical head of which is the Bishop of Asuncion. Education is very widely diffused; and it is said that there are but few of the people who are not able to read and write.

The history of P. is highly interesting. It was discovered by Sebastian Cabot in 1526, but the first colony was settled in 1535 by Pedro de Mendoza, who

founded the city of Asuncion, and established P. as a province of the viceroyalty of Peru. The warlike native tribe of the Guaranis, however, a people who possessed a certain degree of civilisation, and professed a dualistic religion, long successfully resisted the Spanish arms, and refused to receive either the religion or the social usages of the invaders. In the latter half of the 16th c., the Jesuit missionaries were sent to the aid of the first preachers of Christianity in P.; but for a long time they were almost entirely unsuccessful, the effect of their preaching being in a great degree marred by the profligate and cruel conduct of the Spanish adventurers, who formed the staple of the early colonial population. In the 17th c. the home government consented to place in their hands the entire administration, civil as well as religious, of the province; which, from its not possessing any of the precious metals, was of little value as a source of revenue; and in order to guard the natives against the evil influences of the bad example of European Christians, gave to the Jesuits the right to exclude all other Europeans from the colony. From this time forward the progress of civilisation as well as of Christianity was rapid. The legislation, the administration, and the social organisation of the settlement were shaped according to the model of a primitive Christian community, or rather of many communities under one administration; and the accounts which have been preserved of its condition, appear to present a realisation of the ideal of a Christian Utopia. On the expulsion of the Jesuits from P. in 1768, the history of which is involved in much controversy, the province was again made subject to the Spanish viceroys. For a time the fruits of the older civilisation maintained themselves; but as the ancient organisation fell to the ground, much of the work of so many years was undone; the communities lapsed into disorganisation, and by degrees much of the old barbarism returned. In 1776, P. was transferred to the newly-formed viceroyalty of Rio de La Plata; and in 1810 it joined with the other states in declaring its independence of the mother kingdom of Spain, which, owing to its isolated position, it was the earliest of them all to establish completely. In 1814, Dr Francia (q. v.), originally a lawyer, and the secretary of the first revolutionary junta, was proclaimed dictator for three years; and in 1817, his term of the office was made perpetual. He continued to hold it till his death in 1840, when anarchy ensued for two years; but, in 1842, a national congress elected two nephews of the dictator, Don Alonso and Don Carlos Antonio Lopez, joint consuls of the republic. In 1844, a new constitution was proclaimed, and Don Carlos was elected sole president, with dictatorial power, which he exercised till his death in 1862, when he was succeeded by his son, Don Francisco Solano Lopez, whose name has become notorious in connection with the tragic struggle of 1865—1870, in which the Paraguayans made a heroic but unavailing fight against the combined forces of Brazil, the Argentine Confederation, and Uruguay. The war was brought to a close by the defeat and death of Lopez at the battle of Aquidaban, March 1st 1870. In June 1870, a congress voted a new constitution, which was proclaimed on the 25th Nov. It is modelled on that of the Argentine Confederation, the legislative authority being vested in a congress of 2 houses, and the executive in a president, elected for 6 years. P. was till 1876 partially occupied by Brazilian troops, and was virtually a Brazilian province.

The central department, in which the capital, Asuncion, is situated, contains nearly one-third of the whole inhabitants; and the capital itself,

10,000 to 20,000. Asuncion is connected by railway with Paraguari. The inhabitants of the towns consist chiefly of whites, or of half-breeds, speaking Spanish. The native population of the provinces are chiefly Guaranis, speaking the Guaraní language.

PARAGUAY, an important river of South America, an affluent of the Parana (q. v.), rises in the Brazilian province of Matto Grosso, on a plateau of red sandstone, in lat. 13° 30' S., long. about 55° 50' W., 9535 feet above sea-level. The sources of the river are a number of deep lakes, and eight miles from its source, the stream already has considerable volume. Pursuing a south-west course, and after flowing through a level country covered with thick forests, the P. is joined from the west by the Jauru, in lat. 16° 30' S. It then continues to flow south through the Marsh of Xarayes, which, during the season when the stream rises, is an expansive waste of waters, stretching far on each side of the stream, and extending from north to south over about 200 miles. The river still pursues a circuitous but generally southward course, forming from 20° to 22° S. the boundary-line between Brazil and Bolivia, thence flowing south-south-west through the territories of Paraguay to its junction with the Parana, in lat. 27° 17' S., a few miles above the town of Corrientes. Its chief affluents are the Cuyaba, Tacuary, Mondego, and Apa on the left, and the Jauru, Pilcomayo, and Vermejo on the right. Except in the marshy districts, the country on both banks of the river is rich and fertile, and abounds in excellent timber. The entire length of the river is estimated at 1800 miles; it is on an average about half a mile in width, and is navigable for steamers to the mouth of the Cuyaba, 100 miles above the town of Corumba. The waters of the P., which are quite free from obstructions, were declared open to all nations in 1852; and now Brazilian mail-steamers ply monthly between Monte Video and Cuyaba, on the river of the same name, one of the head-waters of the P.; and there are several lines of steamers between Buenos Ayres and Asuncion.

PARAGUAY TEA. See *Miré*.

PARAHIBA, one of the most eastern maritime provinces of Brazil, bounded on the N. by Rio Grande do Norte, on the S. by Pernambuco, on the W. by Ceara, and on the E. by the Atlantic. Area, 31,600 sq. m.; pop. (1872) 376,226. It is traversed by a river of the same name, by a number of smaller streams, and by mountainous ridges, between which are valleys, the soils of which are, for the most part, dry and sandy. Cotton of excellent quality, mandioc, and tobacco are grown; and cotton, sugar, and timber are exported. Capital, Parahiba (q. v.).

PARAHIBA, a seaport of Brazil, capital of the province, and situated on the river of the same name, about 10 miles from the sea. Besides the cathedral, it contains a number of religious houses, two colleges, and other educational institutions. The port is good for small vessels, and the coasting-trade is large. Pop. 15,000.

PARALLAX is the apparent displacement of an object caused by a change of place in the observer. When an object at M is looked at from P, it

Fig. 1.

appears in line with some object, S; but after the observer has moved to E, M has apparently retro-

graded to a position in line with S' ; this apparent retrogression is denominated *parallax*. The angle PME is called the 'angle of parallax,' or the 'parallactic angle,' and is the measure of the amount of parallax. To astronomers, the determination of the parallax of the heavenly bodies is of the utmost importance, for two reasons—first, from the necessity of referring all observations to the earth's centre, i.e., so modifying them as to make it appear as if they had been actually made at the earth's centre; and secondly, because parallax is our only means of determining the magnitude and distance of the heavenly bodies. The *geocentric* or *daily* parallax—as the apparent displacement of a heavenly body, due to its being observed from a point on the surface of the earth instead of from its centre, is called—is determined as follows: Let P and P' be two stations on the surface of the earth (fig. 2), E its

Fig. 2.

centre, M the object to be observed, and Z and Z' the zeniths respectively of the observers at P and P' (points which, if possible, should be on the same meridian exactly); then at P and P' let the *zenith distances*, ZPM and $Z'P'M$, be observed simultaneously, and since the latitudes of P and P' , and consequently their difference of latitude, or the angle PEP' , is known, from these three the angle PMP' (the sum of the parallaxes at P and P') is at once found; and then, by a trigonometrical process, the separate angles or parallaxes PME and $P'ME$. When the parallax of M , as observed from P , is known, its distance from E , the centre of the earth, can be at once found. When the heavenly body is on the horizon, as at O , its parallax is at a maximum, and is known as the *horizontal parallax*. The geocentric parallax is of use only in determining the distances of those heavenly bodies at which the earth's radius subtends a considerable angle; and as the moon and Mars (when in opposition) are the only such bodies, the parallax of the other celestial bodies must be determined in a different manner. The parallax of the Sun (q.v.) is found by observation of the *transit* of Venus across his disk, a much more accurate method than that above described. The parallaxes of the other planets are easily determined from that of Mars.

In the case of the fixed stars, at which the earth's radius subtends an infinitesimal angle, it becomes necessary to make use of a much larger base-line than the earth's radius, and as the largest we can employ is the radius of the earth's orbit, it accordingly is made use of, and the displacement of a star, when observed from a point in the earth's orbit instead of from its centre, the sun, is called the *annual* or *heliocentric* parallax. Here the base-line instead, as in the former case, of being 4000 miles, is about 92,000,000 miles, and the two observations necessary to determine the parallactic angle are made from two points on opposite sides of the earth's orbit, at an interval as nearly as possible of half a year. Yet, notwithstanding the

enormous length of the base-line, it bears so small a proportion to the distances of the stars, that only in three or four cases have they been found to exhibit any parallactic motion whatever, and in no case does the angle of parallax amount to $1''$ (see STARS). The geocentric horizontal parallax of the moon is about $57' 4'' 2$; that of the sun, about $8'' 6$; and of the double star, 61 *Cygni*, the heliocentric parallax has been determined by Bessel to be $348''$, equivalent to about 15 millionths of a second of geocentric horizontal parallax. Parallax affects every observation of angular measurement in the heavens, and all observations must be corrected for parallax, or, in astronomical phrase, referred to the earth's centre before they can be made use of in calculation. The position of a body, when noted from the surface of the earth, is called its *apparent* position; and when referred to the centre, its *real* position.

PARALLEL FORCES are those forces which act upon a body in directions parallel to each other. Every body, being an assemblage of separate particles, each of which is acted on by gravity, may thus be considered as impressed upon by a system of parallel forces. The following demonstration will exhibit the mode in which the amount and position of the resultant force are found: Let P and Q be two parallel forces acting at the points A and B respectively, either in the same (fig. 1) or in opposite (fig. 2) directions; join AB , and in this line, at the points A and B , apply the equal and opposite forces S and S , which counterbalance each other, and therefore do not affect the system. Find M and N (see COMPOSITION AND RESOLUTION OF FORCES), the resultants of P and S , and Q and S respectively, and produce their directions till they meet in D , at which point let the resultants be resolved parallel to their original directions; then there are two equal forces, S and S , acting parallel to AB , but in opposite directions, and thus, as they counterbalance each other, they may be removed. There then remain two forces, P and Q , acting at D , in the line DC , parallel to their original directions, and their sum (fig. 1) or difference (fig. 2), represented by R , is accordingly the resultant of the

Fig. 1.

Fig. 2.

original forces at A and B . To find the position of C , the point in AB , or AB produced, through which the resultant passes, it is necessary to make use of the well-known property denominated the *Triangle of Forces* (q.v.), according to which the three forces S , M , and P are proportional to the lengths of AC , AD , DC , the sides of the triangle ADC ; then $S : P :: AC : CD$, similarly $Q : S :: DC : CB$, therefore $Q : P :: AC : BC$,

and $Q \pm P$ or $R : P :: AC \pm BC$ or $AB : BC$, from which proportions we derive the principle of the lever, $P \times AC = Q \times BC$, and also that $R \times BC = P \times AB$, whence $BC = \frac{P}{R} \times AB$, and the point C is found. The failing case of this proposition is when P and Q acting in opposite parallel directions at different points are equal, in which case the resultant $R = Q - P = Q - Q = 0$. In all other cases there is a progressive motion, such as would be caused by the action of a single force $R (= Q \pm P)$ acting at the point C in the direction CR; but in the failing case, since $R = 0$, there is no progressive motion, but a rotatory movement

Fig. 3.

round the centre of AB. See COUPLE. It is of no consequence whether A and B be the true points of application of the forces P and Q, provided their directions when produced pass through these points, and the point of application of the resultant need not be in the line joining the points of application of the component forces, but its direction must when produced pass through C. If there be more than two parallel forces, the resultant of the whole is found by compounding the resultant of the first two with the third in the way given above, thus obtaining a new resultant, which is similarly combined with the fourth force; and so on till the final resultant is found. The centre of gravity is only a special name for the point of application of the final resultant of a number of parallel forces.

PARALLELEPIPED (Gr.), frequently, but improperly written *Parallelopiped*, is a solid figure having six faces, the faces being invariably parallelograms, and any two opposite faces equal, similar, and parallel. If the faces are all squares, and consequently equal, the parallelepiped becomes a cube. The volume of a parallelepiped is found by multiplying the area of one face by its distance from the opposite one.

PARALLELOGRAM, in Mathematics, is a quadrilateral rectilinear figure which has its opposite sides parallel; the opposite sides are therefore equal, and so are the opposite angles. If one angle of a parallelogram be a right angle, all its angles are right angles, and the figure is then called a *rectangular parallelogram*, or shortly, a *rectangle*; and if at the same time all the sides are equal, the figure is a *square*, otherwise it is an *oblong*. If the angles are not right angles, but all the sides are equal, it is called a *rhombus*; and if the opposite sides only are equal, a *rhomboid*. The two lines which connect the opposite corners of a parallelogram are called its *diagonals*, each bisects the parallelogram, and they bisect each other; the sum of their squares also is equal to the sum of the squares of the sides of the parallelogram.

All parallelograms which have equal bases and equal altitudes are equal in area, whether they be similar in shape or not, and the area of a parallelogram is found by multiplying its base by the height.

PARALLELOGRAM OF FORCES. See COMPOSITION OF FORCES.

PARALLELS, in Military language, are trenches cut in the ground before a fortress, roughly parallel to its defences, for the purpose of giving cover to the besiegers from the guns of the place. The parallels are usually three, with zigzag trenches leading from one to another. The old rule used to be to dig the first at 600 yards distance, but the improvements in artillery have rendered a greater distance necessary; and at Sebastopol, the allies made their first trench 2000 yards from the walls. The third trench is very near to the besieged works, and from it saps and zigzag approaches are directed to the covert-way.—The bearing of parallels in the general conduct of a *SIEGE* will be found described under that head.

PARALLELS or CIRCLES OF LATITUDE are circles drawn round the surface of the earth parallel to the equator. They may be supposed to be the intersections with the earth's surface of planes which cut the earth at right angles to its axis. The greatest of these circles is the equator, which has the centre of the earth for its centre, the radius for its radius, and is equally distant at all points from each pole. It is evident that of the others, those next the equator are greater than those more remote, and that they become less and less till at the poles they vanish altogether. The radius of any one circle is evidently equal to the earth's radius multiplied into the cosine of its latitude or distance from the equator. The rotatory velocity of the earth's surface, which is about $17\frac{1}{2}$ miles per minute at the equator, is only $8\frac{1}{2}$ miles in lat. 60° , in lat. $82\frac{1}{2}^\circ$ (the most northerly point yet reached) is only $2\frac{1}{2}$ miles; and in lat. $89\frac{1}{2}^\circ$ (within 35 miles of the pole) is not more than 267 yards per minute.

The most important parallels of latitude are the *Tropics of Cancer* ($23^\circ 28'$ N. lat.) and *Capricorn* ($23^\circ 28'$ S. lat.), and the *Arctic* ($66^\circ 32'$ N. lat.) and *Antarctic Circles* ($66^\circ 32'$ S. lat.).

PARALYSIS (Gr., a losing or relaxing), or **PALSY**, is a loss, more or less complete, of the power of motion; but by some writers the term is employed to express also loss of sensation. When the upper and lower extremities on both sides, and more or less of the trunk, are involved, the affection is termed *General Paralysis*. Very frequently only one-half of the body laterally is affected, the other side remaining sound; to this condition the term *Hemiplegia* is given. When the palsy is confined to all the parts below an imaginary transverse line drawn through the body, or to the two lower extremities, the condition is termed *Paraplegia*. When one part of the body, as a limb, one side of the face, &c., is exclusively attacked, the affection is known as *local palsy*. In some cases the loss of sensation and the power of motion in the paralysed part is entire, while in others it is not so. In the former the paralysis is said to be *complete*, in the latter, *partial*. In most cases, but not invariably, sensibility and motion are simultaneously lost or impaired. When motion is lost, but sensation remains unimpaired, the affection has received the name of *akinesia* (Gr. *a*, not, and *kinesis*, motion). More rarely, there is a loss of sensibility while the power of motion is retained; and to such cases the term *anesthesia* (Gr. *a*, not, and *aisthesia*, sensation) is applied. This affection occurs most

frequently in the organs of sense; as in the tongue, for example, in which the sense of taste may be lost, without any defect of movement.

Paralysis is in most cases a mere symptom of disease existing in some other part than that apparently affected; as, for example, in the brain or spinal cord, or in the conducting nerves between either of these organs and the palsied organ. Sometimes, however, it is a purely local affection, depending upon a morbid condition of the terminal extremities of the nerves. The varieties in the condition of the brain and spinal cord which occasion paralysis are somewhat numerous; as, for example, congestion, hemorrhagic and serous effusion, softening, fatty degeneration, fibrinous exudation, suppuration, hydatids, various morbid growths, depressed bone from external violence, &c. It is highly probable, also, that palsy may sometimes result from mere functional disorder of the nervous centres—a view which is confirmed by the fact that a *post mortem* examination of a patient who has suffered from this affection sometimes fails to detect any apparent lesion. Paralysis may originate in a nervous trunk, if it is compressed by a tumour, or otherwise mechanically affected, or if it is the seat of morbid action tending in any way to disorganise it; or it may be due to an abnormal condition of the terminations of the nerves, which may be rendered unfit for receiving impressions either from the external world or from the brain by prolonged disuse, by continuous or severe pressure, by exposure to cold, by disorganisation of their own tissue, or by the depressing action of various metallic poisons, especially lead.

We shall briefly notice the symptoms and causes of the most important forms of paralysis, before offering any remarks on the general principles of treatment. *Hemiplegia* (Gr. *hemi*, half, *plēso*, I strike) affects one lateral half of the body, and is that form of palsy to which the term *paralytic stroke* is commonly applied. The parts generally affected are the upper and lower extremities, the muscles of mastication, and the muscles of the tongue on one side. In a well-marked case the patient when seized falls to the ground, all power of motion in the affected arm and leg being lost. The palsy of the face which accompanies hemiplegia is usually quite distinct from the affection known as *facial palsy*, which is an affection of the facial nerve or *portio dura*. See NERVOUS SYSTEM. It is the motor branches of the fifth or trifacial nerve going to the muscles of mastication which are generally involved in hemiplegia, and consequently the cheek is flaccid and hangs down, and the angle of the mouth is depressed on the affected side. The tongue when protruded points towards the paralysed side, and there is often imperfect articulation, in consequence of the lesion commonly affecting the hypoglossal nerve. Hemiplegia may arise from lesions of various kinds, as, for example, (1) from hemorrhage, or some other morbid change in the brain, in which case the palsy is on the side of the body opposite to the lesion, in consequence of the decussation or crossing over of nervous fibres from one side to the other that occurs at the upper part of the Spinal Cord (q. v.); (2) from spinal disease below the point of decussation just noticed; in this case the palsy, and the lesion causing it, are on the same side of the body. It is also sometimes associated with hysteria, epilepsy, and chorea, but in these cases it usually disappears in a few hours.

Paraplegia (Gr.) is usually confined to the two lower extremities, but the muscles of the lower part of the trunk and of the bladder and rectum are sometimes affected. There are at least two distinct

forms of paraplegia, viz. (1) Paraplegia dependent on primary disease of the spinal cord or its membranes, and especially on Myelitis (q. v.); and (2) Reflex Paraplegia, i. e., paraplegia consequent on disease of the kidneys, bladder, urethra, prostate, womb, &c. These two forms of paraplegia differ in many of their phenomena, and the most important of these points of difference have been arranged in a tabular form by Dr Brown Sequard in his *Lectures on Paralysis of the Lower Extremities*, to which we must refer for the best information on this form of palsy. Paraplegia usually comes on slowly, with a gradual increase of its symptoms. The reflex form is, of course, by far the most favourable, as it usually abates spontaneously on the subsidence of the primary disease.

Facial Palsy, although locally affecting only a small part of the body, is a disorder of sufficient importance to require a definite notice. In this affection there is a more or less perfect loss of power over all the muscles supplied by the *portio dura*, or facial nerve. The following graphic account of the appearance of the patient is condensed from Dr Watson's *Lectures on the Practice of Physic*. From one-half of the countenance all power of expression is gone; the features are blank, still, and unmeaning; the eyelids apart and motionless. The other half retains its natural cast, except that, in some cases, the angle of the mouth on that side seems drawn a little awry, in consequence of the want of counterpoise from the corresponding muscular fibres of the palsied side. The patient cannot laugh or weep, or frown, or express any feeling or emotion with one side of his face, while the features of the other may be in full play, nor can he spit or whistle properly. One-half of the aspect, with its unwinking eye, its fixed and solemn stare, might be that of a dead person; the other half is alive and merry. To those who do not comprehend the possible extent of the misfortune, the whimsical appearance of the patient is a matter of mirth and laughter; while, on the other hand, his friends imagine that he has had a stroke, and that he is in a very dangerous state. The nerve may be unable to discharge its duties in consequence of disease within the cavity of the skull, and in that case there is very serious danger; but in the great majority of cases the nervous function is interrupted in that part of the *portio dura* which lies encased in the temporal bone, or in the more exposed part which issues in front of the ear; and hence this form of palsy is generally unattended with any danger to life. It may arise from various causes. Sometimes it is the consequence of mechanical violence, sometimes of tumours pressing on it in the region of the parotid gland, and it very frequently arises from the mere exposure of the side of the face for some time to a stream of cold air.

It yet remains to notice certain kinds of paralysis which differ either in their characters, or in their causes, from those which have been already described—viz., *Shaking Palsy*, or *Paralysis Agitans*; and the palsies induced by various poisons. *Shaking Palsy* has been defined as 'involuntary tremulous motion, with lessened muscular power in parts not in action, and even when supported; with a propensity to bend the trunk forwards, and to pass from a walking to a running pace; the senses and intellect being uninjured.' It is chiefly an affection of old age, and often goes no further than to cause an unceasing nodding and wagging of the head in all directions. Somewhat analogous to this form of palsy is that peculiar kind of trembling which is often noticed in persons who are much exposed to the vapour of mercury; *Mercurial Tremor*, as it is termed by the

physicians, and *The Trembles*, as the patient usually calls it. It consists in a convulsive agitation of the voluntary muscles, especially when an attempt is made to cause them to act under the influence of the will; a patient with this affection walks with uncertain steps, his limbs trembling and dancing as if they had been hung upon wires. When sitting down he exhibits little or no indication of his disease, but on rising he cannot hold his legs steady, nor direct them with precision; and in severe cases he falls to the ground if not supported. The arms are similarly agitated, and the tongue is usually so tremulous as to render the articulation hurried and unnatural. The disease is especially common in artisans employed in the gilding of metals, and particularly of silver, by means of heat; it is also frequent among the workers of quicksilver mines, in which the crude metal is purified by heat. The time required for the production of the disease varies extremely in different cases (according to Dr Watson, from two years to five-and-twenty). The duration of the complaint is considerable; it may last two or three months, or longer, but it is seldom fatal.

The palsy arising from the absorption of lead has been already noticed in the article LEAD-POISONING.

A specific form of paralysis of the lower extremities, consequent on the use of flour from the beans of the *Lathyrus sativus*, is common in certain parts of India and in Thibet. The ripe bean is an ordinary article of food when made into flour, but it is generally used with wheat or barley flour; it is only when it exceeds one-twelfth part that it is at all injurious, and when it exceeds one-third that the paralysis sets in. Other species of *Lathyrus* have been known occasionally to induce similar symptoms in European countries.

We shall enter into no details regarding the treatment of hemiplegia and paraplegia, as the management of these serious affections should be exclusively restricted to the physician. When a patient has an attack of hemiplegia (or a *paralytic stroke*) all that should be done before the physician arrives is to place him in a horizontal position, with the head slightly raised, and to remove any impediments presented by the dress to the free circulation of the blood. Should the physician not arrive in an hour or two, it may be expedient to give the patient a sharp purge (half a scruple of calomel, followed in a few hours by a black draught, if he can swallow; and two drops of croton oil, mixed with a little melted butter, and placed on the back of his tongue, if the power of deglutition is lost), and without waiting for its action, to administer an injection (or clyster) consisting of half an ounce of oil of turpentine suspended (by rubbing it with the yolk of an egg) in half a pint of thin gruel; and cold lotions may be applied to the head, especially if its surface be hot. The question of blood-letting—the universal treatment a quarter of a century ago—must be left solely to the physician. It should, however, be generally known, that if the patient be cold and collapsed; if the heart's action be feeble and intermittent; if there be an anæmic state; if the patient be of advanced age; if there is evidence of extensive disease of the heart or arterial system; or lastly, if there is reason, from the symptoms, to believe that a large amount of hemorrhage has already taken place in the brain; these singly, and *a fortiori* conjointly, are reasons why blood should not be abstracted.

Facial palsy, unless the seat of the disease be within the cavity of the cranium, will usually yield in the course of a few weeks to cupping and blistering behind the ear of the affected side, purgatives, and small doses of corrosive sublimate

(one-twelfth of a grain three times a day, combined with a little of the compound tincture of bark), which must be stopped as soon as the gums are at all affected. Exposure to cold air must be carefully avoided during treatment.

Little or nothing can be done to cure *Paralysis Agitans*. In the treatment of *Mercurial Tremor*, the first step is to remove the patient from the further operation of the poison, while the second is to remove the poison already absorbed into the system, which is effected by the administration of iodide of potassium. This salt combines with the metallic poison in the system, and forms a soluble salt (a double iodide of mercury and potassium), which is eliminated through the kidneys. Good food and tonics (steel or quinia, or the two combined) should be at the same time freely given.

The writer of this article has no personal knowledge of the treatment that should be recommended in the paralysis produced by the use of *Lathyrus sativus*, but cases are reported which seem to have been benefited by good diet, tonics, strychnia, and the application of blisters to the loins.

PARAMAGNETISM, as opposed to Diamagnetism. See DIAMAGNETISM.

PARAMARIBO, the capital of Dutch Guiana, is situated on the western bank of the river Surinam, about 20 miles from its mouth, in 5° 45' N. lat., and 55° 13' W. long. It forms a rectangle of nearly a mile and a half in length by three-quarters in breadth. The streets are broad, covered with shell-sand, and planted on both sides with orange, lemon, tamarind, and other trees. Near the river, the houses, which are chiefly of wood, stand somewhat closely together, but in the remoter parts each is surrounded by its own garden. The rooms are wainscoted with the choicest woods, and elegantly furnished.

In approaching P. from the sea, Fort Zeelandia is first reached; then the Bureau of Finance and Court of Justice on the Government Plain, which is surrounded by stately cabbage-palms; the governor's house, with shady double avenue of tamarind-trees; and lastly, the business streets stretching along the river side. There are a Dutch Reformed, a Lutheran, Moravian, two Roman Catholic churches, and two synagogues. Fort Zeelandia has a large and beautiful barrack, with several roomy houses for the officers. P. has a neat, pleasant, and picturesque appearance, the white painted houses, with bright-green doors and windows, peeping out from the shady trees, and the river being thronged with the tent-boats and canoes which are constantly arriving and departing.

On 1st January 1875, the population amounted to 21,755. By royal decree of 6th February 1851, the flogging of slaves in the Netherlands West Indies was forbidden, except through officers appointed for the purpose, and the number of lashes was limited. This check, however, was frequently evaded, and the greatest barbarities practised, so that the feeling in favour of emancipation increased in the Netherlands, and a bill was passed, 8th August 1862, for emancipating the slaves on the 1st July 1863.

P. is the only port, except Nickerie Point, at the mouth of the Corentyn. In 1870—1880, the number of ships entering the ports of Dutch Guiana varied from 190 to 230 a year, and the tonnage from 20,000 to 25,000 tons. By far the largest number were British. About a fourth part cleared at Nickerie, a very productive portion of the colony, in which sugar, molasses, and rum are manufactured in large quantities.

The climate of D. Guiana is not healthy. From this and other causes the deaths annually exceed the births. Elephantiasis Arabum and Lepra are

fearfully prevalent among the black population of P. and neighbourhood. The rainfall (67 inches) varies much, being smallest at Nickerie, in the west, and largest at Montbyou in the east of the colony (128 inches). Population (1869) 20,373; (1883) 24,485.

As to religion, about 40,000 of the inhabitants of the colony are reckoned Christians, of whom 22,000 are Moravians (mostly converts by missionary agency), 5000 Dutch Reformed (mainly in Paramaribo), 13,000 Catholics. There are about 700 Jews. The Moravian missionaries have missions in the interior, especially amongst the bush-negroes, who speak a language based on broken English, with Dutch, Portuguese, and Indian additions. The colony possesses 60 schools and 5000 pupils, of whom 1300 are in the capital. The great proportion of the births in the colony are illegitimate. The influx of immigrants in 1870-80 varied from 2720 in 1873 to 43 in 1876. The immigrants are mostly from British India.

The coast of Dutch Guiana is an alluvial deposit formed by the rivers and equatorial stream which flows eastwards. Further inland, the soil is diluvial loam, bearing the finest timber trees; and south of this line are extensive savannahs of white sand, stretching towards the hills and mountains of the interior, which are chiefly of gneiss and granite.

The Bank of Surinam, which is the only one in the colony, has its headquarters at P. It has a capital of \$400,000.

PARAMATTA is a light worsted twilled fabric for female dress. It was invented at Bradford, in Yorkshire, and has become an important manufacture of that place. The web consists of combed merino wool, and the warp of cotton. It resembles in texture the Coburg and Orleans cloths.

PARAMATTA, a pleasantly situated town of New South Wales, stands near the west extremity of Port Jackson, on a small river of the same name, and is 15 miles by land west-north-west of Sydney, with which it is connected both by steamer and railway. The houses are mostly detached, and the streets are wide and regular, the principal one being about a mile in length. The institutions comprise churches, schools, an orphan and a lunatic asylum, and a prison. There was formerly an observatory here; but it was removed to Sydney in 1858. 'Colonial tweeds,' 'Paramatta cloths' (first made from wool exported hence) and salt are manufactured. Pop. (1871) 6103; (1881) 8433.

The town of P., formerly called Rosehill, is, after Sydney, the oldest in the colony. It is now always spelt *Paramatta* by Australian authorities.

PARAMETER, or LATUS RECTUM, a term used in conic sections, denotes, in the case of the parabola, a third proportional to the abscissa of any diameter and its corresponding ordinate; in the ellipse and hyperbola, a third proportional to a diameter and its conjugate. The parameter of any diameter is, in the case of the parabola, the same as the double ordinate of that diameter which passes through the focus, and is four times as long as the distance between the diameter's vertex and the directrix. The term parameter was also at one time used to denote any straight line about a curve, upon which its form could be made to depend, or any constant in its equation, the value of which determined the individual curve; but its employment in this sense is now discontinued, except in the theory of homogeneous differential equations, where the constants, for the purpose of aiding the solution, are supposed to vary; and the method is consequently denominated the 'Variation of the Parameters.' In the application of this method to

determine the orbital motions of the planets, the 'seven necessary data' (see ORBIT) were called parameters, but for this the term 'elements' is now substituted.

PARANA', a province in the south of Brazil, is bounded on the N. by the province of São Paulo, on the E. by the Atlantic, S.E. by Santa Catharina, S. by Rio Grande do Sul, W. by Paraguay and Matto Grosso. Area, 85,415 square miles. Pop. (1882) 189,668, of whom 7668 were slaves. The capital is Curitiba, and previously to 1852 this province formed a territory called the Comarca of Curitiba, included in the province of São Paulo. It fully commenced its provincial career in 1853. The sea coast is indented by several bays, but the chief and almost the only port as yet is Paranaguá. A line of mountains runs parallel to the coast at a distance of about 80 miles inland, and throws out spurs and branches westward. The streams flowing east from this water-shed, though numerous, are inconsiderable; while the rivers flowing westward, into the Parana (q. v.), which forms the western boundary of the province, are all about or upwards of 400 miles in length. The principal are the Paranapanema, Ivay, Piquery, and Yguassu. The climate is unusually healthy; the soil is fertile; and agriculture, rearing cattle and swine, and gathering *matté* or Paraguay tea are the chief employments. The capital, Curitiba, has manufactures of coarse woollens, and with its agricultural surroundings has a pop. of 12,000.—The chief port, Paranaguá, on a bay of the same name, is about 400 miles south-west of Rio de Janeiro. It contains about 3000 inhabitants, and exports *matté* to the value of 1,000,000 dollars annually.

PARANA, an important river of Brazil, rises in the province of Minas Geraes, about 100 miles north-west of Rio de Janeiro. It flows west for upwards of 500 miles, through the provinces of Minas Geraes and São Paulo. In the latter it is joined by the Parnahiba, after which its course alters, and it flows south-south-west to Candelaria. Passing this town, it flows west for 200 miles to its confluence with the Paraguay (q. v.), and then bending southward, passes Santa Fe, below which its channel frequently divides and encloses numerous islands. After passing Santa Fe, it rolls onward in a south-east direction, and unites with the Uruguay in forming the Rio de la Plata. Entire length about 2400 miles. It draws a number of considerable tributaries from the province of Parana (q. v.); and of the others, the chief are the Paraguay, Uruguay, Pardo, Tieté, and Parnahiba. For vessels drawing 16 feet it is navigable to Corrientes, upwards of 600 miles from its mouth.

PARAPET (Ital. *para-petto*, from *parare*, to protect, and *petto*, the breast), a wall raised higher than the gutter of a roof for protection; in

Ornamented Gothic Parapet.

military works, for defence against missiles from without (see FORTIFICATION); in domestic buildings, churches, &c., to prevent accident by falling from the roof. Parapets are of very ancient date. The Israelites were commanded to build 'a battlement' round their flat roofs. In classic architecture, balustrades were used as parapets. In Gothic architecture, parapets of all kinds are used. In

early work they are generally plain, but in later buildings they are pierced and ornamented with tracery, which is frequently of elaborate design, especially in French Flamboyant work. Shields and little arcades are also used as ornaments to parapets; and the battlements of castles are imitated in the parapets of religious and domestic buildings.

PARAPH (Gr. *para*, beside, and *hapto*, to touch), an addition to the signature formed by a flourish of the pen, which, during the middle ages, constituted some sort of provision against forgery. Its use is not altogether extinct in diplomacy, and in Spain the paraph is still a usual part of a signature.

PARAPHERNALIA (Gr. *para*, beside, or beyond; *phernē*, dower) is a term borrowed from the Roman law to denote certain articles of personal adornment and apparel belonging to a married woman. According to the usual rule in the law of England, all the personal property of a woman becomes the property of her husband when the marriage takes place, unless there is a marriage settlement; but there is an exception as regards the trinkets and dress of the wife so far as suitable to her rank in life, and which she continues to use during the marriage. In such a case the property in these articles does not vest absolutely in the husband. He cannot bequeath them by his will to a third person, but if he gave them to the wife, he may pawn, or sell, or give them away, and they can be seized in execution to pay his debts, except so far as they constitute necessary clothing. And if he were to die insolvent, they may, except that part which is necessary clothing, be taken by the husband's creditors. If the paraphernalia were given, not by the husband but by a third party before or during marriage, then they are presumed to be given for the wife's separate use, and the husband or his creditors cannot in any way interfere with them. In the law of Scotland, the paraphernalia of a married woman include not merely personal clothing and trinkets, but articles of furniture, such as a chest of drawers. The husband there can neither pawn, nor pledge, nor give away the paraphernalia, nor can his creditors attach them either during his life or after his death.

PARAPHRASE (Gr. *para*, beside, and *phrazein*, to speak) is the name given to a verbal expansion of the meaning either of a whole book, or of a separate passage in it. A paraphrase consequently differs from Metaphrase, or strictly literal translation, in this, that it aims to make the sense of the text clearer by a lucid circumlocution, without actually passing into commentary. The versified passages of Scripture, forming part of the Psalmody of the Scottish Church, are popularly known as 'the Paraphrases.'

PARAPLEGIA. See PARALYSIS.

PARĀS'ARA is the name of several celebrated personages of ancient India, met with in the *Mahābhārata* (q. v.), the *Purāṇas* (q. v.), and other works. Of one personage of this name, the *Mahābhārata* relates that he was the son of S'akti, who was the son of the patriarch Vasishthā. King Kalmishapāda once meeting with S'akti in a narrow path in a thicket, desired him to stand out of the way. The sage refused; on which the Rāja beat him with his whip, and S'akti cursed him to become a Rākshasa, or demon. The Rāja, in this transformation, killed and ate S'akti, together with the other sons of Vasishthā. S'akti, however, had left his wife, Adris'yanti, pregnant, and she gave birth to Parāś'ara, who was brought up by his grandfather. When he grew up, and was informed of his father's

death, he instituted a sacrifice for the destruction of all the Rākshasas, but was dissuaded from its completion by Vasishthā and other sages. The same legend is referred to by the *Viśhn'u-Purāṇa*, where P. is introduced as relating, himself, part of this story, and adding, that the saint Pulastya, one of the mind-born sons of Brahmā, in reward of the clemency he had shewn even towards such beings as the Rākshasas, bestowed on him the boon of becoming the author of a compendium, or rather the compiler, of the *Purāṇas*, and of the *Viśhn'u-Purāṇa* in particular. 'This tradition,' Professor Wilson observes (*Viśhn'u-Purāṇa*, ed. Hall, vol. i. p. 10), 'is incompatible with the general attribution of all the *Purāṇas* to Vyāsa; but it may perhaps point to a later recension when, to the native mind, Vyāsa would still remain the reputed author of the older *Purāṇas*, although, of course, even this assumption has little claim to historical truth.—A P., probably different from the one named, is the author of a celebrated code of laws; he is mentioned by Yājñavalkya in his standard work, and often quoted by the commentaries.—A probably third P. is the reputed author of a Tantra (q. v.); and a fourth, the author of an astronomical work.—Parāś'aras (in the plural) designates the whole family to which the different Parāś'aras belong.

PARASITE (Gr. from *para*, beside; *stos*, food; one who eats with another; hence one who eats at the expense of another), a common character in the Greek comedies; a low fellow, who is ready to submit to any indignity, that he may be permitted to partake of a banquet, and who lives as much as possible at the expense of others.

PARASITIC ANIMALS are numerous. Some of them are Entozoa, and some are Epizoa. See these heads. They belong to different classes, and even to different divisions of the animal kingdom; all, however, are invertebrate. Many are of the division *Articulata*, and many of the division *Radiata*. Besides worms of various kinds, there are among parasites not a few crustaceans, as the Lernæans, &c., and not a few insects, as the Louse. These insects constitute the order *Parasita* or *Anoplura*. The characters of the order are noticed in the article LOUSE. It remains, however, to be added, that the order is divided into two sections—in the first of which, *Pediculida*, the mouth is small and quite suctorial; whilst in the second, *Nirmidea*, it is furnished with mandibles and hooked maxillæ. The species of the first section are found only on man and mammals; those of the second section, almost exclusively on birds, although one infests the dog. The *Nirmidea* shew much greater activity than the *Pediculida*. When a bird dies, the bird-lice congregate near the beak, and seem disquieted, apparently anxious to change their abode. Some of the cirrhopods which live in the skin of large marine animals, as whales, can scarcely be regarded as parasitic animals, but rather bear to them a relation such as *Epiphytes* do to parasitical plants, not deriving their food from the animal on which they live. Tape-worms, ascarides, and other intestinal worms, do not directly draw sustenance from the animal in which they live, by extracting its juices, but they live at its expense, by consuming its food, after the food has undergone, in great part, the process of digestion.

PARASITIC DISEASES constitute one of the recognised orders of disease in Dr Farr's classification. See NOSOLOGY. In these diseases, certain morbid conditions are induced by the presence of animals or vegetables which have found a place of subsistence within some tissue or organ, or upon some surface of the body of man or of other animals.

Even plants are not exempt from disorders of this nature (see PARASITIC PLANTS). The forms of animal life giving rise to parasitic diseases are described in articles ASCARIDES, CESTOID-WORMS, ENTOZOA, EPIZOA, GUINEA-WORM, ITCH-INSECT, LOUSE, NEMATHELMIA, STRONGYLUS, TAPEWORMS, TRICHINA, &c. With the vegetable structures which give rise to special diseases we are less accurately acquainted, in consequence of the limited knowledge of cryptogamic botany possessed by many writers who have recorded their experience of these cases. These parasites are either *fungi* or *algae*, and are composed of simple sporules, germs, or cells, or of cells arranged in rows or groups, which are so minute as to require the microscope for their recognition. Fungi are the most numerous of all plants in regard to genera and species, and their growth is associated with serious injury both to animal and vegetable life. It is not, however, always easy to determine whether they are the direct cause of disease, or whether the diseased tissue has merely afforded a suitable nidus for their development. 'It is certain,' says Dr Aitken, who has entered more fully into this subject than any other English writer on the practice of medicine, 'that wherever the normal chemical processes of nutrition are impaired, and the incessant changes between solids and fluids slacken, then, if the part can furnish a proper soil, the cryptogamic parasites will appear. The soil they select is, for the most part, composed of epithelium or cuticle, acid mucus or exudation. Acidity, however, though favourable to their growth, is not indispensable, since some of the vegetable parasites grow upon alkaline or neutral ground, as on ulcerations of the trachea, or in fluid in the ventricles of the brain. Certain atmospheric conditions seem favourable to the occurrence of these vegetable parasites. For example, *Tinea tonsurans* may be quite absent for years in places such as workhouses, where it commonly exists, and then for several months every second or third child in the place gets the disease.

There is undoubted evidence from the observations and experiments of Devergie, Von Bürensprung, and others, that these parasitic diseases may be transmitted by contagion from horses, oxen, and other animals to man; while conversely, Dr Fox mentions an instance of a white cat which contracted the mange from *Tinea tonsurans* (ringworm of the scalp), which affected the children of the family to which it belonged—the fungus of the mange in the cat being the same fungus as that of *Tinea* in the human subject, viz., the *Tricophyton* (Gr. *tric* (tric-), of a hair, and *phyton*, a plant).

The principal vegetable parasites associated in man with special morbid states are arranged by Aitken (*The Science and Practice of Medicine*, 1863, 2d edit. vol. ii. p. 177) as follows: 1. The *Tricophyton tonsurans*, which is present in the three varieties of *Tinea tonsdens*—viz., *T. circinatus* (ringworm of the body), *T. tonsurans* (ringworm of the scalp), and *T. sycosis menti* (ringworm of the beard). 2. The *Tricophyton sporuloides*, which, together with the above, is present in the disease known as *Plica Polonica*. 3. The *Achorion Schönleini* and *Puccinia favi*, which are present in *T. favosa*, known also as *Favus* (q. v.), and *Porriigo scutulata* (the honeycomb ringworm). 4. The *Microsporon mentagrophyta*, which is present in *Mentagra*. 5. The *Microsporon furfur*, which occurs in *Pityriasis versicolor*. 6. The *Microsporon Audouini*, which is present in *Porriigo decalvans*. 7. The *Mycetoma* or *Chionyphe Carteri*, which gives rise to the disease known as the 'fungus foot of India,' &c. 8. The *Oidium albicans* of diphtheria and aphtha. 9. The *Cryptococcus Cerevisia*, or *Yeast Plant*, occurring in the urine and

contents of the stomach, if there is saccharine fermentation. 10. The *Sarcina Goodserii*, or *Mersipedia ventriculi* (of Robin), found in vomited matters and in the urine. There are strong grounds, based partly on botanical and partly on clinical observation, for believing that the various fungi already described are mere varieties of two or more species in various phases of development.

We shall conclude this article with a brief notice of the most dangerous of all the parasitic diseases—the *Fungus Foot* or *Fungous Disease of India*. It occurs in many parts of India, and the north-east shores of the Persian Gulf. It is a disease which occurs among natives only, so far as has been yet observed, and is undoubtedly due to the presence of a fungus which eats its way into the bones of the foot and the lower ends of the tibia and fibula, penetrating by numerous fistulous canals through the tissue of the entire foot, and tending to cause death by exhaustion, unless amputation is performed in due time. Dr Carter has described three forms of this disease, in which both the symptoms and the fungoid material differ considerably from each other. A few remarks on the first of these forms will suffice as an illustration of parasitic disease. In this form, the bones of the foot and the lower ends of the leg-bones are perforated in every direction with roundish cavities, varying in size from that of a pea to that of a pistol-bullet, the cavities being filled with the fungoid matter. The surrounding muscles, and subsequently the tendinous and fatty structures, are converted into a gelatiniform mass, in consequence of which the foot presents a peculiar turgid appearance. The structure of the globular fungoid masses is shewn in the accompanying figure, which was

drawn by Dr H. J. Carter from a specimen which he examined immediately after amputation. Examined under the microscope, the fungoid mass is found to consist of short, beaded, tawny threads or filaments, arising from a common centre, and having at their tips large spore-like cells.

Further notice of the parasitic diseases of the skin will be found in the articles *PITYRIASIS* (var. *versicolor*), *RINGWORM*, *SCALD-HEAD*, &c. The application of the Germ-Theory of disease would lead to the inclusion of many other diseases amongst parasitic disorders, in the wider sense of the word. Even specific fevers are by some so ranked. For diseases caused by the presence of the organisms known as bacteria, bacilli, &c. in the system, see *GERM-THEORY*, in SUPP. Vol. X.

PARASITIC PLANTS are plants which grow on other plants, and derive subsistence from their juices; the plants which live parasitically on animal tissues being generally called *Entophytes* (q. v.), although the distinction between these terms is not always preserved. *Epiphytes* (q. v.) differ

from parasitical plants in not subsisting on the juices of the plant which supports them, but merely on decayed portions of its bark, &c., or drawing all their nourishment from the air. Parasitical plants are numerous and very various; the greater number, however, and the most important, being small fungi, as Rust, Brand, Bunt, Smut, &c., the minute spores of which are supposed, in some cases, to circulate through the juices of the plants which they attack. Concerning some minute fungi, as the Mildews, it is doubted if they are truly parasitical, or if their attacks are not always preceded by some measure of decay. But among parasitic plants are not a few phanerogamous plants, some of which have green leaves; and some are even shrubby, as the Mistletoe, Loranthus, &c.; whilst the greater number have brown scales instead of leaves, as Dodder, Broom-rape, Lathraea, &c., and the whole of that remarkable order or class of plants called *Rhizanthæ* or *Rhizogens*, of which the genus *Rafflesia* is distinguished above all other plants for the magnitude of its flowers. Some parasitic plants, as the species of Dodder, begin their existence by independent growth from the ground; but when they have found suitable plants to take hold of and prey on, the connection with the ground ceases. Not a few, as Broom-rape and Lathraea, are root-parasites, generally attaching themselves to the roots of trees or shrubs; whilst some, as the Eyebright (*Euphrasia officinalis*), Yellow Rattle (*Rhinanthus crista galli*), Cow-wheat (*Melampyrum arvense*), &c., are parasitical only occasionally and partially, and are chiefly found on neglected grass lands. Root-parasites generally attach themselves by means of little tubercles, which bury themselves under the bark.

PARAY-LE-MONIAL, a town of Burgundy, department of Saône-et-Loire, celebrated for its Benedictine Abbey, founded in 973, which contains the tomb of Mary Margaret Alocque, the centre of recent pilgrimages by the confraternities of the Sacred Heart (q. v.). Pop. (1881) 3174; of commune, 3979.

PARBUCKLE is a mode of drawing up or lowering down an inclined plane any cylindrical object, as a barrel or a heavy gun, without the aid of a crane or tackle. It consists in passing a stout rope round a post or some suitable object at the top of the incline, and then doubling the ends under

Parbuckle.

and over the object to be moved. This converts the cask or gun into a pulley in its own behalf, and limits the pressure at each end of the rope to one-fourth the weight of the object moved, as felt on the incline. By hauling in the ends equally, the cask ascends, or *vice versa*.

PARCÆ (from the root *pars*, a part), the name given by the Romans to the goddesses of Fate or Destiny, who assigned to every one his 'part' or lot. The Greek name, *Moiræ*, has the same meaning (from *meros*, a share). They are only once

mentioned by Homer, who in every other instance speaks of Fate (*Moiræ*) in the singular, and whose Fate was not a deity but a mere personification, the destinies of men being made by him to depend upon the will of the gods; whilst, according to the later Greeks and the Romans, the gods themselves were subject to the control of the P. or *Moiræ*. Hesiod, however, who is almost contemporary with Homer, speaks of three Fates, whom he calls daughters of Night—Clotho, the spinner of the thread of life; Lachesis, who determines the lot of life; and Atropos, the inevitable. They were usually represented as young women of serious aspect; Clotho with a spindle, Lachesis pointing with a staff to the horoscope of man on a globe, and Atropos with a pair of scales, or sun-dial, or an instrument to cut the thread of life. In the oldest representations of them, however, they appear as matrons, with staves or sceptres. They had places consecrated to them throughout all Greece, at Corinth, Sparta, Thebes, Olympia, &c.

PARCELS, in the law of England, is the technical word for the article in a conveyance describing the lands, &c. conveyed.

PARCENER. See **COPARCENARY**.

PAROHIM, a town of the grand-duchy of Mecklenburg-Schwerin, stands on the Elde, which is here divided into two arms, 23 miles south-east of Schwerin. It is very old, is irregularly built, surrounded by beautiful gardens, and has a gymnasium and two churches. Pop. (1880) 9063, employed in agriculture, in the manufacture of tobacco, cloth, leather, and brandy, and in weaving.

PARCHMENT, one of the oldest inventions of writing materials, was known at least as early as 500 years B.C. Herodotus speaks of books written upon skins in his time. Pliny, without good grounds, places the invention as late as 196 B.C., stating that it was made at Pergamos (hence the name *Pergamena*, corrupted into Eng. parchment) in the reign of Eumenius II., in consequence of Ptolemy of Egypt having prohibited the exportation of papyrus. Possibly the Pergamian invention was an improvement in the preparation of skins which had certainly been used centuries before. The manufacture rose to great importance in Rome about a century B.C., and soon became the chief material for writing on; and its use spread all over Europe, and retained its pre-eminence until the invention of paper from rags, which from its great durability proved a fortunate circumstance for literature.

There are several kinds of parchment, prepared from the skins of different animals, according to their intended uses. The ordinary writing parchment is made from those of the sheep and of the she-goat; the finer kind, known as *vellum*, is made from those of very young calves, kids, and lambs; the thick common kinds, for drums, tambourines, battle-dores, &c., from those of old he-goats and she-goats, and in Northern Europe from wolves; and a peculiar kind is made from asses' skins, the surface of which is enamelled. It is used for tablets, as blacklead writing can be readily removed from it by moisture. The method of making parchment is at first the same as in dressing skins for leather. The skins are limed in the lime-pit until the hair is easily removed. They are then stretched tightly and equally, and the flesh side is dressed as in currying, until a perfectly smooth surface is obtained. It is next *ground* by rubbing over it a flat piece of pumice-stone, previously dressing the flesh side only with powdered chalk, and slaked lime sprinkled over it. It is next allowed to dry, still tightly stretched on the frame. The drying process is an

important one, and must be rather slowly carried on, for which purpose it must be in the shade. Sometimes these operations have to be repeated several times, in order to insure an excellent quality, and much depends upon the skill with which the pumice-stone is used, and also upon the fineness of the pumice itself. When quite dried, the lime and chalk are removed by rubbing with a soft lamb-skin with the wool on.

PARCHMENT, VEGETABLE. This remarkable substance was made known by Mr W. E. Gaine in 1854, and again by the Rev. J. Barlow in 1857. It resembles animal parchment so closely, that it is not easy to distinguish the difference. It is made from the water-leaf, or unsized paper, by immersing it only for a few seconds in a bath of oil of vitriol, diluted with one-half its volume of water. The exactness of this dilution is of the greatest importance to the success of the results. The dilute acid must not be used immediately after mixing, but must be suffered to cool to the ordinary temperature; without attention to these apparently trifling points, the operator will not succeed.

The alteration which takes place in the paper is of a very remarkable kind. No chemical change is effected, nor is the weight increased; but it appears that a molecular change takes place, and the material is placed in a transition state between the cellulose of woody fibre and dextrin. Vegetable parchment is in some respects preferable to the old kind, for insects attack it less, and it can be made so thin as to be used for tracing paper, and bears wet without injury. Messrs De la Rue have the credit of giving practical effect to the invention.

PARDUBITZ, a town of Austria, in Bohemia, 61 m. E. of Prague. It has copper, iron, and paper manufactures. P. was the headquarters of the king of Prussia, 7th June 1866. Pop. (1880) 10,010.

PARÉ, AMBROISE, a renowned French surgeon, and the father of modern surgery, was born about the beginning of the 16th c., at Laval, department of Mayenne, France. His father, who was a trunk-maker, was unable to afford him a literary education, and apprenticed him to a barber and surgeon. P., after a brief term of service, acquired such a fondness for surgery and anatomy, that, abandoning his master, he went to Paris to prosecute his studies. His means for doing so were very limited; he could afford to obtain instruction from only the more obscure teachers; few books were within his reach, yet by dint of perseverance and the exercise of a rare discrimination, combined with the valuable practice in the Hôtel de Dieu of Paris, he laid a solid foundation for future eminence. In 1536, P. was received as a master barber-surgeon, and joined in this capacity the army of Marshal René de Monte-Jean, which was on the point of starting for Italy. During this campaign he improved the mode of treatment of gun-shot wounds, which had up to this time been of the most barbarous kind—namely, cauterisation with boiling oil. His reputation as well as his skill were greatly heightened during this campaign, and as he himself says: 'If four persons were seriously wounded I had always to attend three of them; and if it were a case of broken arm or leg, fractured skull, or fracture with dislocation, I was invariably summoned.' In 1539, he returned to Paris, whither his high renown had preceded him, and was received with distinction by the Royal College of Chirurgery, of which he was subsequently appointed president. On the war being renewed, he was again attached to the army, under the Vicomte de Rohan, afterwards under Antoine de Bourbon, Duke of Vendôme. It was during this

campaign that he cured François, the second Duke of Guise, of the wound which conferred upon him the sobriquet of *Balafré*, and that he substituted ligature of the arteries for cauterisation with a red-hot iron after amputation. The idea of this mode of repressing hemorrhage had long been in existence, but he was the first to show that it could safely be applied to practice. Many other important improvements in surgery were introduced by him at this time. In September 1552 he was appointed surgeon to King Henry II., and in the following year was taken prisoner at Hedin; he was however released, in consideration of his having cured Colonel de Vandeville, after rejecting the brilliant offers made him by the Duke of Savoy to remain in his service. Returning to Paris, honours were showered upon him; and though he was ignorant of Latin, the *conditio sine qua non* of a liberal education at that time, no hesitation was shewn in conferring upon him learned titles and degrees. He attended Francis II. on his death-bed, and continued to hold the office of king's surgeon to his successors, Charles IX. and Henry III. The former of these monarchs, whose life had been gravely threatened by an injury inflicted by his physician Portail, and who had been preserved by P., testified for him the greatest esteem, and saved him during the massacre of St Bartholomew by locking him up in his own chamber. During the latter part of P.'s life, he was much employed in the publication of his various writings, and suffered considerable annoyance from the envious spirit displayed towards him by his professional brethren, who showered obloquy upon him for having, as they said, 'dishonoured science by writing in the vulgar tongue.' P. died at Paris, December 22, 1590. His writings have exercised a great influence on the practice of surgery in all countries to which they have penetrated, and are held of the highest authority on the subject of gun-shot wounds. The first complete edition of them appeared at Lyon in 1562, and the last, edited by M. Malgaigne, at Paris (1840—1841, 3 vols.). Besides these are 8 Latin editions, and more than 15 translations into English, Dutch, German, &c. As an instance of his great popularity in the army, it may be mentioned that the soldiers of the garrison of Metz, of their own accord, gave him a triumphal reception on his entering that town.

PAREGORIC, or PAREGORIC ELIXIR (from the Gr. *paregoricos*, soothing), the *Compound Tincture of Camphor* of the London, and the *Camphorated Tincture of Opium* of the British Pharmacopœia, consists of an alcoholic solution of opium, benzoic acid, camphor, and oil of anise, every fluid ounce containing two grains each of opium and benzoic acid, and a grain and a half of camphor. This preparation is much used both by the profession and the public. In doses of from one to three drachms, it is an excellent remedy for the chronic winter-cough of old people, the opium diminishing the bronchial secretion and the sensibility of the pulmonary mucous membrane, while the benzoic acid and oil of anise act as stimulating expectorants. It has also been found useful in chronic rheumatism.

PAREIRA-BRAVA. See CISMAMPELOS.

PARELLA (Fr. *parelle* or *perelle*), a name often given to some of those crustaceous lichens which are used to produce Archil, Cudbear, and Litmus; but which more strictly belongs to one species, *Lecanora parella*, resembling the Cudbear Lichen, but with somewhat plaited warty crust, and shields (*apothecia*) having a concave disk of the same colour as the thick tumid even border. Like the Cudbear

Lichen—to which it is far superior in the quality of the dye-stuff obtained from it—it grows on rocks in mountainous districts both in Britain and on the continent of Europe, being particularly abundant in Auvergne and other parts of France.

PARENCHYMA. See **CELLULAR TISSUE**.

PARENT AND CHILD. The legal relation between parent and child is one of the incidents or consequences of the relation of husband and wife, and flows out of the contract of marriage. The legal is to be distinguished from the natural relation, for two persons may be by the law of nature parent and child, while they are not legally or legitimately so. Hence a radical distinction exists between natural or illegitimate and legitimate children, and their legal rights as against their parents respectively are very different. Legitimate children are the children of two parents who are recognised as married according to the laws of the country in which they are domiciled at the time of the birth; and according to the law of England, if a child is illegitimate at the time of the birth, nothing that can happen afterwards will ever make it legitimate, the maxim being 'once illegitimate always illegitimate'—a maxim which, as will be stated, has some exceptions in Scotland. In treating of the laws affecting the mutual relation of parent and child, the laws of England and Ireland, which differ from the law of Scotland in material respects, will first be stated.

1. *As to Legitimate Children.*—These laws relate first to the liability of the parent to maintain the child, and the rights of the child in the event of the parent's death. As regards the maintenance of the child, it is somewhat singular that, according to the law of England, there is no duty whatever on the parent to support the child, and consequently no mode of enforcing such maintenance. The law of nature was probably considered sufficient to supply the motives which urge a parent to support the child, but the municipal law of England has not made this duty compulsory. This defect was to some extent remedied when what is called the Poor-Law was created by statute in the reign of Elizabeth, by which law parents and children are compellable to a certain small extent, but only when having the pecuniary means to do so, to support each other, or rather to help the parish authorities to do so. But apart from the Poor-Law statutes, there is no legal obligation on the parent to support the child, nor on the child to support the parent. Hence it follows, that if the child is found in a destitute state, and is taken up, fed, clothed, and saved from starvation by a stranger, such stranger cannot sue the parent for the expense, or any part of it, however necessary to the child's existence. In order to make the father liable for maintenance, there must in all cases be made out against him some contract, express or implied, by which he undertook to pay for such expense; in other words, the mere relationship between the parent and child is not of itself a ground of liability. But when the child is living in the father's house, it is always held by a jury or court that slight evidence is sufficient of, at least, an implied promise by the father to pay for such expenses. As, for example, if the child orders clothes or provisions, and the father sees these in use or in process of consumption, it will be taken that he assented to and adopted the contract, and so will be bound to pay for them. So if a parent put a child to a boarding-school, very slight evidence of a contract will be held sufficient to fix him with liability. Nevertheless, in strictness of law, it is as necessary to prove a contract or agreement on the part of the parent to pay for these expenses as it is

to fix him with liability in respect of any other matter. When it is said that a parent is not compellable by the common law to maintain his child, it must, at the same time, be observed that if a child is put under the care and dominion of an adult person, and the latter wilfully neglect or refuse to feed or maintain such child, whereby the child dies or is injured, such adult will incur the penalties of misdemeanour; but this offence does not result from the relationship of parent and child, and may arise between an adult and child in any circumstances, as where a child is an apprentice or servant. The change as to the liability of parents to maintain their children created by the Poor-Laws amounts merely to this, that if a person is chargeable to the parish, that is, not able to work as well as destitute, and if the overseers or guardians are bound to support him or her, then the parish authorities may reimburse themselves this outlay, or part of it, by obtaining from justices of the peace an order commanding the parent or child of such pauper to pay a certain sum per week towards the relief. This is, however, only competent when the relative is able to pay such sum, and in all cases the sum is of necessity very small. Not only parents, but grand-parents, are liable under the Poor-Law Act to the extent mentioned. Another provision in the Poor-Law and other kindred acts is, that if a parent runs away and deserts his children, leaving them destitute and a burden on the parish, the overseers are entitled to seize and sell his goods, if any, for the benefit and maintenance of such children; and if the parent, so deserting the children, is able by work or other means to support them, such parent may be committed to prison as a rogue and vagabond. Not only, therefore, is a parent during life not bound to maintain his or her child (with the above exceptions), but also after the parent's death the executors or other representatives of the parent, though in possession of funds, are not bound. It is true that if the parent die intestate, both the real and personal property will go to the children; but the parent is entitled, if he choose, to disinherit the children, and give away all his property to strangers, provided he execute his will in due form, which he may competently do on death-bed if in possession of his faculties.

Another important point of law, affecting the mutual relation of parent and child, is the right of the parent to the custody of the child. At common law it is the father who has the right to the custody of the child until majority at least, as against third parties, and no court will deprive him of such custody except on strong grounds. Whenever the child is entitled to property, the Court of Chancery so far controls his parental right, that if the father is shewn to act with cruelty, or to be guilty of immorality, a guardian will be appointed. A court of common law also has often to decide in cases of children brought before it by *habeas corpus*, when parties have had the custody against the father's will. In such cases, if the child is under fourteen, called the age of nurture, and the father is not shewn to be cruel or immoral, the court will order the child to be delivered up to him; but if the child is above fourteen, or, as some say, above sixteen, the court will allow the child to choose where to go. So the father is entitled by his will to appoint a guardian to his children while they are under age. The mother had, at common law, no right as against the father to the custody of the children, however young; but under a statute of 36 and 37 Vict. c. 12, she is entitled to the custody of the child while under sixteen years of age, or rather she is entitled to apply to the Court of Chancery for leave to keep the children while under that age, provided she is

unobjectionable in point of character; and access may be allowed to the father or guardian. If the parents separate by agreement, no stipulation will be enforced which is prejudicial to the child. In case of divorce or judicial separation, the Court of Divorce has power to direct who is to have the custody of the children.

2. Illegitimate Children.—It has been already stated that, at common law, the parent of a legitimate child is not bound to maintain it, and this is equally true of an illegitimate child—i. e., a child born not in wedlock. In strictness of law, an illegitimate child has no father, which means practically that in case of the death of the father without making a will, the law will not treat such child as entitled to the ordinary legal rights of a legitimate child—i. e., to a share of the father's property. The child is not legally related to the father in this sense. With regard to the mother, she also is not bound to maintain her child according to the common law; but the Poor-Law Acts have made an important qualification of her rights and duties. As between the father and mother of the child, the law is this: The father is not bound even by the Poor-Laws to maintain the child, and the parish officers cannot now institute any proceeding whatever against him for this purpose; but the mother can, to a certain extent, enforce against him a contribution towards the child's maintenance and education, or the guardians may do so. It is entirely discretionary on the mother to take any proceeding against the father, but if she chooses she can do so; and the first step is to go before a justice of the peace, and obtain a summons of affiliation. The father is thus cited before the magistrate, and if the mother swears that he is the father of the child, and is corroborated in some material part of this statement by a third party, the magistrate may make an order against the father to pay the expenses of lying-in, and a weekly sum not exceeding five shillings till the child attains the age of sixteen. The mother may make this application either a few months before the birth, or within twelve months after the birth; and even after that time, provided she can prove that the putative father paid her some money on account of the child within such twelve months. The putative father, in these cases, is a competent and compellable witness. The utmost, therefore, that the father can be made to contribute towards the child's maintenance is only a portion of the whole, the chief burden being thrown on the mother, who is assumed to be the more blameable party. Though she is not bound by the common law to maintain her child, yet the Poor-Laws make her liable to maintain the child till it attains sixteen; and not only is she bound, but any man who marries her is also by statute bound to support all her illegitimate (and also legitimate) children till they attain sixteen. The result is, that illegitimate children under sixteen are better provided for by the present state of the law than legitimate children, inasmuch as the mother is positively bound to support her illegitimate child, and only to a less extent her legitimate child. As regards the custody of illegitimate children, the mother is the party exclusively entitled, for the father is not deemed, in point of law, to be related to such child. Yet if the father has, in point of fact, obtained the custody of such child, and the child is taken away by fraud, the courts will restore the child to his custody, so as to put him in the same position as before. Though illegitimate children will not succeed to the father's property in the event of his dying without a will, there is nothing to prevent him making his will in their favour, provided he expressly name and identify

them, and not leave it to them by the description of 'his children,' which in point of law they are not.

Scotland.—The law of parent and child in Scotland differs materially from the law of England and Ireland. In Scotland, a child may be born a bastard, and yet if the parents afterwards marry, this will legitimise the child, and give the child the right to succeed to the father's property. A difficulty sometimes arises where, before the father and mother of a bastard marry, the father has had a legitimate family by another woman, in which case it is held that the bastard, though oldest in point of age, does not take precedence of the legitimate children. The law of Scotland also differs from that of England as regards the obligation of parent and child to maintain each other. There is a legal obligation on both parties to maintain each other if able to do so, and either may sue the other for aliment at common law; but this obligation extends only to what may be called subsistence money, and does not vary according to the rank of the party. Thus an earl is bound to pay no more for the aliment of his son than any other father. As regards all maintenance beyond mere subsistence, the law does not materially differ from that of England, and a contract must be proved against the father before he can be held liable to pay. The legal liability as between parent and child is qualified in this way by the common law, that if a person has both a father and a child living and able to support him, then the child is primarily liable, and next the grandchild, after whom comes the father, and next the grandfather. Not only are parent and child liable to support each other while the party supporting is alive, but if he die, his executors are also liable; and this liability is not limited by the age of majority, but continues during the life of the party supported. Such being the common law of Scotland, it was scarcely necessary, as in England, for the Poor-Law to supply any defect; but the Scotch Poor-Law supplements the common law, by imposing a penalty on a father or mother (though not *vice versa*) who neglects to support a child. Another advantage which a Scotch child has over an English child is, that the father cannot disinherit it—at least so far as concerns his movable property; and even in case of heritable property, the rights of the child were so protected, that unless the father made away with his heritable property sixty days before his death, or while in sound health, it was too late to prejudice his heir-at-law; this rule was, however, abolished in 1870 by 34 and 35 Vict. c. 81. This was called the Law of Death-bed (q. v.); but as regards the father's movable property, he cannot by any will he can make at any time of his life deprive the children of one-third, or, if their mother is dead, of one-half of such property. This is called the children's right to Legitim (q. v.), a right which they can vindicate, whatever may be their age when the father dies. With regard to the custody of children in Scotland, the rule is, that the father is entitled to the custody as between him and the mother; but the Court of Session has power to regulate the custody in case the children are entitled to property, and the father is of an immoral or cruel character; and the court will also interfere to allow to the mother access to the children at certain times and seasons. Another important difference between a Scotch and English child is this, that whereas in England the father or guardian, or the Court of Chancery, has power to control the custody of the person of the child to a certain extent, until the child attains the age of 21, in Scotland such power entirely ceases when the child attains the age of 14 or 12, according as

such child is male or female. At the age of 14, a boy, and at 12, a girl, in Scotland, is entire master or mistress of his or her movements, and can live where he or she pleases, regardless of any parent or court. They can marry at that age at their own uncontrolled discretion, and act in all respects with the same freedom as adults. As regards the disposition of their property there are some restrictions, but as regards the disposal of their persons there are none, after the ages of 14 and 12 respectively.

2. *Illegitimate Children.*—The law of Scotland as to illegitimate children also differs in some respects from that of England. Both the father and mother of a bastard are bound by law to support such child, and the obligation transmits to the personal representatives of the father or mother. Moreover, by the Poor-Law statute both are liable to a penalty for neglecting to support the child. The mother of illegitimate children is entitled to their custody till the age of ten, if daughters, and if sons, till the age of seven; but the limit is not clearly defined. If the father support the child after the above age, he is entitled to the custody. The mother does not apply to a magistrate for a summons of affiliation in order to fix the paternity; but she may bring an action of filiation and aliment, in which the question of paternity is settled. The father may be judicially examined, and is a competent witness; and it is usual for the court to decree an aliment, varying from £4 per annum against labourers, up to £10 against persons in better circumstances. In Scotland, as in England, the father of a bastard child is not deemed related, in point of law, to such child; and if he desires to provide for such child, it must be done by deed or will, in which the child is identified, and not merely described under the general designation of 'child,' which he is not.

PARENTHESIS, a term originally Greek, and signifying *insertion* or *intercalation*, is in composition a clause, or part of a sentence or argument, not absolutely essential to the sense, but generally serving either for explanation or confirmation, sometimes chiefly for rhetorical effect. A parenthesis is usually included between the marks (), instead of which the *dash* (—) at the beginning and end of the parenthesis is frequently but improperly employed.

PARHELION. See HALOS.

PARIAH DOG. See CUR.

PARIAN CHRONICLE. See ARUNDEL MARBLES.

PARIAS is the name given to the lowest class of the population of India—to that class which, not belonging to any of the castes of the Brahminical system, is shunned even by the lowest Hindu professing the Brahminical religion, as touching a Paria would render him impure. The P. seem to belong to a negro race, as appears from their short woolly hair, flat nose, and thick lips; they are, besides, of short stature, and their propensities are of the coarsest kind. Despised by the Hindus, and ill used by the conquerors of India, they have, in some parts of India, gradually sunk so low that, to judge from the description which is given of their mode of living by different writers, it is scarcely possible to imagine a more degraded position than that which is occupied by these miserable beings.

PARIDÆ and PARUS. See TIT.

PARING AND BURNING consists in cutting off the surface of the soil in thin slices, which are then dried and burned. This is the most effectual way of reclaiming peat and other waste land, the surface of which is matted with coarse plants, difficult of decay. It is also applied advantageously

to cold clay soils, apt to produce rank weeds and coarse grasses, which are to be broken up after lying for some time in grass. The ashes of the plants, consisting of potash and other salts, act as a powerful manure; while the clay being reduced to the state of brick-dust, both improves the texture of the soil, and acts as an absorbent for retaining moisture and nutritive gases, and giving them out to the roots of growing plants. On thin light soils the operation is rarely advisable, for much of the scanty volatile vegetable matter is dissipated; however if care is taken to make the turfs merely smoulder without flame, so that the plants are rather charred than burned, it is doubtful whether more dissipation takes place than if the plants were ploughed down, and allowed slowly to decay. The plot to be reclaimed should, if necessary, be dried by stone or tile drains; and all large stones grubbed up, and carted or conveyed off upon sledges. The paring is to be done, if possible, in the months of April and May, in order to have the most favourable part of the year for drying the parings well before burning. There are ploughs specially made for paring, with a very flat share; but the best method is to employ the *breast-plough* or *paring-spade*, as the surface is in most cases very irregular, and it is desirable to have the slices very thin. The parings should be burned directly they are sufficiently dry, as, after lying a month or six weeks, they begin to unite with the ground, and imbibe moisture from the young grass vegetating beneath them. Sometimes they can be burned as they lie, without being collected into heaps; and in this way, the fire, in consuming the liny side, which is undermost, chars the surface of the soil at the same time. If burned in heaps, the heaps should be very small, in order to secure a good black ash, instead of the hard lumps of red ash produced by large fires. The weeds or refuse organic matters are thus only charred, instead of being entirely burned away; whilst the mineral matters are left in a soluble state instead of being reduced, as is too apt to be the case where the operation is carelessly conducted, into an insoluble semi-vitrified slag. To attain these desirable results a smouldering fire must be maintained, by keeping the outside layer of sods so close as to prevent the fire from kindling into flame. The ashes should be spread, care being taken to clear the bottoms of the heaps well out, so that the first crop may be free from patches. The cost of thus paring, burning, and spreading is about £1 per acre.

PARIS, a genus of plants of the small endogenous or dictyogenous natural order *Trilliaceae*, of which one species, *P. quadrifolia*, called HERB PARIS, is not uncommon in moist shady woods in some parts of Britain. It is rarely more than a foot high, with one whorl of generally four leaves, and a solitary flower on the top of the stem, followed by a berry. The berry is reputed narcotic and poisonous, but its juice has been employed to cure inflammation of the eyes. The root has been used as an emetic.

PARIS, also called ALEXANDER, was, according to Homer, the second son of Priam and Hecabe, sovereigns of Troy. His mother dreamed during her pregnancy that she gave birth to a firebrand, which set the whole city on fire, a dream interpreted by Æscus or Cassandra to signify that P. should originate a war which should end in the destruction of his native city. To prevent its realisation, Priam caused the infant to be exposed upon Mount Ida by a shepherd named Agelaus, who found him, five days after, alive and well, a she-bear having given him suck. Agelaus brought him up as his own son, and he became a shepherd on Mount Ida,

distinguishing himself by his valour in protecting the other shepherds from their enemies—whence his name, Alexander, 'the defender of men.' An accident having revealed his parentage, old Priam became reconciled to his son, who married Eione, daughter of the river-god Cebren. But his mother's dream was to come true for all that. He was appealed to, as umpire, in a strife which had arisen among the three goddesses, Hera (Juno), Athene (Minerva), and Aphrodite (Venus), as to which of them was the most beautiful, the goddess Eris (Strife) having revengefully flung among them, at a feast to which she had not been invited, a golden apple (of discord) inscribed *To the Most Beautiful*. Each of the three endeavoured to bribe him. Hera promised him dominion over Asia and wealth; Athene, military renown and wisdom; Aphrodite, the fairest of women for his wife—to wit, Helene, the wife of the Lacedæmonian king, Menelaus. P. decided in favour of Aphrodite, hence the animosity which the other two goddesses displayed against the Trojans in the war that followed. P. now proceeded to seek Helene, whom he carried away from Lacedæmon in her husband's absence. 'The rape of Helen' is the legendary cause of the Trojan war, on account of which P. incurred the hatred of his countrymen. He deceitfully slew Achilles in the temple of Apollo. He was himself wounded by a poisoned arrow, and went to Mount Ida to be cured by Eione, who possessed great powers of healing; but she avenged herself for his unfaithfulness to her by refusing to assist him, and he returned to Troy, and died. He was often represented in ancient works of art generally as a beardless youth, of somewhat effeminate beauty.

PARIS (the ancient *Lutetia Parisiorum*), the metropolis of France, is situated in 48° 50' N. lat., and 2° 20' E. long., on the Seine, about 110 miles from its mouth. Pop. (1869) 1,875,000; (1872) 1,799,250; (1876) 1,988,806; and at end of 1881, 2,269,023. Its circumference is upwards of 25 miles. It lies in a hollow about 200 feet above the level of the sea, and is surrounded by low hills, which in their highest ranges to the north only attain an elevation of 290 or 300 feet, as at Montmartre and Belleville. These hills, which are separated by narrow valleys or plateaux, as those of St Denis to the north, Ivry to the east, Montrouge to the south, and Grenelle to the south-west, are encircled at a distance of from two to five miles by an outer range of heights, including Villejuif, Meudon, St Cloud, and Mont-Valérien, the highest point in the immediate vicinity of the city. The Seine, which enters P. in the south-east at Bercy, and leaves it at Passy in the west, divides the city into two parts, and forms the two islands of La Cité and St Louis, which are both covered with buildings.

The earliest notice of P. occurs in Julius Cæsar's *Commentaries*, in which it is described under the name of *Lutetia*, as a collection of mud huts, composing the chief settlement of the Parisii, a Gallic tribe, conquered by the Romans. The ruins of the *Palatium Thermarum* (Palais des Thermes), and of ancient altars, aqueducts, and other buildings, shew that even in Roman times the town extended to both banks of the Seine. *Lutetia* began in the 4th c. to be known as *Parisia*, or P., from the Celtic tribe of the Parisii, to whom it belonged. In the 6th c., P. was chosen by Clovis as the seat of government; and after having fallen into decay under the Carlovingian kings, in whose time it suffered severely from frequent invasions of the Northmen, it finally became in the 10th c. the residence of Hugh Capet, the founder of the Capetian dynasty, and the capital of the Frankish monarchy.

From this period, P. continued rapidly to increase, and in two centuries it had doubled in size and population. In the middle ages, P. was divided into three distinct parts—La Cité, on the islands; the Ville, on the right bank; and the Quartier Latin, or University, on the left bank of the river. Louis XI. did much to enlarge P., and to efface the disastrous results of its hostile occupation by the English during the wars under Henry V. and Henry VI. of England; but its progress was again checked during the wars of the last of the Valois, when the city had to sustain several sieges. On the accession of Henri IV. of Navarre, in 1589, a new era was opened to Paris. The improvements commenced under his reign were continued under the minority of his son, Louis XIII. Louis XIV. converted the old ramparts into public walks or *boulevards*, organised a regular system of police, established drainage and sewerage works, founded hospitals, alms-houses, public schools, scientific societies, and a library, and thus gave to P. a claim to be regarded as the focus of European civilisation. The terrible days of the Revolution caused a temporary reaction. The improvement of P. was recommenced on a new and grander scale under the first Napoleon, when new quays, bridges, markets, streets, squares, and public gardens were created. All the treasures of art and science which conquest placed in his power were applied to the embellishment of P., in the restoration of which he spent more than £4,000,000 sterling in twelve years. His downfall again arrested progress, and in many respects P. fell behind other European cities.

Renovation of various sorts was recommenced under Louis-Philippe; but as lately as 1834, much of the old style of things remained; the gutters ran down the middle of the streets, there was little underground drainage from the houses, oil-lamps were suspended on cords over the middle of the thoroughfares, and, except in one or two streets, there were no side-pavements. It was reserved for Napoleon III. to render P. the most commodious, splendid, and beautiful of modern cities. When he commenced his improvements, P. still consisted, in the main, of a labyrinth of narrow, dark, and ill-ventilated streets. He resolved to pierce broad and straight thoroughfares through the midst of these, to preserve and connect all the finest existing squares and boulevards; and in lieu of the old houses pulled down in the heart of the town, to construct, in a ring outside of it, a new city in the most approved style of modern architecture. With the assistance of Baron Haussman, the Prefect of the Seine, his schemes were carried out with rare energy and good taste. Two straight and wide thoroughfares, parallel to and near each other, crossed the whole width of Paris from north to south through the Cité; a still greater thoroughfare was made to run the whole length of the town, north of the Seine, from east to west. The old boulevards were completed so as to form outer and inner circles of spacious streets—the former chiefly lying along the outskirts of the old city, the latter passing through and connecting a long line of distant suburbs. In the year 1867, when the international exhibition was opened, P. had become in all respects the most splendid city in Europe; and in that year it was visited by upwards of a million and a half of foreigners. Many further improvements were then contemplated. New botanical and zoological gardens were to be formed; the museums and class-rooms of the *Jardin des Plantes* were to be rebuilt; an underground railway was to be formed, crossing P. from east to west; Montmartre was to be levelled, and the Seine was to be deepened up to Grenelle, the point where it

leaves the town; and there a harbour was to be formed for sea-going ships, which was to convert P. into a *port de mer*. Financial and political difficulties were, however, at hand (see FRANCE), and these great schemes had to be postponed. The siege of P. by the Germans, which lasted from 19th September 1870 to 28th January 1871, caused much less injury to the city than might have been expected—it was reserved for a section of the Parisian population to commit an act of Vandalism without a parallel in modern times. On the 18th of March, the Red Republicans, who had risen against the government, took possession of Paris. On the 27th March, the Commune was declared the only lawful government. Acts of pillage and wanton destruction followed. On the 15th of May, the column erected to the memory of Napoleon and the Great Army, in the Place Vendôme, one of the principal squares of P., was solemnly pulled down as 'a monument of tyranny.' The government troops under Marshal MacMahon attacked the insurgents, and kept them from doing further mischief. The former succeeded in entering Paris on the 20th of May, and next day the Communists began systematically to set fire with petroleum to a great number of the chief buildings of P., public and private. The fire for a time threatened to destroy the whole city. It raged with the greatest fury on the 24th, and was not checked until property had been lost to the value of many millions sterling, and historical monuments were destroyed which never can be replaced. The horror inspired by the Commune for a time drove the wealthy classes from Paris, and it was feared that it would lose its prestige as a European capital. This, however, has not proved to be the case. In the autumn of 1873, all the private houses burnt had been rebuilt—the monuments only partially injured had been restored, and the streets and public places were as splendid and gay as in the best days of the Empire. There remained, however, to recall the Commune, the blackened ruins of the Tuileries, the Hôtel de Ville, and two or three other buildings to which we are about to refer.

The Seine, in passing through P., is spanned by 28 bridges. The most celebrated and ancient are the Pont Notre-Dame, erected in 1500, and the Pont-Neuf, begun in 1578, completed by Henri IV. in 1604, and thoroughly renovated in 1852. This bridge, which crosses the Seine at the north of the Ile-de-la-Cité, is built on 12 arches, and abuts near the middle on a small peninsula, jutting out into the river, and planted with trees, which form a background to the statue of Henri IV. on horseback, which stands in the central open space on the bridge. Among the other bridges, the handsomest are the Pont de la Concorde, 160 yards long, built in 1787—1790; the Pont du Carrousel, Pont d'Austerlitz, and the Pont d'Jéna, both of the time of the First Empire; and the Pont des Invalides, Pont de l'Alma, and Pont de Solférino—all handsome structures, adorned with military and naval trophies, commemorative of events and victories connected with the Second Empire. These bridges all communicate directly with the spacious quays, planted with trees, which line both banks of the Seine, and which, together with the Boulevards, give special characteristic beauty to the city. Although the most ancient quays—as those des Augustins and de la Mégisserie—date from the 14th c., the greater part of these magnificent embankments, measuring 12 miles in extent, is due to the first Napoleon and the late emperor.

Before speaking in detail of the streets, boulevards, and places or squares of P., it is proper to mention that the private houses as well as the

public buildings are built of a light-coloured kind of limestone, easily wrought and carved ornamentally. With this material, they are reared in huge blocks, rising to a height of six or seven stories; each floor constituting a distinct dwelling; access to all the floors in a tenement being gained by a common stair, which is usually placed under the charge of a porter at the entrance. Very frequently, the tenements surround an open quadrangle, to which there is a spacious entry, the gate of which is kept by a porter for the whole inhabitants of the several stairs. In these respects, therefore, P. differs entirely from London; for instead of extending rows of small brick buildings of a temporary kind over vast spaces, the plan consists of piling durable houses on the top of each other, and confining the population to a comparatively limited area. In the great new streets which were formed in the time of the late emperor, this general plan has been adhered to, but with this difference, that instead of being narrow and crooked, they are wide and straight. Among the finest of them are the Rue de Rivoli, two miles in length, the Rue de la Paix, the Rue du Faubourg St Honoré, and the Rue Royale. The Boulevards, which extend in a semicircular line on the right side of the Seine, between the nucleus of the city and its surrounding quarters, present the most striking feature of Paris life. In all the better parts of the city they are lined with trees, seats, and little towers called *Veepasciennes*, covered with advertisements. Restaurants, cafés, shops, and various places of amusement succeed one another for miles, their character varying from the height of luxury and elegance in the western Boulevard des Italiens, to the homely simplicity of the eastern Boulevards Beaumarchais and St Denis. Among the public squares or *places*, the most noteworthy is the Place de la Concorde, which connects the Gardens of the Tuileries with the Champs-Élysées, and embraces a magnificent view of some of the finest buildings and gardens of Paris. In the centre is the famous obelisk of Luxor, covered over its entire height of 73 feet with hieroglyphics. It was brought from Egypt to France, and in 1836 placed where it now stands. On the site of this obelisk stood the revolutionary guillotine, at which perished Louis XVI., Marie Antoinette, Philippe Egalité, Danton, Robespierre, and a host of other victims. Of the other squares, the following are some of the most handsome: the Place du Carrousel, between the Tuileries and Louvre; the Place Vendôme, already referred to, with Napoleon's Column of Victory; the Place de la Bastille, where once stood that famous prison and fortress; the Place Royale, with its two fountains and a statue of Louis XIII.; the Place de l'Hôtel de Ville, formerly Place de la Grève, for many ages the scene of public executions, and the spot at which some of the bloodiest deeds of the Revolution were perpetrated. The Porte St Martin and Porte St Denis, which were erected by Louis XIV. to commemorate his victories in the Low Countries, and are adorned with bas-reliefs representing events of these campaigns, mark the ancient limits of the most turbulent quarters of the Paris of the past; while the Arc de l'Étoile, begun by Napoleon in 1806, and completed in 1836 at a cost of more than £400,000, may be said to form the extreme western boundary of the aristocratic quarters. This arch, which bounds the Champs-Élysées, has a total height of 152 feet, and a breadth of 137. It is profusely adorned with bas-reliefs and alto-reliefs, representing victories of Napoleon, which were injured during the bombardment of Paris, but which have since undergone a complete restoration. The great streets which radiate from the Arc

de Triomphe were among the most magnificent of those constructed during the recent improvements, and they still form the finest quarter of Paris. A great avenue runs east from it to the Palace of the Tuileries, in the heart of the city.

The Palace of the Tuileries (q. v.) was begun in 1566 by Catherine de' Medici, and enlarged by successive monarchs, while used as a royal residence, until it formed a structure nearly a quarter of a mile in length, running at right angles to the Seine. To the east of the Tuileries, at a distance of more than a quarter of a mile, was erected the palace of the Louvre, forming a square of 576 feet by 538 feet, remarkable, especially the eastern façade, for its architectural beauty. The Louvre long since ceased to be a royal residence, and has been converted into a public museum of antiquities. It was connected with the Tuileries by a great picture gallery overlooking the Seine, and 1456 feet in length. North of the picture gallery, and between the two palaces, lay the Place du Carrousel, into the northern side of which, at the accession of Napoleon III., there intruded a mass of poor and narrow streets. One of the emperor's earliest improvements was to remove these buildings, and connect the Tuileries and Louvre on the northern side, throwing them into one vast building, forming the most magnificent palatial structure in the world. The Tuileries continued to be occupied as the residence of the imperial family; but the Louvre proper formed a series of great galleries filled with pictures, sculptures, and collections of Egyptian, Greek, and Roman antiquities. The Communists attempted to burn the whole pile, but only succeeded in destroying the Tuileries (of which the main part is not to be rebuilt), and a corner of the Louvre. The library of the Louvre, with its contents, was burned, but the rest of the building and its priceless treasures were saved. A large sum was voted by the government for the restoration of the Louvre, and this work was at once undertaken and carried forward with the utmost despatch. North of the injured part of the Louvre is the Palais Royal (q. v.), the most valuable part of which, fronting the Rue St Honoré, was set fire to by order of the Commune in 1871. The Palace of the Luxembourg, on the south side of the Seine, was built by Marie de' Medici in the Florentine style. It contains many magnificent rooms, some of which have been employed as picture galleries for the works of modern artists. The Luxembourg was formerly the House of the Peers, after 1871 was used as the Prefecture of the Seine, and in 1879 became the meeting-place of the French Senate. On the north bank of the Seine, opposite the Island of the Cité, stood the old Hôtel de Ville, which, before its destruction by the Commune, was one of the most magnificent buildings in Paris. It was the residence of the Prefect of the Seine, who held a sort of court there, and it included all the offices for the transaction of the municipal business of Paris. It was commenced under Francis I., but had been trebled in extent by recent additions. The statues and rich ornaments with which it was decorated were almost entirely destroyed, but steps were immediately taken to have the Hôtel carefully rebuilt in the style of its predecessor. On the island of the Cité stands the Palais de Justice, a vast building, also set fire to by the Commune; some parts of it date from the fourteenth century, and others are modern. It is the seat of some of the courts of law, as the Courts of Cassation, of Appeal, and of Police. The old palace was not much injured by the fire; but the new portion (again rebuilt) which was constructed during the reign of Napoleon

III., and much admired for its architecture, was left in ruins. Within the precincts of this palace are the Sainte Chapelle, and the noted old prison of the Conciergerie, in which Marie Antoinette, Danton, and Robespierre were successively confined.

The Conciergerie, just mentioned, in which prisoners are lodged pending their trial, constitutes one of the eight prisons of P., of which the principal is La Force. The Nouveau Bicêtre is designed for convicts sentenced to penal servitude for life; St Pélagie receives political offenders, St Lazare is exclusively for women, the Madelonnettes for juvenile criminals, and Clichy for debtors.

The number of the institutions of benevolence is enormous. The largest of the numerous hospices or alms-houses is La Salpêtrière, probably the largest asylum in the world, extending over 78 acres of land, and appropriated solely to old women, 1300 of its 4500 inmates being insane patients; Bicêtre, with nearly 3600 beds, receives only men. The Hospice des Enfants Trouvés, or Foundling Hospital, provides for the infants brought to it till they reach the age of maturity, and only demands payment in the event of a child being reclaimed. The Crèches, or public nurseries, first established in 1844, of which there are now 18, receive the infants of poor women for the day at the cost of 20 centimes. Besides institutions for the blind, deaf and dumb, convalescents, sick children, &c., P. has 17 general and special hospitals. Of these the oldest and most noted are the Hôtel Dieu, receiving annually 13,000 patients; La Charité, and La Pitié.

The chief institutions connected with the University of France, and with education generally, are still situated in the Quartier Latin. The Sorbonne (q. v.), a large building erected by Cardinal Richelieu for the faculties of the old university of Paris, contains lecture-halls and class-rooms, and an extensive library open to the public. These degrees are granted by the University of France in the faculties of science, letters, and theology, and gratuitous public lectures are delivered, which are attended by a large number of students. Near the Sorbonne is the Collège de France, where gratuitous lectures are also delivered by eminent scholars and men of letters. The Ecole Polytechnique, the School of Medicine and the School of Law, the Observatory, and the Jardin des Plantes, with its great museum of natural history, lecture-rooms, and botanical and zoological gardens, are situated in the same quarter of Paris. The principal of the public libraries are those of the Rue Richelieu, now called the Bibliothèque Nationale, which contains 2,500,000 volumes, 100,000 manuscripts, 20,000 volumes or portfolios of engravings, and a great collection of coins and medals (see LIBRARIES), which originated in a small collection of books placed by Louis XI. in the Louvre. No city on this side of the Alps is richer than P. in fine-art collections, and among these the museums at the Louvre stand pre-eminent. The Palais des Beaux-Arts is used as an exhibition of art, manufactures, and architectural models. The Hôtel Cluny, connected underground with the Palais des Thermes, in addition to its being in itself a most interesting monument of medieval art, contains curious relics of the arts and usages of the French people, from the earliest ages of their history to the Renaissance period. The Mint deserves notice for the perfection of its machinery. The Gobelins, or tapestry manufactory, may be included under the fine arts, as the productions of its looms are all manual, and demand great artistic skill. The Conservatoire des Arts et Métiers, in the Rue St Martin, contains a great collection of models of machinery, and class-rooms for the instruction of workmen in all departments of applied science. The Palace of Industry, built

in 1854 for the Universal Exhibition, now forms a permanent exhibition. The spacious building in which the Exhibition of 1878 took place was named Palace of the Trocadéro.

Among the parish churches of P. (upwards of 60 in number), the grandest and most interesting, in an historical point of view, is the cathedral of Notre-Dame, which stands on a site successively occupied by a pagan temple and a Christian basilica of the time of the Merovingian kings. The present building was constructed between the 12th and 15th centuries; and in its present state of restored magnificence, it may rank as one of the noblest specimens of Gothic architecture. St-Germain-des-Prés, which is probably the most ancient church in P., was completed in 1163; St Etienne du Mont and St Germain l'Auxerrois, both ancient, are interesting—the former for its picturesque and quaint decorations, and for containing the tomb of St Geneviève, the patron saint of P.; and the latter for its rich decorations and the frescoed portal, restored at the wish of Margaret of Valois. The Sainte Chapelle, built by St Louis in 1245–1248, for the reception of the various relics which he had brought from the Holy Land, is one of the most remarkable buildings in Paris, profusely decorated in all parts with brilliantly coloured materials. Its present beauty is entirely due to the restorations completed by the late emperor at a cost of £50,000. It was threatened by the Commune, but saved. Among modern churches are the Madeleine, built in imitation of a Greek temple, and gorgeous with gildings, frescoes, carvings, marbles, and statues; and the Pantheon, which was begun as a church, but converted by the Constituent Assembly of republican France into a temple dedicated to the great men of the nation—it was restored to the church by the late emperor, and rededicated to St Geneviève; Notre-Dame de Lorette, erected in 1823, a flagrant specimen of the meretricious taste of the day; and St Vincent de Paul, completed in 1844, somewhat less gaudy and more imposing in style; &c. Among the few Protestant churches, l'Oratoire is the largest and the best known.

P. abounds in theatres and places of amusement suited to the tastes and means of every class. The leading houses, as the Opéra, Théâtre Français—chiefly devoted to classical French drama—Odéon, Théâtre Italien, &c., receive a subvention from government, and all are under strict police supervision. The new opera-house, completed in 1875, is a wonderfully magnificent building, costing, exclusive of the site, £1,120,000. Cheap concerts, equestrian performances, and public balls, held in the open air in summer, supply a constant round of gaiety to the burgher and working classes at a moderate cost, and form a characteristic feature of P. life; while, in addition to the noble gardens of the various imperial palaces, the most densely-crowded parts of the city have public gardens, shaded by trees, and adorned with fountains and statues, which afford the means of health and recreation to the poor. Beyond the fortifications at the west of P. is the Bois de Boulogne, converted by the late emperor from a wood covered with stunted trees into one of the most beautiful gardens in Europe. That part of it which skirted the fortifications was cut up and destroyed during the siege, but since then it has been replanted, and is now as attractive to visitors as it has ever been.

P. has three large and twelve lesser cemeteries, of which the principal one is Père-la-Chaise, extending over 200 acres, and filled in every part with monuments erected to the memory of the countless number of celebrated persons who have been buried

here. The Morgue is a building in which the bodies of unknown persons who have met with a violent death are placed, and which, if not claimed within three days, are buried at the public expense. The southern parts of the city are built over beds of limestone, rich in fossils, which have been so extensively quarried as to have become a mere network of vast caverns, which in some cases scarcely afford sufficient support to the houses above. These quarries were first converted in 1784 into catacombs, in which are deposited the bones of the dead, collected from the ancient cemeteries of Paris.

P. was surrounded, under Louis-Philippe, with fortifications extending 30 miles round, and costing £5,500,000 sterling, and, in addition to these, 16 detached forts have been erected at definite distances from one another. The Champ-de-Mars is a vast sandy plain near the Quai d'Orsay, on which reviews and other military displays and national festivals are held. Close to it stands the Ecole Militaire, founded in 1752, and used as barracks for infantry and cavalry, of which it can accommodate 10,000 men, with space for 800 horses. The Hôtel des Invalides, founded in 1670 for disabled soldiers, is situated on the left bank of the river. The crypt of the church contains the sarcophagus, hewn from a huge block of Russian granite, in which lie the remains of Napoleon, deposited there in 1840.

P. is divided into 20 arrondissements. The prefect of the Seine is the chief of the municipal government, and is appointed by the government. There is a large municipal council, chosen by popular election. Each arrondissement has a maire and two assistant councillors. The prefect of police is at the head of the civic guard or gendarmes, the fire-brigade, and the sergents de ville or city police, who are armed with a sword. The cleaning, sewerage, and water supplies of P. are under the charge of the prefect. P. is now abundantly supplied with pure and wholesome water; since 1854, the length of vaulted sewers has been doubled, and now amounts to upwards of 250 miles. The same may be said in regard to the paving of the city, and the street lighting is effected by some 15,000 gas jets, and numerous electric lights. In 1818, public slaughter-houses, or abattoirs, were established at different suburbs, where alone animals are allowed to be slaughtered. Large cattle-markets are held near the licensed *Abattoirs* (q. v.). There are in the heart of the city numerous *halles*, or wholesale, and *marchés*, or retail markets. The principal of these is the Halles Centrales, near the church of St Eustache, covering nearly 20 acres. Among the older markets are the Halle aux Vins, in which 500,000 casks of wine can be stowed, and the Marché aux Fleurs.

For an account of P., see *Le Nouveau Paris*, by Labedolère; Moriac's *Paris sous la Commune* (Paris, 1871); G. A. Sala's *Paris Here and there*; and the recent editions of Hachette's, Baedeker's, and Murray's guide-books. A great work, which was to include all the principal documents connected with the history of P., was commenced during the late empire, under the supervision of M. Hausmann. Seven large quarto volumes had appeared when the work was interrupted by the events of 1871.

PARIS BASIN, the collective name of the beds of Eocene age, which rest in a hollow of the chalk in the district around Paris, where they occupy an oblong area measuring 180 miles in greatest length from north to south, and 90 miles in breadth from east to west. The different sections into which the series has been divided are given under Eocene (q. v.). The beds are chiefly remarkable for the rich harvest of organic remains which they supplied to Cuvier, and which led to the foundation of the modern science of Palaeontology. The strata from which

these were principally obtained consist of a series of white and green marls with subordinate beds of gypsum; they are largely developed at Montmartre, where the gypsum has been extensively quarried for the manufacture of plaster of Paris. The fossils consist of land and fluviatile shells, fresh-water fish and crocodiles, and the bones of birds and quadrupeds, besides a few land-plants, among which are some palms. The mammals, of which about 50 species have been described, belong to the order Pachydermata. The Paris Basin has for some time almost ceased to supply the remains of vertebrate animals.

PARIS, MATTHEW, the best Latin chronicler of the 13th c., was born about 1195, and in 1217 entered the Benedictine monastery of St Albans. After the departure of Roger of Wendover, in 1235, P. was chosen to succeed him as annalist of the monastery. He discharged his functions with veracity and boldness, in consequence of which he greatly displeased some of his contemporaries. The principal external incident of his life was his voyage to Norway, whither he was invited by King Hakon, to repair the financial disorders in the Benedictine monastery of Holm. P. landed at Bergen, 10th July 1248, was courteously received by the Norwegian monarch, and settled the business about which he came in a satisfactory manner. After his return to England, he stood high in the favour of Henry III., who used to converse with him in the most familiar manner, and from whose lips he derived not a little of the information that makes his *Chronicle* so valuable. He had also a wide circle of influential friends and acquaintances among the clergy, from whom he obtained materials for his work. His death occurred in 1259. P. had a great reputation in his day for his virtues and abilities. He was considered a universal scholar, and is said by his laudatory biographers to have been versed in mathematics, poetry, oratory, divinity, history, painting, and architecture. One thing about him long kept his memory green in the hearts of his countrymen—he was a patriotic Englishman, and though a sincere Catholic (like all good men of his age), yet he loved his country better than the pope, and wrote so fiercely against the encroachments of the court of Rome in ecclesiastical matters, that his *Chronicle* became, in after times, a great favourite with the Reformers. P.'s principal work is his *Historia Major*, which begins with the Norman Conquest, and extends to the year of the author's death. It was continued by William Rishanger, also a monk of St Albans, till the death of Henry III. in 1272. The first edition was published at London by Archbishop Parker, in 1571, and was reproduced at Zürich in 1606; later and more complete editions are those of London in 1640–1641, and in 1684. The only portion of the *Historia Major*, however, which is properly the work of P., is that extending from 1235 to 1259; the previous part being nearly a transcription from the *Flores Historiarum*, attributed to Roger of Wendover, whence some critics have supposed that P. is really the author of that work too. But this opinion is strenuously contested by the most recent editor of the *Flores Historiarum*, the Rev. H. O. Coxe (4 vols. 1841–1842). Translations both of P.'s *Chronicle* and that of Roger of Wendover have been published by Bohn in his Antiquarian Library. The British Museum, and the library of Corpus Christi College at Cambridge, contain manuscript abridgments of the *Historia Major*, made by P. himself, and entitled *Chronica Majora Sancte Albani*; a second abridgment is known as the *Historia Minor*. Other works of P.'s are *Duorum Offarum Merciorum Regum Vitæ*; *Viginti trium*

Abbatum, S. Albani Vitæ; and *Additamenta*, being explanatory additions to his *Historia Major*.

PARISH (through Fr. and Lat. from Gr. *paroikia*, habitation, *para*, near, and *oikeomai*, I dwell), the district assigned to a particular church, where the inhabitants of the district may attend at public worship, and receive the sacramental or other ministrations of the clergy. The name originally seems to have been interchangeable with *diocesis*, 'diocese,' and to have been applied to the district subject to the spiritual jurisdiction of a bishop; and, on the other hand, at a later period, *diocesis* was sometimes used to signify a parochial church or district. The distribution into parishes appears to be comparatively modern. Originally, all the clergy were (in the opinion of the Episcopalian churches) but coadjutors of the bishop, and served in his church, at which all the faithful assembled. At Alexandria, and afterwards at Rome, a number of minor churches were opened (called at Rome *tituli*), which were served by clergy, originally not permanently attached to them, but sent from the principal or bishop's church, but in progress of time fixed permanently in the charge. This, however, was not common; and we find churches, with clergy permanently attached, much earlier in rural districts than in cities. The institution does not appear to have become general till the 9th or 10th century. In England, the first legislation on the subject occurs in the laws of Edgar, about 970. The parochial division of districts seems in great measure to have followed the civil distribution into manors, or other feudal divisions of territory; and it is probable that it is to the same state of things we owe the practice of lay patronage, the priest officiating in a manorial church being chosen, with the bishop's consent, by the lord of the manor. The parochial revenue, however, by no means followed the same rules which now prevail. At first, all ecclesiastical income, from whatever district, was carried into a common fund, which was placed at the disposal of the bishop, and was generally divided into four parts—for the bishop, for the clergy, for the poor, and for the church. By degrees, however, beginning first with the rural parishes, and ultimately extending to those of the cities, the parochial revenues were placed at the disposal of the parish clergy (subject to the same general threefold division, for the clergy, for the poor, and for the church); and in some places an abusive claim, which was early reprobated, arose upon the part of the lord of the manor to a portion of the revenue. Properly, a parish has but one church; but when the district is extensive, one or more minor (*succursal*) churches, sometimes called 'chapels of ease,' are permitted.

In the law of England, a parish is an important subdivision of the country, for purposes of local self-government, most of the local rates and taxes being confined within that area, and to a certain extent self-imposed by the parties who pay them. The origin of the division of England into parishes is not very clearly ascertained by the authorities. Some have asserted that the division had an ecclesiastical origin, and that a parish was merely a district sufficient for one priest to attend to. But others have asserted that parishes had a civil origin long anterior to ecclesiastical distinctions, advantage being merely taken to ingraft these on so convenient an existing subdivision of the country; and that a parish was a subdivision of the ancient hundred, known as a vill or town, and through its machinery the public taxes were anciently collected. Hobart fixes the date of the institution of civil parishes in 1179, and his account has been generally followed. Much

difficulty has occasionally arisen in fixing the boundaries of parishes. Blackstone says the boundaries of parishes were originally ascertained by those of manors, and that it very seldom happened that a manor extended itself over more parishes than one, though there were often many manors in one parish. Nevertheless, the boundaries of parishes are often intermixed, which Blackstone accounts for by the practice of the lords of adjoining manors obliging their tenants to appropriate their tithes towards the officiating minister of the church, which was built for the whole. Even in the present day, these boundaries often give rise to litigation, and the courts have always decided the question according to the proof of custom. This custom is chiefly established by the ancient practice of perambulating the parish in Rogation-week in each year. See PERAMBULATION. There are some places as to which it is uncertain whether they are parishes or not, and hence it has been usual to call them reputed parishes. There are also places called extra-parochial places, which do not belong to any parish, such as forest and abbey lands. In these cases, the persons inhabiting were not subject to the usual parochial rates and taxes, and other incidents of parochial life. But in 1857, a statute was passed which put extra-parochial places upon a similar footing to parishes, by giving power to justices, and in some cases to the Poor-law Board, to annex them to adjoining parishes, after which they are dealt with in much the same way as other places. One of the chief characteristics of a parish is, that there is a parish church, and an incumbent and churchwardens attached to it, and by this machinery the spiritual wants of the parishioners are attended to. These several parish churches, and the endowments connected therewith, belong in a certain sense to the nation, and the incumbents are members of the Established Church of England, and amenable to the discipline of the bishops and the spiritual courts. The private patronage, or right of presenting a clergyman to an incumbency, is technically called an advowson, and is generally held by an individual as a saleable property, having a market value. The patron has an absolute right (quite irrespective of the wishes of the parishioners) to present a clerk or ordained priest of the church of England to a vacant benefice, and it is for the bishop to see to his qualifications. The bishop is the sole judge of these qualifications, and if he approves of them, the clerk or priest is instituted and inducted into the benefice, which ceremony completes his legal title to the fruits of the benefice. The incumbents of parish churches are called rectors, or vicars, or perpetual curates, the distinction being chiefly founded on the state of the tithes. When the benefice is full, then the freehold of the church vests in the rector or parson, and so does the churchyard; but he holds these only as a trustee for the use of the parishioners. There are certain duties which the incumbent of the parish church is bound by law to perform for the benefit of the parishioners. He is bound, as a general rule, to reside in the parish, so as to be ready to administer the rites of the church to them. See NON-RESIDENCE. The first duty of the incumbent is to perform public worship in the parish church every Sunday, according to the form prescribed by the Book of Common Prayer, which is part of the statute-law of England. He must adhere strictly to the forms and ceremonies, and even to the dress prescribed by the Book of Common Prayer and Canons. The incumbent is also bound to baptise the children of all the parishioners, and to administer the rite of the Lord's Supper to the parishioners not less than three times each

year. The incumbent is also bound to allow the parishioners to be buried in the churchyard of the parish, if there is accommodation, and to read the burial-service at each interment. He is also bound to marry the parishioners on their tendering themselves, and complying with the marriage acts, within the parish church and during canonical hours, and it is said he is liable to an action of damages if he refuse. In respect of burials and marriages, certain fees are frequently payable by custom; but unless such a custom exists, no fee is exigible for performance of these duties. In many cases, where one church had become insufficient for the increased population, the old parish has been subdivided under the Church Building Acts, the first of which was passed in 1818, into two or more ecclesiastical districts or parishes, for each of which a new church was built, and an incumbent appointed. The incumbents in these ecclesiastical parishes have generally been provided for by the incumbent of the mother-parish or by voluntary benefactors, and by the aid of pew-rents. But these ecclesiastical parishes, so far as the poor and other secular purposes are concerned, make no change on the old law. Another incident of the parish church is, that there must be churchwardens appointed annually, who are accordingly leading parochial officers, and whose duty is partly ecclesiastical and partly civil. Their civil duties consist chiefly in this, that they must join the overseers in many of the duties arising out of the management of the poor, and incidental duties imposed by statute. But their primary duty is to attend to the repair and good order of the fabric of the church. The common law requires that there should be two churchwardens, one of whom is appointed by the incumbent, and the other is chosen by the parishioners in vestry assembled, but sometimes this rule is varied by a local custom. This appointment and election take place in Easter-week of each year. In electing the people's churchwarden, there is often much local excitement, and it is common to poll the parish, all those who pay poor-rates being entitled to vote, the number of votes varying according to the rent, but no person having more than six votes. See CHURCHWARDENS; CHURCH RATES.

The next most important business connected with the parish is that which concerns the poor, the leading principle being that each union is bound to pay the expense of relieving its own poor. See OVERSEERS; GUARDIAN; POOR.

Another important feature of the parish is, that all the highways within the parish must be kept in repair by the parish, i. e., by the inhabitants who are rated to the poor. For this purpose, the inhabitants of each parish, in vestry assembled, appoint each year a surveyor of highways, whose duty it is to see that the highways are kept in good repair; and he is authorised, by the General Highway Act, to levy a rate on all the property within the parish. The office of a surveyor of highways is, like those of churchwarden, overseer, and guardian, a compulsory and gratuitous office. When a highway is out of repair, the mode of enforcing the repair is by summoning the surveyor of highways before justices, to shew cause why he has not repaired the road; and if the facts are not disputed, the justices either fine him, or order an indictment to be laid against the inhabitants of the parish. This indictment is tried, and the expense of it is defrayed out of the highway-rate, which is subsequently made. The highways of each parish being thus exclusively under the control of the ratepayers and their officers, it happened that great inequality prevailed in the standard of repairs which each parish set up for

itself. This led to the late Highway District Acts, first passed in 1862, the object of which is to enable the justices of the peace of the district to combine several parishes into one district, and thus secure more uniformity in the repairs of the highways. A way-warden is now appointed to represent each parish at the Highway Board, instead of the old highway surveyor; but the expenses of maintaining the highways is still ultimately paid by the parish in which they are situated, the only change being, that the expenses are ordered to be incurred by the Highway Board, instead of the parochial officer.

The above duties in reference to the parish church, the poor, and the highways, are the leading duties attaching to the parish as a parish; but over and above these, many miscellaneous duties have been imposed on the parish officers, particularly on the overseers and churchwardens, which will be found specified under the head of OVERSEERS. In nearly all cases where the parish, as a parish, is required to act, the mode in which it does so is by the machinery of a vestry. A vestry is a meeting of all the inhabitant householders rated to the poor. It is called by the churchwardens, and all questions are put to the vote. Any ratepayer who thinks the majority of those present do not represent the majority of the whole parishioners, is entitled to demand a poll. At these meetings, great excitement often prevails, especially when there existed church-rates. Wherever a parish improvement is found to be desirable, the vestry may meet and decide whether it is to be proceeded with, in which case they have powers of rating themselves for the expense. Such is the case as to the establishment of baths and wash-houses, watching, and lighting. Returns are made of all parish and local rates to parliament every year. The parish property, except the goods of the parish church, which are vested in the churchwardens, is vested in the overseers, who hold and manage the same, requiring the consent of the Poor-law Board in order to sell it. For the elementary education system, and for school-boards as local authorities of districts (not necessarily parishes), see NATIONAL EDUCATION, in SUPP. Vol. X., p. 662.

In Scotland, the division into parishes has existed from the most ancient times, and is recognised for certain civil purposes relative to taxation and otherwise, as well as for purposes purely ecclesiastical. The Court of Session, acting as the Commission of Teinds, may unite two or more parishes into one; or may divide a parish, or disjoin part of it, with consent of the heritors (or landholders) of a major part of the valuation; or apart from their consent, if it be shewn that there is within the disjoined part a sufficient place of worship, and if the Titulars of Teinds (q. v.), or others who have to pay no less than three-fourths of the additional stipend, do not object. By Act 7 and 8 Vict. c. 44, any district where there is an endowed church may be erected into a parish *quoad sacra*, for such purposes as are purely ecclesiastical. Endowed Gaelic congregations in the large towns of the Lowlands may similarly be erected into parishes *quoad sacra*.

The principal application of the parochial division for civil purposes relates to the administration of the poor-law. Under the old system the administrators of the poor-law were the kirk-session in county parishes, and the magistrates, or certain managers selected by them, in burghal parishes. The Act 8 and 9 Vict. c. 83, which remodelled the poor-law of Scotland, retained the old administrative body so long as there was no assessment; but, on a parish being assessed, substituted for it a new one, consisting in rural parishes of the owners of

heritable property of £20 yearly value, of the magistrates of any royal burgh within the bounds, of the kirk-session, a certain number of members chosen by the persons assessed; and in burghal parishes of members, not exceeding 30, chosen by the persons assessed, four members named by the magistrates, and not above four by the kirk-session or sessions. The Board of Supervision may unite two or more parishes into a combination for poor-law purposes. There is not the same extensive machinery for parochial self-government that exists in England. The burden of supporting the fabric of the church falls on the heritors, and there are no churchwardens. Highways are not repairable by the parish, and there are no elections of surveyors or way-wardens. The meeting of the inhabitants in vestry, which so often takes place in England, is unknown in Scotland, and hence the ratepayers do not interest themselves so much in local affairs. Many of the duties which in England are discharged by parochial officers, are in Scotland discharged by the sheriff-clerk, a county-officer. The system of having a Parish School (q. v.) in every parish (a system extended by the Education Act of 1872) has long prevailed in Scotland, though unknown in England till the year 1870.

PARISH CLERK, in England, is an officer of the parish of some importance, his duty being to lead the responses during the reading of the service in the parish church. He is appointed by the parson, unless some other custom of a peculiar kind exists in the parish. He must be 20 years of age, and has his office for life, but is removable by the parson for sufficient cause. By the statute 7 and 8 Vict. c. 59, a person in holy orders may be elected a parish clerk. Under some of the Church Building Acts governing the new churches built in populous parishes, he is annually appointed by the minister. The salary of the parish clerk is paid out of the church-rate.

PARISH SCHOOL. In England, prior to the recent Education Act, there was no such thing as a parish school—that is, a school existing for the benefit of the parishioners, endowed by the state, or supported by taxes on the parishioners. Every school beyond charity schools was more or less voluntary in its character, and endowed, if at all, by private benefactors. In Scotland, however, it was essential that in every parish there should be a parish school, for a statute of 1696 made it compulsory on the heritors—i. e., the chief proprietors—to provide a school-house, and to fix a salary for the teacher. If the heritors neglected to supply a school-house, the presbytery was empowered to order one at the expense of the heritors. The schoolmaster's salary was fixed according to a certain proportion, half of the rate or cess being paid by the landlord, and half by the tenant. In 1803, a statute was passed to regulate the salaries, and to give a right to the schoolmaster to have a house and garden. The office was further regulated by a later act, 24 and 25 Vict. c. 107. The salary was fixed to be from £35 to £70 per annum, to be varied and fixed by the heritors and minister of the parish, in the case of future vacancies. The qualification of the schoolmaster consisted in passing an examination conducted by the examiners of parochial schoolmasters, who were professors of the universities, who made regulations as to the time and mode of examination. For this purpose, Scotland was divided into four districts, each in connection with one of the Scotch universities. When examined, the person obtained a certificate of fitness from these examiners. The schoolmaster, who had formerly, before admission to office, been required to sign the Confession of Faith and the

formula of the Church of Scotland, and to profess that he would submit to its government and discipline, had by this act merely to make a declaration that he would not, in his office, endeavour, directly or indirectly, to teach or inculcate opinions opposed to the divine authority of the Holy Scriptures, or to the doctrines contained in the Shorter Catechism, agreed upon by the Assembly of Divines at Westminster, and approved by the General Assembly of the Church of Scotland, and that he would not exercise the functions of his office to the prejudice or subversion of the Church of Scotland as by law established. In case of misconduct, the Presbytery might complain to the Secretary of State, who would institute a commission to inquire and report, and to censure, suspend, or deprive such schoolmaster accordingly. The sheriff of the county was made the sole judge of charges of immorality, or cruel or improper treatment of the scholars, offences formerly cognizable by the Presbytery; and the heritors and minister might permit or require him to resign, and allow him a retiring allowance. Notwithstanding all these improvements, however, it continued to be apparent that the system of parish schools, however well adapted to Scotland at the Revolution, had fallen behind the requirements of the country, when the population had tripled, and large manufacturing villages and towns had sprung up in rural districts. But for denominational and other schools, vast numbers of children would have been left without the rudiments of education. By the Education (Scotland) Act, 35 and 37 Vict. c. 62 (1872), the parish schools were placed under the management of the School Board of each parish, the jurisdiction of heritors, ministers, and church courts was abolished, and every school under the management of the School Board was declared to be equally a parish school. Teachers in office before the act are not to be prejudiced by its provisions; those whom the School Boards appoint are to have such salaries assigned them as the Boards think fit, and to hold office at pleasure of the Board.

PARK (a contracted form of Middle English *parrok*, A.S. *pearroc*), a term still employed in some parts of Britain, in its original sense, to denote a field or enclosure, but more generally applied to the enclosed grounds around a mansion. The park, in this sense, includes not only the lawn, but all that is devoted to the growth of timber, pasture for deer, sheep, cattle, &c., in connection with the mansion, wherever pleasure-walks or drives extend, or the purpose of enjoyment prevails over that of economical use. *Public parks* are those in the vicinity of towns and cities, open to the public, and intended for their benefit. An increase of public parks is a pleasing feature of the present age, and not a few towns enjoy parks recently bestowed by wealthy persons somehow connected with them.

PARK, MUNGO, a celebrated African traveller, was the son of a Scottish farmer, and was born 10th September 1771 at Fowlshiels near Selkirk. He studied medicine in Edinburgh, and afterwards went to London, where he obtained the situation of assistant-surgeon in a vessel bound for the East Indies. When he returned in 1793, the *African Association* of London had received intelligence of the death of Major Houghton, who had undertaken a journey to Africa at their expense. P. offered himself for a similar undertaking, was accepted, and sailed from England 22d May 1795. He spent some months at the English factory of Pisanis on the Gambia in making preparations for his further travels, and in learning the Mandingo language. Leaving Pisanis on the 2d of December he travelled eastward; but when

he had nearly reached the place where Houghton lost his life, he fell into the hands of a Moorish king, who imprisoned him, and treated him so roughly, that P. seized an opportunity of escaping (1st July 1796). In the third week of his flight, he reached the Niger, the great object of his search, at Sego (in the kingdom of Bambarra), and followed its course downward as far as Silla; but meeting with hindrances that compelled him to retrace his steps, he pursued his way westwards along its banks to Bammakoe, and then crossed a mountainous country till he came to Kamalia, in the kingdom of Mandingo (14th September), where he was taken ill, and lay for seven months. A slave-trader at last conveyed him again to the English factory on the Gambia, where he arrived 10th June 1797, after an absence of nineteen months. He published an account of his travels after his return to Britain, under the title of *Travels in the Interior of Africa* (Lond. 1799), a work which at once acquired a high popularity. He now married and settled as a surgeon at Peebles, where, however, he did not acquire an extensive practice; so that, in 1805, he undertook another journey to Africa, at the expense of the government. When he started from Pisanis, he had a company of 45, of whom 36 were European soldiers; but when he reached the Niger in August, his attendants were reduced to seven, so fatal is the rainy season in those regions to Europeans. From Sansanding on the Niger, in the kingdom of Bambarra, he sent back his journals and letters in November 1805 to Gambia; and built a boat, in which he embarked with four European companions, and reached the kingdom of Houssa, where he and they are believed to have been murdered by the natives, or drowned as they attempted to sail through a narrow channel of the river. The fragments of information and other evidence picked up among the natives by Clapperton and Lander (q. v.), strongly confirm this view of the fate of P. and his companions. An account of P.'s second journey was published at London in 1815. P.'s narratives are of no inconsiderable value, particularly for the light which they throw upon the social and domestic life of the negroes, and on the botany and meteorology of the regions through which he passed; but he was unfortunately cut off before he had determined the grand object of his explorations—the discovery of the course of the Niger.

PARK OF ARTILLERY is the whole train of great guns with equipment, ammunition, horses, and gunners for an army in the field. It is placed in a situation whence rapid access can be had to the line of the army in any part; and at the same time where the divisions of the force can easily mass for its protection. The horses of the park are picketed in lines in its rear.

PA'RKA, the name given by Fleming to a fossil from the Old Red Sandstone, about which there has been considerable difference of opinion. The quarrymen call them 'berries,' from their resemblance to a compressed raspberry. They were compared by Fleming to the panicles of a *Juncus*, or the globose head of a *Sparganium*. Lyell thinks they resemble the egg-cases of a *Natica*, while Mantell suggested that they were the eggs of a batrachian. The opinion now most generally entertained is that they are the eggs of the *Pterygotus*.

PARKER, a family of distinction in the annals of the British navy. The founder of the family was **SIR HUGH PARKER**, an alderman of London, who received a baronetcy in 1681.—His grand-nephew, **SIR HYDE PARKER**, commanded the British fleet in the action off the Dogger Bank, 5th August 1781,

in which three Dutch ships were destroyed, and the rest of the Dutch fleet compelled to retreat into harbour. In 1783, he was appointed to the command of the British fleet in the East Indies; but the ship in which he sailed thither was lost, with all on board.—His second son, SIR HYDE PARKER, distinguished himself in the American war; blockaded the Dutch harbours with a small squadron in 1782; commanded the British fleet in the West Indies in 1795; and in 1801 was appointed to the chief command of the fleet which was sent to the Baltic to act against the armed coalition of the three northern states of Russia, Sweden, and Denmark. He had no share in the battle of Copenhagen, in which Nelson engaged contrary to his orders; but by his appearance before Carlscrona, he compelled the neutrality of Sweden; and he was on the point of sailing for Cronstadt, when the news of Paul's death put an end to hostilities.—His kinsman, SIR WILLIAM PARKER, was also a British admiral of high repute for his skill and bravery, and contributed to some of the great victories of the close of last century.—SIR PETER PARKER, who was born in 1716, and died in 1811, with the rank of admiral of the fleet, served with distinction during the Seven Years' and the American wars; and in 1782 brought the French admiral, De Grasse, a prisoner to England, for which he received a baronetcy.—SIR WILLIAM PARKER, born in 1781, commanded the frigate *Amazon* in 1806, and took, after a hard battle, the French frigate *La Belle Poule*, belonging to the squadron of Admiral Linois; and in 1809 captured the citadel of Ferrol. In 1841, he succeeded to Admiral Elliot in the command of the fleet in the Chinese seas during the first Chinese war. He took possession of Chusan, Ningpo, and Shapu; forced the entrance of the Yang-tee-kiang; and arrived under the walls of Nanking, where the treaty of peace was agreed upon. For these services, he received a baronetcy in 1844. He was afterwards appointed to the command of the fleet in the Mediterranean, and exerted himself, although in vain, to mediate between the Neapolitan government and the insurgent Sicilians. In autumn 1849, he sailed to the Dardanelles, at the request of Sir Stratford Canning (now Lord Stratford de Redcliffe), to support the Porte against the threatening demands of Austria and Russia concerning political fugitives; and in January 1850 he compelled the Greek government, by a blockade of their ports, to comply with the demands of Britain. Named in 1851 Admiral of the Blue, he resigned the command of the Mediterranean fleet to Admiral Dundas, was created Admiral of the White in 1853, Admiral of the Red in 1858, and Rear-admiral of the United Kingdom in 1862. He died in 1866.

PARKER, MATTHEW, the second Protestant Archbishop of Canterbury, was born at Norwich, August 6, 1504, studied at Corpus Christi College, Cambridge, and was ordained a priest in 1527. At the university, he was a distinguished student, especially of the Scriptures and of the history of the church, even to antiquarian minuteness; yet, in spite of his strong leaning to the past, he was from an early period favourably disposed towards the doctrines of the Reformation, and lived in close intimacy with some of the more ardent reformers. In 1533, he was appointed chaplain to Queen Anne Boleyn, who thought very highly of him, and not long before her death, exhorted her daughter Elizabeth to avail herself of P.'s wise and pious counsel. In 1535, he obtained the deanery of the monastic college of Stoke-Clare in Suffolk—*Roman Catholicism*, it must not be forgotten, being still the professed religion of the land, for Henry had not yet formally broken with the pope—and here the

studious clerk continued his pursuit of classical and ecclesiastical literature, and at the same time set himself to correct the prevailing decay of morals and learning in the church, by founding a school in the locality for the purpose of instructing the youth in the study of grammar and humanity. Here, too, he appears for the first time to have definitely sided with the reforming party in the church and state, the sermons which he preached containing bold attacks on different Catholic tenets and practices. In 1538, P. took the degree of D.D.; and in 1544, after some minor changes, became master of Corpus Christi College, Cambridge, which he ruled admirably. Three years later, he married Margaret Harlstone, the daughter of a Norfolkshire gentleman. It was probably about this time that he drew up his defence of the marriage of priests, entitled *De Conjugio Sacerdotum*. In 1552, he was presented by King Edward VI. to the canonry and prebend of Covingham, in the church of Lincoln. On the accession of Queen Mary, he refused to conform to the re-established order of things, and was (like many others of the new school of divines) deprived of his preferments, and even obliged to conceal himself. It does not appear, however, that he was eagerly sought after by the emissaries of Mary; for he was no fanatic or iconoclast, but, on the contrary, though sincerely attached to the common Protestant doctrines, very unwilling to disturb the framework of the church. P. spent at least some portion of his compulsory seclusion from public life in the enlargement of his *De Conjugio Sacerdotum*, and in translating the Psalms into English metre. The death of Mary, and the accession of Elizabeth, called him from that learned retirement of which he seems to have been sincerely fond. Sir Nicholas Bacon, now Lord-keeper of the Great Seal, and Sir William Cecil, Secretary of State, both old Cambridge friends, knew what a solid and sure judgment, what a moderate and equable spirit, and above all, what a thorough faculty for business, ecclesiastical and secular, P. had, and by their recommendation he was appointed, by the queen, archbishop of Canterbury. The consecration took place in Lambeth chapel, December 17, 1559.

'The subsequent history of Archbishop Parker,' it has been justly remarked, 'is that of the Church of England.' The difficulties that beset him were very great. Elizabeth herself was much addicted to various 'popish' practices, such as the idolatrous use of images, and was strongly, we might even say, violently, in favour of the celibacy of the clergy. She went so far as to insult P.'s wife on one occasion. But his greatest anxiety was in regard to the spirit of sectarian dissension within the bosom of the church itself. Already the germs of *puritanism* were beginning to spring up, and there can be no doubt that their growth was fostered by the despotic caprices of the queen. P. himself was manifestly convinced that if ever Protestantism was to be firmly established in the land at all, some definite ecclesiastical forms and methods must be sanctioned, to secure the triumph of order over anarchy, and so he vigorously set about the repression of what he thought a mutinous individualism incompatible with a catholic spirit. That he always acted wisely or well, cannot be affirmed; he was forced, by virtue of his very attitude, into intolerant and inquisitorial courses, and as he grew older, he grew harsher, the conservative spirit increasing with his years. To forbid 'prophesyings,' or meetings for religious discourse, was something very like persecution, though probably enough something very like treason to the church was talked in these pious conventicles.

Fuller (who must have his pun, however bad) says of him: 'He was a Parker indeed, careful to keep the fences.' Yet it must not be forgotten that it is to P. we owe the *Bishops' Bible*, undertaken at his request, carried on under his inspection, and published at his expense in 1568. He had also the principal share in drawing up the *Book of Common Prayer*, for which his skill in ancient liturgies peculiarly fitted him, and which strikingly bears the impress of his broad, moderate, and unsectarian intellect. It was under his presidency, too, that the *Thirty-nine Articles* were finally reviewed and subscribed by the clergy (1562). P. died May 17, 1575.

Among other literary performances, P. published an old Saxon Homily on the *Sacrament*, by Ælfric of St Albans, to prove that Transubstantiation was not the doctrine of the ancient English church; edited the histories of Matthew of Westminster and Matthew Paris (q. v.); and superintended the publication of a most valuable work, *De Antiquitate Britannicæ Ecclesiæ*, probably printed at Lambeth in 1572, where the archbishop, we are told, had an establishment of printers, engravers, and illuminators. He also founded the 'Society of Antiquaries,' and was its first president; endowed the university of Cambridge, and particularly his own college, with many fellowships and scholarships, and with a magnificent collection of MSS. relating to the civil and ecclesiastical condition of England, and belonging to nine different centuries (from the 8th to the 16th). Of this collection, Fuller said that it was 'the sun of English antiquity before it was eclipsed by that of Sir Robert Cotton.'

PARKER, THEODORE, an American clergyman and scholar, was born at Lexington, Massachusetts, August 24, 1810. His grandfather was captain of a militia company at the battle of Lexington, his father a farmer and mechanic, and his own boyhood was spent at the district school, on the farm, and in the workshop. At the age of 17, he taught a school, and earned money to enter Harvard College in 1830. During his collegiate course, he supported himself by teaching private classes and schools, and studied metaphysics, theology, Anglo-Saxon, Syriac, Arabic, Danish, Swedish, German, French, Spanish, and modern Greek. Entering the divinity class, at the end of his collegiate course, he commenced to preach in 1836, was an editor of the *Scriptural Interpreter*, and settled as Unitarian minister at West Roxbury in 1837. The naturalistic or rationalistic views which separated him from the more conservative portion of the Unitarians, first attracted wide notice, in consequence of an ordination sermon, in 1841, on *The Transient and Permanent in Christianity*. The contest which arose on the anti-supernaturalism of this discourse, led him to further develop his theological views in five lectures, delivered in Boston, and published (1841) under the title of *A Discourse of Matters Pertaining to Religion*, which was followed by *Sermons for the Times*. Failing health induced him to make an extended tour in Europe. In 1845, he returned to Boston, preached to large audiences at the Melodeon, and wrote for the *Dial*, *Christian Register*, *Christian Examiner*, and *Massachusetts Quarterly*. He became also a popular lecturer, and was active and earnest in opposition to slavery, the Mexican war, and the Fugitive Slave Law, for resisting which, by more than words, he was indicted. In the midst of his work, he was attacked, in 1859, with bleeding from the lungs, and made a voyage to Mexico, where he wrote his *Experience as a Minister*, whence he sailed to Italy, where he died at Florence, May 10, 1860. His works, consisting chiefly of miscellanies,

lectures and sermons, have been collected and published in America and England, in which his peculiar views in theology and politics are sustained with great force of logic and felicity of illustration. His learning was equal to his energy and philanthropy, and his influence was also great. His library of 13,000 volumes he bequeathed to the Boston Free Library. See P.'s *Life and Correspondence*, by Weiss (1864).

PARKHURST, JOHN, an English biblical scholar, the second son of John Parkhurst, Esq. of Catesby, in Northamptonshire, was born in June 1723, educated at Rugby and at Clare Hall, Cambridge, where he took his degree of M.A. in 1752, and in 1753 published *A Serious and Friendly Address to the Rev. John Wesley, in Relation to a Principal Doctrine advanced and maintained by him and his Assistants*. The doctrine assailed in P.'s pamphlet was the favourite Wesleyan doctrine of 'Assurance.' In 1762 appeared his principal work—indeed the only thing that has preserved his name—*A Hebrew and English Lexicon, without Points, adapted to the Use of Learners*. P. kept mending this Hebrew lexicon all his life. It was a very creditable performance for its time, and long continued to be the standard work on the subject among biblical students in this country; but it is disfigured by its fanciful etymologies, partly the result of his having (like many other divines of his time) adopted the irrational and presumptuous theories of Hutchinson (q. v.), and is now entirely superseded by the works of Gesenius, Ewald, and other critical scholars. P. also wrote a treatise (1787) against Dr Priestley, to prove the divinity and pre-existence of Jesus Christ. He died at Epsom, in Surrey, March 21, 1797.

PARKINSONIA, a genus of plants of the natural order *Leguminosæ*, sub-order *Cæsalpinieæ*.—*P. aculeata* is a West Indian shrub or small tree, which, when in flower, is one of the most splendid objects in the vegetable kingdom. It has pinnated leaves, with winged leaf-stalk, and large yellow flowers spotted with red. It is furnished with strong spines, and is often used for hedges, whence it is called the Barbadoes Flower Fence. It is now common in India. The bark yields a beautiful white fibre, which, however, is not very strong; but it has been suggested that it might be found suitable for paper-making.

PARLEY, in Military Language, is an oral conference with the enemy. It takes place under a flag of truce, and usually at some spot—for the time neutral—between the lines of the two armies.

PARLIAMENT (Fr. *parlement*, from *parler*, to talk), the supreme legislature of the United Kingdom of Great Britain and Ireland. The word was first applied, according to Blackstone, to general assemblies of the states under Louis VII. in France about the middle of the 12th c.; but in that country it came eventually to be the designation of a body which performed certain administrative functions, but whose principal duties were those of a court of justice.

The origin of the Parliament of England has been traced to the Saxon great councils of the nation, called 'Witten-gemote,' or meeting of wise men. These had, however, little in common with the parliaments of a later date: among other points of difference, they had a right to assemble when they pleased without royal warrant. Even under the Norman kings, the Great Council formed a judicial and ministerial as well as a legislative body, and it was only gradually that the judicial functions were transferred to courts of justice, and the ministerial to the privy council—a remnant of the judicial powers of parliament being still preserved

in the appellate jurisdiction of the House of Lords. Under the Norman kings, the council of the sovereign consisted of the tenants-in-chief of the crown, who held their lands *per baroniam*, lay and ecclesiastic. It was the principle of the feudal system that every tenant should attend the court of his immediate superior; and he who held *per baroniam*, having no superior but the crown, was bound to attend his sovereign in the Great Council or Parliament. In the charter of King John, we find for the first time trace the germ of a distinction between the peerage and the lesser nobility, the archbishops, bishops, abbots, earls, and greater barons being required to attend by a writ addressed to each, and the other tenants-in-chief by a general summons by the sheriffs and bailiffs. Baronial tenure originally made a man a baron or lord of parliament. When the offices or titles of Earl, Marquis, or Duke were bestowed on a baron, they were conferred by royal writ or patent, and at length barony came also to be conferred by writ instead of by tenure. During the 13th c., the smaller barons were allowed, instead of personally attending the national council, to appear by representatives; but the principle of representation seems first to have been reduced to a system when permission was also given to the municipalities, which, as corporations, were chief tenants of the crown, to appear by representatives. It is not quite clear when the division of parliament into two Houses took place; but when the representatives of the minor barons were joined by those of the municipalities, the term Commons was applied to both. The Lower House was early allowed to deal exclusively with questions of supply; and seems, in the reign of Richard II., to have established the right to assign the supplies to their proper uses. As the Commons became more powerful, they came to insist on the crown redressing their grievances before they would vote the supplies. The influence of parliament was on the increase during the Tudor period, while the reign of the Stewarts was characterised by a struggle for supremacy between the parliament and the crown, each striving to acquire the control of the military force of the country. The powers of the different estates came to be more sharply defined at the Revolution of 1688. On the Union with Scotland, the Parliament of England was merged into that of Great Britain. See ESTATES OF THE REALM.

In its early history, prior to the War of Independence, the Parliament of Scotland had probably not been very unlike that of England; it assembled without warrant, and consisted of bishops, earls, priors, abbots, and barons. At the close of the 13th c., the constitutional history of Scotland diverges from that of England. The addition of the burghs to the national council seems to date from the beginning of the 14th c., but it was not till much later that the lesser barons began to be exempted from attendance. The first act excusing them belongs to the reign of James I., and allows them to choose representatives called Speakers, two for each county, excepting some small counties, which were to have but one, the expenses of the representatives being defrayed by the constituency. The Scottish Parliament was never, like the English, divided into two Houses; all sat in one hall, and though it consisted of three estates, a general numerical majority of members was considered sufficient to carry a measure. The greater part of the business was transacted by the Lords of the Articles, a committee named by the parliament at the beginning of each session, to consider what measures should be passed; and whatever they recommended was generally passed without discussion. It was never held indispensable that the parliament should be summoned

by the crown, and it has even been thought that the royal assent to the measures carried was not absolutely essential. The parliament which carried the Reformation had no royal sanction. The Union was adjusted by commissioners for each country selected by the crown, and passed first, after strong and protracted opposition, in Scotland, and afterwards more easily in England.

By the act of union with Ireland in 1800 (Act 39 and 40 Geo. III. c. 67), the Irish Parliament was united with that of Great Britain as the Parliament of the United Kingdom of Great Britain and Ireland. The Parliament of Ireland had been originally formed on the model of that of England about the close of the 13th c., but it was merely the very small portion of Ireland occupied by the English settlers that was represented, which, as late as the time of Henry VII., hardly extended beyond the counties of Dublin, Louth, Kildare, and Meath, and constituted what was called the Pale. It was only for the last few years of its existence that the Irish Parliament was a supreme legislature; the English Parliament having, down to 1783, had power to legislate for Ireland. By one of the provisions of Poyning's Act, passed in 1495, no legislative proposals could be made to the Irish Parliament until they had received the sanction of the king and council in England. Act 23 Geo. III. c. 28 gave the Irish Parliament exclusive authority to legislate for Ireland, and the abuse of this power so obstructed the machinery of government, as to render the Union of 1800 matter of necessity.

The power of parliament is, according to Sir Edward Coke, so transcendent and absolute, that it cannot be confined either for persons or causes within any bounds. All remedies which transcend the ordinary courts of law are within its reach. It can alter the succession to the throne, the constitution of the kingdom, and the constitution of parliament itself. It has its own law, to be learned from the rolls and records of parliament, and by precedents and experience. One of the most thoroughly established maxims of this law is, that whatever question arises concerning either House of Parliament ought to be discussed and adjudged there, and not elsewhere. The House of Lords will not allow the Commons to interfere in a question regarding an election of a Scotch or Irish peer; the Commons will not allow the Lords to judge of the validity of the election of a member of their House, nor will either House permit courts of law to examine such cases. The authority of parliament extends to British colonies and foreign possessions. In the ordinary course of government, however, parliament does not make laws for the colonies. For some the Queen in Council legislates; others have legislatures of their own, which propound laws for their internal government, subject to the approbation of the Queen in Council; but these may be repealed and amended by parliament.

The constituent parts of parliament are the sovereign, the House of Lords, and the House of Commons. In the sovereign is vested the whole executive power; the crown is also the fountain of justice, from whence the whole judicial authority flows. To the crown is entrusted the permanent duty of government, to be fulfilled in accordance with the law of the realm, and by the advice of ministers responsible to parliament. The sovereign is also invested with the character of the representation of the majesty of the state. The sovereign's share in the legislature includes the summoning, proroguing, and dissolving of parliament. Parliament can only assemble by act of the sovereign; in but two instances have the Lords and Commons met of their own authority—viz., previously to the

Restoration of Charles II., and at the Convention Parliament summoned at the Revolution of 1688; and in both instances it was considered necessary afterwards to pass an act declaring the parliament to be a legal one. Though the queen may determine the period for assembling parliament, her prerogative is restrained within certain limits. She is bound by statute (16 Chas. II. c. 1; and 6 and 7 Will. and Mary, c. 2) to issue writs within three years after the determination of a parliament; and the practice of voting money for the public service by annual enactments, renders it compulsory for the sovereign to meet parliament every year. Act 43 Geo. III. c. 90 provides that the sovereign shall assemble parliament within fourteen days, whenever the militia shall be drawn out and embodied in case of apprehended invasion and rebellion; and a similar proviso is inserted in Act 15 and 16 Vict. c. 50, in case the present militia force should be raised to 120,000 men, and embodied. The royal assent is necessary before any measure can pass into law. The crown, as the executive power, is charged with the management of the revenues of the state, and with all payments for the public service; it is therefore the crown that makes known to the Commons the pecuniary necessities of the government, without which no supplies can be granted. The sovereign's prerogative also includes the sending and receiving of ambassadors, entering into treaty with foreign powers, and declaring war or peace. All the kings and queens since the Revolution have taken an oath at their coronation 'to govern according to the statutes in parliament agreed on, and the laws and customs of the same.' The sovereign is further bound to an adherence to the Protestant faith, and the maintenance of the Protestant religion as established by law. By the Bill of Rights (1 Will. and Mary c. 2, s. 6), and the Act of Settlement (12 and 13 Will. III. c. 2, s. 2) a person professing the popish religion, or marrying a papist, is incapable of inheriting the crown, and the people are absolved from their allegiance. This exclusion is further confirmed by the Act of Union with Scotland; and in addition to the coronation oath, every king or queen is required to take the declaration against the doctrines of the Roman Catholic Church prescribed by 30 Chas. II. c. 2, either on the throne in the House of Lords in the presence of both Houses, at the first meeting of the first parliament after the accession, or at the coronation, whichever event shall first happen. The sovereign is bound by similar sanctions to maintain the Protestant religion and Presbyterian church government in Scotland.

The province of the Houses of Parliament is to legislate with the crown, to provide supplies, to exercise a supervision over the ministers of the crown and all other functionaries, and to advise the sovereign on matters of public moment. The Upper House, from its hereditary and aristocratic character, is a check on the popular branch of the legislature and on hasty legislation.

The House of Lords may originate legislative measures of all kinds, except money-bills. Acts of grace and bills affecting the rights of peers must originate in this House. In its judicial capacity, defined by the Appellate Jurisdiction Act, 1876, it forms a court of final appeal from Her Majesty's Court of Appeal in England, from the Court of Session, Scotland, and the superior courts of law and equity of Ireland. It has a judicature in claims of peerage and offices of honour under reference from the crown. Since the union with Scotland and Ireland, it has had the power of deciding disputed elections of representative peers. It tries offenders impeached by the House of Commons, and members of its own

body on indictment found by a grand jury. The House of Lords is composed of lords spiritual and temporal. According to a declaration of the House in 1672, the lords spiritual are only lords of parliament, and not peers. They consist of 2 archbishops and 24 bishops for England, who are said to have seats in virtue of their temporal baronies. (By the act of 1869, the Irish Church, which formerly sent 4 bishops, is no longer represented.) The Bishop of Sodor and Man has no seat in parliament. On Manchester being made a see in 1847, it was arranged that one other bishop should have no seat, by a rotation not including the bishops of London, Durham, and Winchester, so as not to increase the number of the lords spiritual. The same rule was applied to the new sees, St Albans, Truro, Liverpool, Newcastle, and Southwell. The lords temporal consist of—1. The peers of England, of Great Britain, and of the United Kingdom, of whom there were, in 1886, 6 princes of the royal blood, 21 dukes, 20 marquises, 119 earls, 28 viscounts, and 274 barons. The peers of the United Kingdom may be increased without limit by new creations at the pleasure of the sovereign. 2. Sixteen representatives chosen from their own body by the peers of Scotland for each parliament. As no provision was made at the Union for any subsequent creation of Scottish peers, the peerage of Scotland consists exclusively of the descendants of peers existing before the Union. By order of the House of Lords, an authentic list of the Scottish peers was entered on the roll of peers on 12th February 1708, to which all claims since established have been added; and in order to prevent the assumption of dormant and extinct peerages by persons not having right to them, statute 10 and 11 Vict. c. 52, provides that no title standing in the roll, in right of which no vote has been given since 1800, shall be called over at an election without an order of the House of Lords. 3. Twenty-eight representatives of the Irish peerage, elected for life. Most peerages are still hereditary. Life peerages were in early times not unknown to the constitution; but in 1856, Her Majesty having created Lord Wensleydale a peer for life, the House of Lords decided he could not sit and vote. But in 1876, peers to sit as members of the House while they held the office of Lords of Appeal in Ordinary—i.e., for judicial business, but on ceasing to act as judges to be peers no longer—were created by statute. The House has also power to call to its assistance in legal and constitutional questions the judges of the Supreme Court of Judicature of all the four divisions, who advise what should be done. The House has power also to sit for judicial business during the prorogation of parliament. The votes of spiritual and temporal lords are intermixed, and the joint majority determine every question; but they sit apart on separate benches—the place assigned to the lords spiritual being the upper part of the House on the right hand of the throne. A lord may, by license from the sovereign, appoint another lord as his proxy to vote for him in his absence; but a lord spiritual can only be proxy for a lord spiritual, and a lord temporal for a lord temporal, and no member of the House can hold more than two proxies at the same time. Proxies cannot vote in judicial questions or in committees of the whole House. There are other rules and restrictions incident to the right of vote by proxy; a Lords' committee in 1867 reported that the practice of using proxies should be discontinued, but no alteration in the rules was agreed to. Peerages are lost by attainder for high treason. Neither the issue of the body of the person attainted, nor, on their failure, the descendants of the person first

called to the dignity, will be admitted to it without a removal of the attainder. But where the attainted person is tenant in tail-male, with a remainder in tail-male to another, the dignity becomes vested in the remainder man on failure of the issue of the person attainted. A peerage, whether by patent or writ, is forfeited by attainder for high treason; attainder for felony forfeits a peerage by writ, not one by patent. An attainted peerage cannot be restored by the crown, only by an act of parliament.

The House of Commons, besides its general power to introduce legislative measures, has the sole right to originate bills levying taxes, or affecting the public income and expenditure, and to examine into the validity of elections to its own body. The question whether it has any control over the rights of electors was the subject of a memorable contest between the Lords and Commons in 1704, in the cases of *Ashby and White*, and of the 'Aylesbury men' (*Hatsell's Precedents*, vol. iii.), a contest ended by the queen proroguing parliament. When inquiring into the conflicting claims of candidates for seats in parliament, the Commons have an undoubted power to determine whether electors have the right to vote. The House of Commons has the right to expel or commit to prison its own members, and to commit other persons who offend by breach of its privileges, contempt of its authority, disobedience of its orders, or invasion of its rights; but this power is limited to the duration of the session. Expulsion does not, however, create any disability to serve again in parliament. The House of Commons has also the power of impeaching offenders, who, however, are tried at the bar of the House of Lords.

The number of members of the House of Commons has varied greatly at different times. In the reign of Edward I., it seems to have been 275; in that of Edward III., 250; and of Henry VI., 300. In the reign of Henry VIII., 27 members were added for Wales, and 4 for the county and city of Chester; 4 were added for the county and city of Durham in the reign of Charles II. Between the reign of Henry VIII. and that of Charles II., 180 new members were added by the granting of royal charters to boroughs which had not previously returned representatives. Forty-five members were assigned as her proportion to Scotland at the Union, and 100 to Ireland, making the whole number of members of the House of Commons of the United Kingdom 658. The Reform Acts of 1832, 2 Will. IV. c. 45 for England, 2 and 3 Will. IV. c. 65 (amended by 4 and 5 Will. IV. c. 88, and 5 and 6 Will. IV. c. 78) for Scotland, and 2 and 3 Will. IV. c. 88 for Ireland, while leaving unaltered the whole number of members of the House of Commons, made great changes in the distribution of their seats. Fifty-six boroughs in England and Wales were entirely disfranchised; 30 which had previously returned two members were restricted to one; while 42 new boroughs were created, of which 22 were each to return two members, and 20 a single member. Several small boroughs in Wales were united to elect one member. Four members were assigned to the city of London, 2 to each of the universities of Oxford and Cambridge, and one to 133 cities and boroughs. The number of members for Scotland was increased from 45 to 53, 30 being county and 23 borough members, some of the latter representing several combined boroughs. The number of members for Ireland was increased from 100 to 105, 64 representing counties, 34 cities and boroughs, and 2 the University of Dublin. Further extensive changes in the distribution of seats were made by the recent Reform Acts of 1867

and 1868, 30 and 31 Vict. c. 102 for England, and 31 and 32 Vict. c. 48 for Scotland. The English act deprived of its second member each borough of less than 10,000 inhabitants, and altogether disfranchised seven boroughs, giving 45 seats for re-distribution, of which 25 were given to the larger counties, 11 to new boroughs, 8 to boroughs already represented, and 1 to the University of London. The Scotch act united the counties of Selkirk and Peebles into one constituency; gave a member to the universities of Edinburgh and St Andrews, and another to the universities of Glasgow and Aberdeen, a second member to each of the counties of Lanark, Ayr, and Aberdeen, and to the town of Dundee, and a third member to Glasgow; and constituted Hawick, Galashiels, and Selkirk into a new district of boroughs; the seven new seats required being provided for by a further disfranchisement of small English boroughs. The Irish Reform Act made no change in this. The number of 658 seats was thus left unaltered; but the disfranchisement of 9 English boroughs (7 in 1832) and 2 Irish ones, has reduced the number actually filled. The 652 seats occupied after the election of 1880 were thus distributed:

	Counties.	Boroughs.	Universities.	Total.
England and Wales,	187	295	5	487
Scotland,	32	26	2	60
Ireland,	64	39	2	105
	283	360	9	652

In English counties, prior to the act of 1832, the electoral qualification was founded on the holding of freehold property of the yearly value of 40s.: by that act every person who at the date was seised for his own life and that of another, or for any lives whatever, of a 40s. freehold, or who might be seised subsequently to the act if in occupation, or who might come into such freehold estate by marriage, marriage-settlement, devise, or promotion to any benefice or office, could still vote as a freeholder; but a person not included in these classes, acquiring a freehold subsequently to the act, had only the franchise when it was of the clear yearly value of £10, which value was reduced to £5 by the act of 1867. Copyholders holding an estate of £10 a year, leaseholders of that value whose leases were originally granted for 60 years, leaseholders of £50 with 20 years' leases, and tenants at will occupying lands or tenements paying a rent of £50, had the franchise under the act of 1832; and the act of 1867 reduced the franchise of copyholders and leaseholders from £10 to £5, and the occupation franchise from £50 to £12. In boroughs, the old qualification varied according to local usage, and some of the ancient rights, as that of freemen, were retained in 1832, when the franchise was bestowed on all occupiers of houses of £10 yearly value. The act of 1867 extended the borough franchise to all occupiers of dwelling-houses who have resided for 12 months on the 31st of July in any year, and have been rated to the poor-rates as ordinary occupiers, and have, on or before the 20th July, paid such rates up to the preceding 5th January, and to lodgers who have occupied for the same period lodgings of the annual value, unfurnished, of £12. In Scotland, the old county qualification consisted in being infeft in lands or superiorities holding directly of the crown of 40a. old extent (see VALUATION), or £400 Scots valued rent; and the Scotch act of 1832 reserved the rights of persons then on the roll of freeholders, or entitled to be put on it, and extended the franchise to all owners of property of the clear yearly value of £10, and to certain classes of leaseholders. By the act of 1868, the county franchise was further extended to proprietors of lands of £25 yearly value, and occupiers of the rateable value of £14. The

Scottish burghal franchise had, prior to 1832, been vested in the town-councils: the act of 1832 substituted a £10 household franchise, and that of 1868 gave the franchise to all occupiers paying rates, and to lodgers in rooms worth £10 unfurnished.
